AND WORLD OF SCIENCE.

MOTOR CYCLES.—XIII.

FIG. 80 shows a vertical section of the bottom bracket, with the spindle, chain-wheel, and the roller-clutch. Referring to the figure, A is the bracket-shell, B the barrel and eccentrics, C the spindle, D D the bearing cups, E the lock-nut which locks the left-hand cup after adjustment, F is the chain-wheel, G G two of the clutch rollers, H H is the clutch-disc screwed to the crank-boss, K K the steel clutch-ring fastened to the chain-wheel, L L is a brass cover for the clutch mechanism, fastened to the chain-wheel by eight small set-screws. The bottom bracket-shell (Fig. 81), as well as the eccentric barrel (Fig. 82), is to be cast in malleable iron, and both patterns and core-boxes will be needed for each. The two lugs, marked A A in Fig. 81, are for clamping screws to hold the eccentric barrel in position by slightly closing the ends of the shell casting. These lugs must be left loose on the pattern, being secured by a wire skewer which the moulder can withdraw. Allowance must be made for machining the barrel on the inside, and for truing-up the ends, and for boring the lugs out to fit the tubes. When making the pattern for the eccentric (Fig. 82), allow for boring right through the barrel and turning the outside faces and edges of the eccentrics. When the castings have been obtained, take the bracket-shell in hand first; grip it in a jaw-chuck, and bore out inside to 2⅝in. diameter, facing the end off at the same setting. The casting will have to be rechucked to face the opposite end. To bore out the sockets for the tubes, the casting can either be bolted to the saddle of the lathe, being packed up to get the sockets concentric with the lathe centres, and then bored with a rose bit held in a chuck; or the casting may be bolted on an angle-bracket on the face-plate, and be bored out with a boring-tool held in the tool-post of slide-rest. The angles must be as shown in Fig. 81: otherwise the frame will not come together correctly. Drill and tap the two lugs, and fit a ¼in. set-screw with a collar and square head. Next put a saw-cut through each lug, making each cut about ⅝in. long. This is to allow the set-screws to pinch the barrel on to the eccentric. To machine the eccentric, Fig. 82, will require care. Commence by boring through the barrel, making the bore the correct diameter for screwing to take the cups. The cups can be bought for 1s. 6d. per pair finished, and, with a pair of thread calipers, the diameter at the bottom of the thread easily obtained, and the eccentric bored accordingly. The bore is next chambered out to 1¾in. diameter, as shown. During these operations the casting is gripped in a jaw-chuck. A mandrel is now to be prepared with *two* centres at each end. One pair of centres must be ⁵⁄₁₆in. out of centre, which is the amount of eccentricity to be given to gripped in a jaw-chuck, centring it by the bore, and the inside at one end screwed to suit the cup. At the same setting turn and screw the projecting rim. This rim is screwed

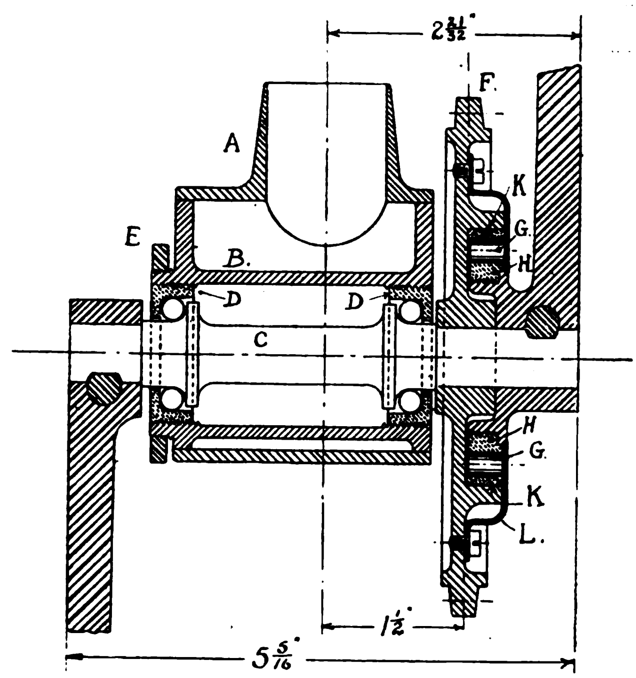

FIG. 80.

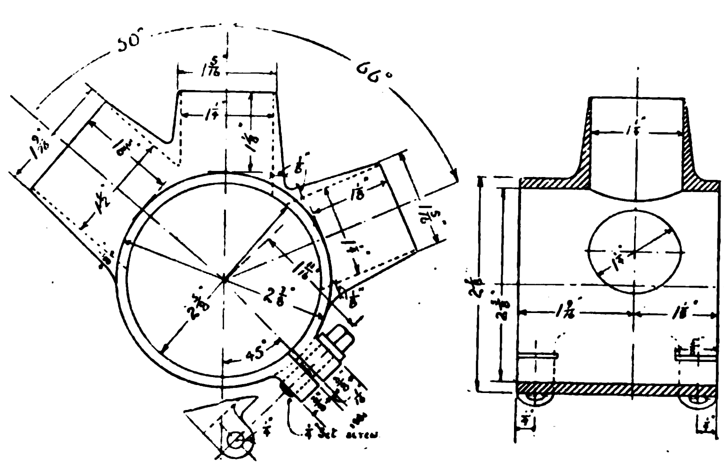

FIG. 81.

the bracket. The casting is to be driven on to this mandrel, and the edges of the eccentrics turned to 2⅜in. diameter, after which the mandrel is removed and the casting again taper, and has four saw-cuts, so that when the lock-nut, also with a taper thread, is screwed up it will grip the cup firmly. A short piece of iron is now gripped in a

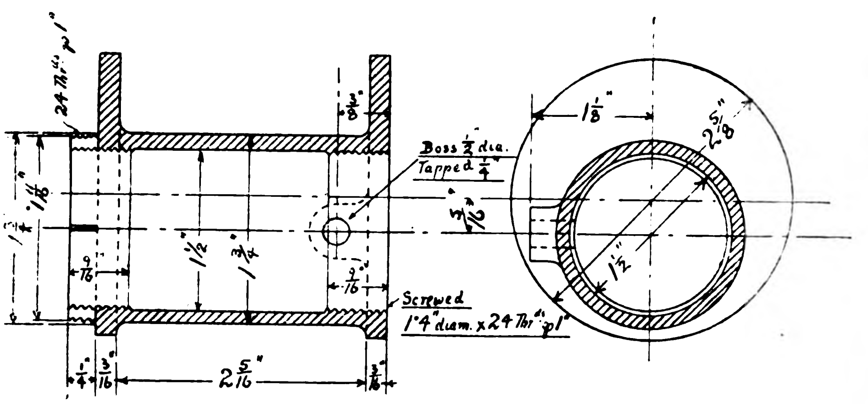

FIG. 82.

chuck and turned and screwed the same as the cups. On to this the casting is screwed by the thread cut in one end of the bore, and the opposite end then threaded. The cup at this end is prevented from slacking by a ¼in. set-screw being fitted into the boss shown behind the eccentric, a small piece of brass being interposed between the end of the screw and the cup to prevent the thread on the latter from being damaged.

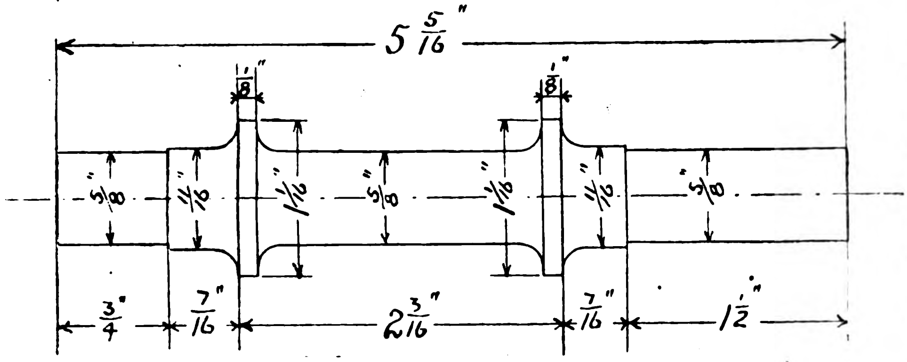

FIG. 83.

Fig. 83 is the bottom-bracket spindle. Much diversity of opinion exists as to the relative merits of cast or mild steel for this purpose. Personally, I prefer good cast steel with the ball-races hardened, the rest of the spindle being left soft. It should be turned nearly to size, and then annealed and left to cool in the ashes or buried in lime. This will minimise the risk of warping when hardening the ball-races. I recommend a gas blowpipe for heating the races, as besides being cleaner in use it is easier to localise the heat. The cranks are fitted to the spindle in the usual manner with cotter-pins, and it requires considerable care to insure the cranks being truly opposite each other. The flats on the ends of the spindle for the cotter-pins should be quite flat: if at all rounding the flats on the cotters will not bear properly, and consequently the cranks will be loose. The bottom bracket lock-nut (Fig. 84) is made of steel, and should be slightly hardened. Make it a good fit on the taper-thread on eccentric. The slots around the edge are to receive a key, formed as a fork with two projecting pins, for tightening. It will be noticed that the crank on the right hand (or chain-wheel side) of bracket has a boss to receive the clutch-disc. This is seen in detail in Fig. 85. A rough stamping of a crank should be procured, and after drilling the ⅝in. hole for the spindle, drive it on a mandrel, and turn to the dimensions given in Fig. 85. The cross-hole for cotter-pin is ⅜in. diameter, and a

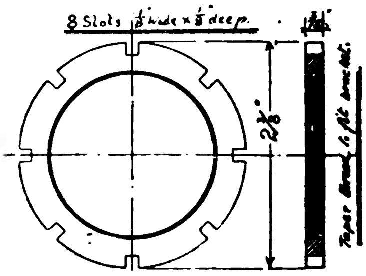

FIG. 84.

piece of ⅝in. wrought iron is to be pushed into the hole in crank-boss while drilling the cotter-hole. In all other respects this crank will be the same as its fellow, which should be bought finished.

For the chain-wheel (Fig. 86) we shall require a pattern, which must be carefully made, due allowances being made for machining the boss on both sides, turning the clutch recess, and cutting the teeth. The hole in centre and the clutch recess are lined with hardened steel, to prevent wear. The wheel, being made of malleable cast iron, would be too soft to withstand the pressure of the clutch-rollers. The steel clutch-ring is held in place by three or four small set-screws put through the malleable iron, and tapped into the steel. The inside diameter of this clutch-ring is to be exactly 2⅛in., and turned quite smooth, and must be concentric with the ⅝in. hole in chain-wheel boss. The chain-wheel teeth had better be

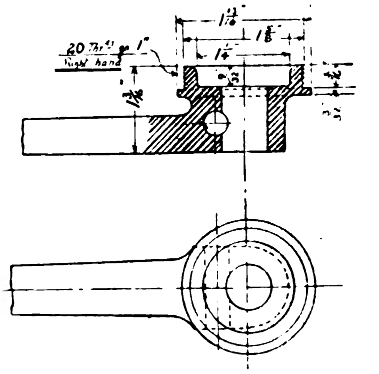

FIG. 85.

machine-cut. Any one of the chain-making firms—such as Hans Renold, Manchester—will undertake this work.

There are to be 16 teeth for a 1in. pitch block chain, ⁵⁄₁₆in. wide between side plates. It will be noticed in the section of chain wheel that the centre line of the teeth coincides with one face of the web of the wheel. The eight holes tapped ⅛in. are for the screws, with which the cover of the clutch gear is held in place. The clutch-disc, Fig. 87, is made of steel, and must be hardened and tempered a medium straw colour. There are one or two points requiring attention. The inclined faces on which the rollers cam when in use are

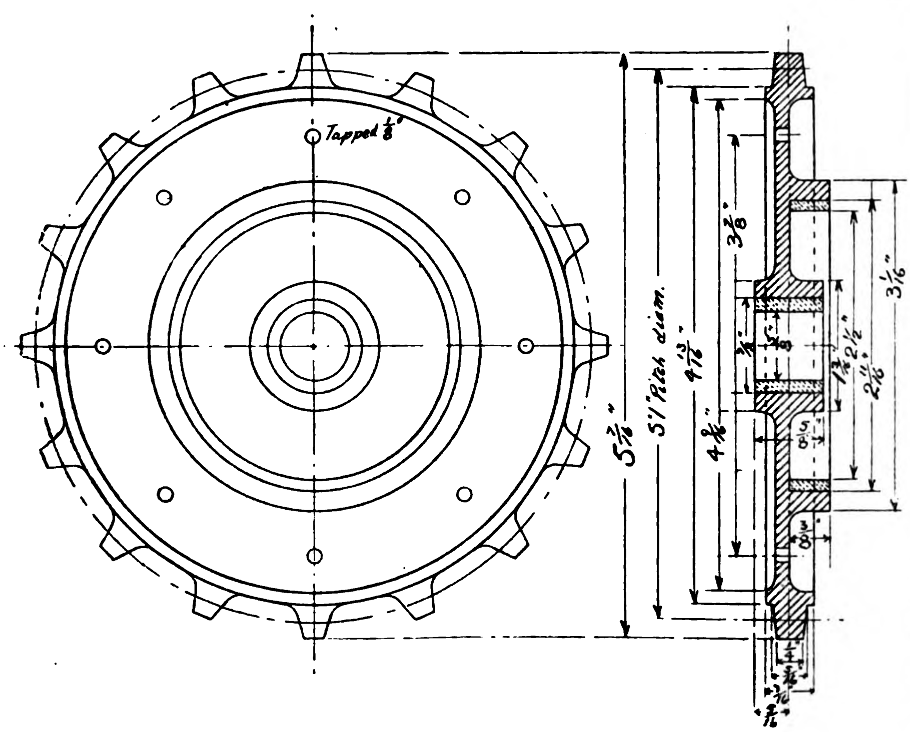

FIG. 86.

struck with a radius of $1^1/_{16}$in. from a centre which is $\frac{1}{8}$in. eccentric to the bore, and the recess is on the side facing you in Fig. 87. The exact shape of the teeth is of small moment, as they only serve to retain the rollers in place and do no work. One of the rollers is shown dotted in position. The disc is bored and screwed to fit the thread on the crank-boss, and the recess fits over the projecting collar on the same. (See Fig. 80.) The rollers are of hardened steel, $\frac{1}{4}$in. diameter by $\frac{3}{8}$in. long. Eight of them will be required, all of the same diameter. If the clutch-disc is not accurately made, and the rollers all the same diameter, there will

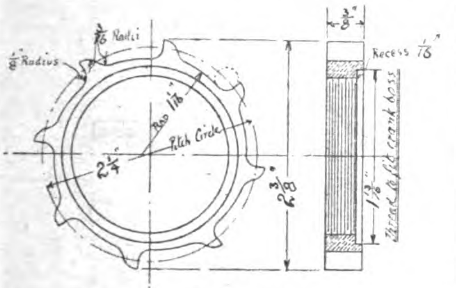

FIG. 87.

be a danger of one roller doing all the work, and probably giving way under the strain. The clutch-gear cover is seen in position in Fig. 80, being shown as a thick black line. It should be spun up out of sheet brass, No. 18 or 20 B.W.G. and nickel-plated. It is fastened to place with eight iron set-screws $\frac{1}{8}$in diameter.

ORNAMENTAL TURNING.—XXV.

By J. H. EVANS.

THE dome or spherical chuck will now claim our attention as the next in importance as belonging to this section of the ornamental turning apparatus. The value of such an addition to the lathe will be fully appreciated when it is explained that it, to some extent, aids in the production of curves and their decoration—similar to those emanating from the more costly and complex instrument (the spherical slide-rest), which will be fully treated in due course.

A short outline of its capabilities will be useful before detailing its manufacture, as it will lead up to the various points that require careful consideration.

Domes and kindred curves are obtained on solid forms by the partial rotation of the chuck when placed upon the mandrel nose. When the chuck is thus employed, in conjunction with the slide-rest only, it will be seen that we have two right-line movements. By the adjustment of the slide of the chuck by its main screw, the work is raised or depressed to or from the axis of the mandrel, in order that the desired curve may be brought to the necessary position to agree with curves to be cut. The second right-line movement is formed in the slide-rest, which places the tool or cutter also in position, with regard to the distance to or from the axis of the mandrel horizontally.

The variety of curved formations is largely increased by the interposition of the eccentric, ellipse, or rectilinear chucks—either singly or in conjunction one with the other, the semi-rotation being arrested by aid of the segment stops under the guidance of the worm-wheel and tangent screw.

We will now proceed to study the manufacture of the chuck itself, which will be found anything but a difficult undertaking. The following details of its construction will, I hope, greatly reduce what few difficulties might otherwise stand in the way of a satisfactory result in the end. By reference to Fig. 7, we see the dome chuck in its position on the lathe head, and the illustration shows the chuck in its latest and most approved form, having, as will be seen, a second worm-wheel and tangent screw at the base of the right-angle arm This improvement has many advantages, which will receive full explanation as we proceed. The chuck, then, in its primary form is composed of a strong, oblong, metal body, with a projecting boss at one end (Fig. 1). The latter is screwed to fit the mandrel-nose, and when doing this, the best way is to surface the front faces, then place it on a true surface chuck and bolt it thereto. When adjusted to the correct position—viz., the centre of the boss—the front of the boss must be turned off so that when it is screwed well home

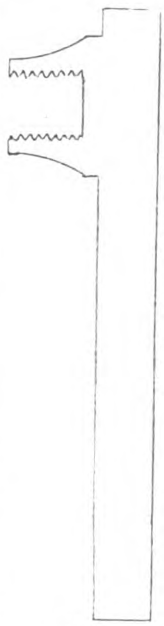

FIG. 1.

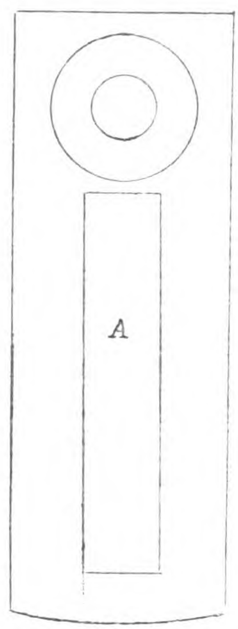

FIG. 2.

to the face of the mandrel, and the index in one of the zeros, the body will assume the vertical position. It must be then carefully turned on the front face. This done, we have the foundation from which to work, in order that all may be retained square, one part to the other.

The sides must now be filed up perfectly parallel, and from these the oblong mortise, A, Fig. 2, is got out perfectly true, and, of course, square in every way. It is necessary that great care is bestowed on this interval, as it is on this that the tenon of the right-angle arm has to work, and if unduly free in any part of the fitting it is likely to cause vibration during the progress of any cutting that may be of a severe character.

Before giving the details of the compound of material importance, but about the size mentioned is suitable in proportion.

With the right angle arm thus fitted, we have, so to speak, the foundation of the whole chuck substantially finished. I may mention that when tapping the thread in the arm we always use a steel tap, the plane part of which fits the hole in the body of the chuck, thus insuring both being in the parallel line, as the fitting guides the cutting part of the tap in the true course. On the top of body a metal end-plate is fitted by two steel screws, and countersunk out to receive the

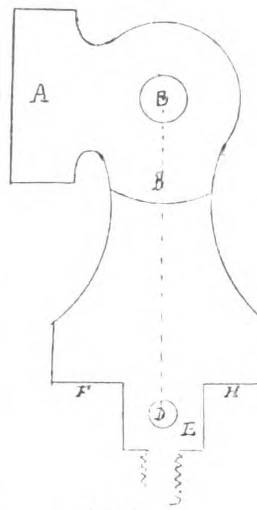

FIG. 3.

FIG. 4.

collar on the screw A, Fig. 5, the end of the screw passing through to receive the milled head by which it is actuated. When the collar is fitted to the recess, a very small portion of the face of the end-plate should be removed, so that the same may be adjusted to prevent any end-play or loss of time in the screw when in action. This is an important feature in this, as in all other chucks containing a similar movement.

The next proceeding will be to first obtain the precise centre and position of the filling to be turned in the upper part of the right-angle arm, Fig. 3, to receive the worm-wheel very. A great deal, I may say, depends upon this one feature: therefore, I must impress upon my readers not only the necessity for care in laying-out the centre, but the caution required to maintain these points when once certified. In the first instance, the centre must be in a direct line with the centre of the main screw, which passes through the tool

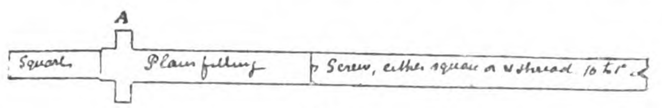

FIG. 5.

chuck—that is, the one illustrated—it will be well to just give the outline of the right-angle arm in its plan form. This is seen in Fig. 3, and thus shaped, it is fitted at E to slide in the parallel mortise A, Fig. 2. Great care must be exercised to keep the two faces F, H, Fig. 3, perfectly in agreement, so that when the nut is tightened on the screw the arm will draw up square and rigid.

We must now see that the body of the chuck and the arms are correctly bored for the reception of the screw. A $\frac{3}{8}$in. hole is accurately bored through the top part of the body, the truth retained by the opposite centre being marked on the other extremity. It is not necessary to bore a hole in this end at all, as the tendency to vibration in the screw is avoided by the arm moving along it; also the depth of the plain part being longer than is usual, it is sufficient to obviate any irregularities. The diameter of the hole bored in the body will be, of course, just in excess in diameter of that exterior of the screw; the arm is now secured in its fitting, and tightened there by its nut, a cylinder drill, fitting the long hole in body, is then used, being reduced at the cutting part which passes through the arm at D, Fig. 3, to suit the size of the tap which is to produce the thread in the same, which must be of corresponding value to all screws for similar purposes—viz., 10 threads to the inch. The diameter is not D, Fig. 3; the dotted line shows the manner in which this should be set out. It is not well to rely upon simply drilling this out: the correct way is to place the arm on a true surface chuck, and accurately centre it thereon, then either solder or bolt it securely to the chuck. The front of the arm is then turned out at the same time to fit the periphery of the worm-wheel. Fig. 4, a side view of the arm, shows how it is turned at this part. When finished on both sides, the arm should be about $\frac{3}{4}$in. wide, and the depth of the recess E, Fig. 4, $\frac{5}{16}$in., which is the width of the wheel; this will leave a filling of $\frac{5}{16}$in. in depth, sufficient to form a guide to retain the accuracy. The wheel is then fitted to move between the two faces by a screw having a large head and loose steel washer under it.

We now come to the worm-wheel, which must be made from a casting, as shown by Fig. 6, and when finished it has 96 teeth cut in the periphery. This casting is first well hardened by repeated blows from a hammer, the scale and sand being first entirely removed. It is then held by the front part A, Fig. 6, in a jaw chuck, while the other parts are reduced to truth and the sizes required. The exact size of the pin for the centre fitting is not material; but, of course, it must be made to accurately fit the hole B, Fig. 3. The necessary diameter of the wheel will be $2\frac{1}{4}$in., to

contain 96 teeth, and at this part it must fit the recess turned in the arm to accommodate it.

With this part fitted, the end of the pin B, Fig. 6, on wheel must be filed to a square, and a steel washer fitted to it, the external diameter of which should not be less than 1¼in., in order that the facial bearing at this part may correspond somewhat with that on the face of the wheel. When it bears on the opposite side of the arm, the screw-head, which holds the wheel in its place, must also have a correspondingly large head (these are both fully illustrated by Figs. 7 and 8 in the engraving of the chuck) in its place.

Our next proceeding will be the tangent screw and frame. Referring to Fig. 3 it will be seen that a projection is left on the arm at A. This is to admit of an improvement that I introduced in the action of this part. As originally made, the frame which holds the tangent screw was fixed in the position that held the screw tangential to the wheel, regardless of any desire to move it from this point. This I found in practice most inconvenient. As an instance of the advantages derived from its being fitted as described and illustrated, we will suppose that it is desired to cut a square base. This being the case, it is necessary to divide the wheel into four equal portions. Therefore, when the primary facet has been cut with the wheel fixed at 96, it will

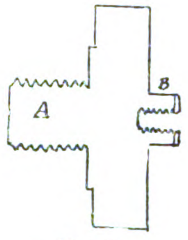

Fig. 6.

require to be moved through 24 divisions for each consecutive side—viz., 24, 48, and 72. In the absence of the power to throw the screw out of gear, it necessitates 24 revolutions of the screw for each adjustment.

It was this inconvenience that led me to make it as now shown, and all that is required to be done is to release the screw. Move the wheel round to the required point and again fix the screw in gear. Surely this must be appreciated, as the continual rotation of the winch handle for the like result can but be deemed a monotonous proceeding.

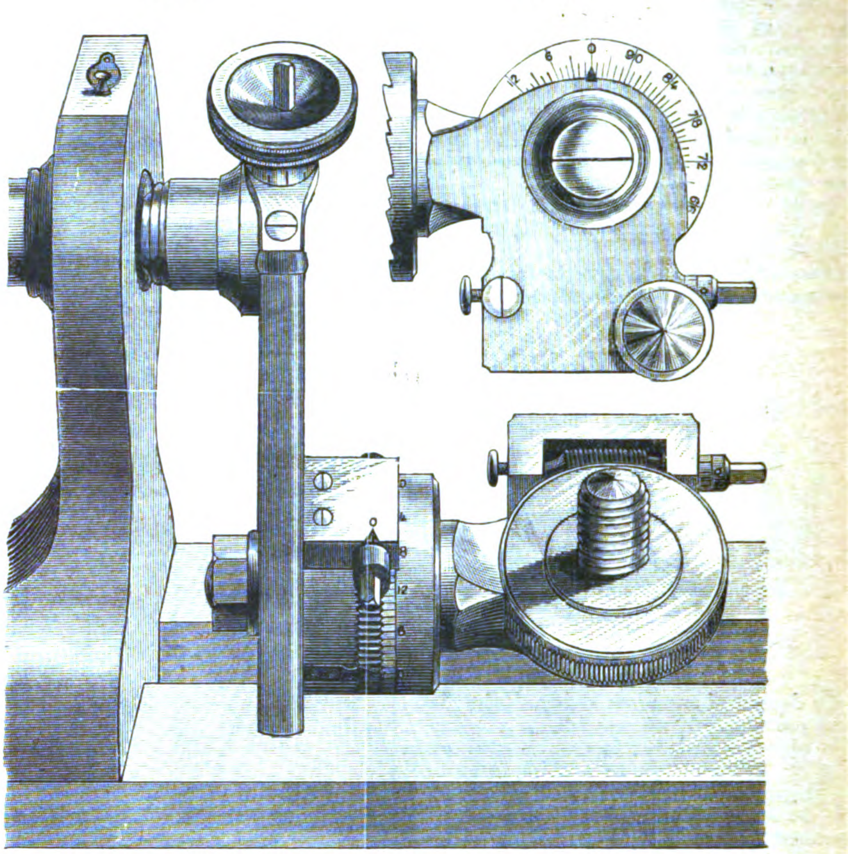
Thus, then, we have an improvement which, beyond any idea that I may have of its advantages, has been fully certified by very many of our scientific amateurs, who have adopted it to a very large extent. It will, however, be perhaps more distinctly visible as the various uses and specimens of work executed by it are approached.

We have now before us the details of what I will call the plain, or simple dome, chuck. Another improvement has been made in the shape of a second worm-wheel at the base of the right-angle arm. This is clearly illustrated by Fig. 7 and Fig. 8. The latter will also give a clear and distinct idea of the manner in which it is added. This worm-wheel forms a very important improvement to the chuck, as it enables the work to be moved to an oblique position, by which various compound shapes are formed, that cannot be obtained by any other means. It is the introduction of such novelties that renders the different instruments of a vastly more interesting character.

When making the dome-chuck on this, the latest improved plan, a circular disc with a tenon attached to it, is first fitted to the elongated slot or mortise, the lower end projecting beyond the body of the chuck in the same manner as the plain right-angle arm; at the base of the remaining portion forming the arm is another worm-wheel of 96 teeth. This is made to attach to the lower disc by a screw countersunk into the wheel, and fixing into the disc. The worm-wheel is actuated by a tangent screw, working in a metal frame, fixed also to the lower disc by two screws; on the top of the wheel the arm is attached, having a circular disc at the base by which it is fixed to the worm-wheel.

This would appear at first rather a complicated arrangement, but in reality it is perfectly simple, and is the only way the action can be obtained. The upper part is fitted up in precisely the same way as described for the plain arm, and by

Fig. 7. Fig. 8.



reference to the engraving, Figs. 7 and 8, it will become perfectly clear to all interested in it, and I should strongly recommend, when undertaking to make the chuck, to let it be in its most complete form.

A milled head is fitted to the square on the upper end of the screw. This is for the purpose of adjusting the arm to the necessary position to suit the curve or dome to be decorated. The front of this is divided into ten equal parts, and figured at every other line, 0, 2, 4, 6, and 8. This division, it may be mentioned, is seldom of much real use in adjusting hemispherical objects, the work being generally reduced approximately to form while revolving on the mandrel nose, and when transferred to the dome-chuck, it is adjusted to suit the sphere without reference to any particular starting-point or division of the micrometer in the screw. With the above remarks, I conclude what will, I think, contain every instruction for the manufacture of the dome or spherical chuck, and the continuation of the subject will have reference to the manipulation of it, accompanied by illustrations of the work effected by it.

SHORT-DISTANCE ELECTRIC POWER DISTRIBUTION.*

Long-distance transmission, especially in connection with water-power and high pressures, has attracted the attention of the electrical engineer so strongly that he has not given as much thought to the apparently smaller and less important matter of local distribution of power as the subject perhaps deserves. This is to some extent because the equipment of workshops makes little noise. In such cases electric driving is generally carried out quietly by the engineers who have charge of the works, and the consulting engineer is not called in, and there is no institution paper read anywhere, and nothing exciting happens—the machinery is merely put in and set to work. This is a great drawback; not because institution papers are specially good things, or because consulting engineers ought specially to be encouraged, though, personally, of course, I think they ought, but because it allows the subject to fall into the background in a way which is not warranted by its importance. The result is that most workshop engineers—I very nearly said millwrights, forgetting that the race is extinct now—know nothing about electrical motors, and never think of them in designing a shop. It is not that electric driving is not good enough; it is that it is never considered at all in many cases.

The most obvious places for electric-motors are those in which there is a difficulty with any other method of transmission. Mining, especially coal-mining, occurs at once as a good example. Higher efficiency, cheapness, safety, and practicability of the electric-motor put it in the front rank at once.

The next case is where scattered steam-engines are employed. Take the case of the average chemical works, for instance, or iron yard. You find a pipe supported on infrequent poles, giving a sort of cross-country excursion, every day. You know it is meant to be a steam-pipe because there is warm water leaking from all the joints, and that it is not lagged because it was considered that enough internal warmth would get along the inside to prevent freezing. If you trace this pipe out, you will find it goes to a punching-bear or shears, which are rattled around by a steam and warm water engine, which leaks too much for the water to blow its cylinder-ends off. The amount of money wasted in this way is something terrible.

In connection with docks, yards, wharves, and so on, where there are many cranes, hydraulic power distribution is generally employed. Hydraulic distribution has a great advantage when the work to to be done consists of moving something a short distance against a great force, as in the case of pressing, riveting, and pressing and drawing; but in the case of lifting, the electrical system is generally more convenient. The majority of cranes in Great Britain are probably worked by local steam-engines of the worst and most inefficient kind. Of course, where there are no facilities for anything like a central generating station, the electrical system is infinitely better than this; but compared with hydraulics the advantages are not so marked. One great drawback of the hydraulic system is the inefficiency. The ram has always enough pressure behind it to do the maximum work it will ever be called upon to do, and it uses a corresponding amount of energy every stroke, whether it really has any work to do or not. This extra energy goes into the water, and the inefficiency of the hydraulic system is easily gathered from the temperature of its water. As already remarked, the hydraulic system is best for slow thrusts; but when the mechanism involves gearing-up, the electric-motor naturally comes in, even if it has to gear down. It is more efficient to gear down than up. A hydraulic capstan, for instance, is a monstrosity.

So far we have dealt with cases in which neglect of electrical transmission is a crime. We will now pass to a larger class, in which it is merely a prevalent vice. The electrical system may be compared with its competitors in order.

The motor may replace the local steam-engine and boiler. That means generating on a larger, and therefore more economical, scale, with smaller coal

* By James Swinburne, extracted from the *Engineering Magazine*.

and oil bills, and less labour. If the local engines to be replaced have varying loads, great economy may result, because the larger engine, by averaging the load, may work at an economical load always, and its maximum power may be very much less than the aggregate power of the smaller engines. The motor has a very much higher efficiency under varying loads than the engine, so there is a fair source of economy. Unless the local engines are very large, motors can replace them with great advantage in nearly all cases. As a special instance, we may take the average ironworks. Here there are large engines, generally with local boilers dotted about, each engine working one rolling-mill. In the case of an ordinary engineering works, each shop has generally its own engine and boiler, involving access for coal, special labour, and low economy. Going back to the iron or steel works, there is general need for some local generating plant, such as the blowing-engines, which work on steady, and therefore economical, load; and there is no reason why a power-house should not be arranged at that spot for the supply of the whole system.

The next arrangement is the common vice of having a boiler which supplies one engine close to it, and feeds a distribution system of steam-piping, generally very badly lagged, which supplies small engines dotted about for running saws, cranes, or large machine tools. In such cases the motor saves an enormous waste in the steam-pipes, and attention is very much more economical as regards power.

The gas-engine is a lively competitor of the motor when the power is supplied by a central station. If gas costs, say, two shillings per thousand cubic feet, and electric energy fourpence, the cost of electrical energy comes out about six times that of gas. The difference is so great that in many cases the gas-engine is better than the electric-motor, though it has a varying load, and takes nearly the full amount of gas always, and though it needs more attention and costs more to begin with. The real reason is that the price paid for electrical energy from the central station is enormously high, on account of the capital sunk in mains, motors, and expensive sites, and on account of the expense of running and collection. In cases where the power is supplied by the consumer himself, it comes out so much cheaper that gas power cannot compete with it at all.

The great development of the electrical motor will be in taking the place of the ordinary belt and shafting transmission in all kinds of factories. In such cases, for instance, as flour-milling, where the machines run at constant speed, and approximately constant load, the opening for electric transmission is perhaps smallest; but even in that case it will probably pay. This example is taken as perhaps the worst of its kind for electrical transmission, and even here the motor has some great advantages which may make it worth while to put in electric transmission in case of new mills, even if it does not pay to change existing plant. In the first place, all the shafting and belting is taken away, and lighter buildings are necessary. Smooth working and silent running is obtained, and the efficiency is certainly increased, that is to say, smaller engine-power is needed.

In the case of cotton-spinning the same reasoning applies. The electric-motor has here a very special advantage. A properly-designed shunt machine runs at constant speed, not only with varying load, but also under varying pressure, so that the machinery can run at constant speed, even though the driving-engine varies considerably.

The driving of machine tools by motors has perhaps received more attention than all the other applications of small motors put together. As a rule, engineers arrange their own shops in a way which they would be ashamed to adopt in filling an order. There is no doubt that all tools can be best driven by motors, the only question that is open is, whether each tool should have its own motor, or whether several small tools, such as lathes, should have a shaft and one motor for the lot. The only other question of difficulty is to choose between direct current and the polyphase system. The absence of all noise from a shop is in itself by no means a particularly sentimental consideration; the disappearance of all overhead shafting has thus an advantage apart from the fitness for overhead cranes, and even small overhead runners. The small motor is, however, much less efficient than frequently supposed. There is a common idea that all dynamos and motors run up to high efficiencies, say 95 per cent. or so; but small motors are much more likely to be of the order of 59 per cent. The initial expense of small motors is their chief attribute, however, and in addition to this, machine tools are not designed for motors to begin with, but the maker sticks it on where he can, under protest, and treats it as an architect does a church organ, as an unavoidable evil, which has to be tolerated, but must not be considered. A great part of the cost of the small motor is the framework and bearings, and if the machine tool were properly designed, and the motor made by the tool-maker, this cost would be saved, for the motor and frame would take the place of the bearings and framework of other motion or reduction gear employed in connection with belt driving. At present the motor is bought as a complete mechanism from some electrical works.

Next as to varying speeds. As automatic tools come into more general use, the need for wide variations of speed become unnecessary. But in most cases variations of speed are required, and the old pulleys are kept in the machine. Probably the simplest method of getting various speeds in direct-current systems is by having several mains. Thus, a four-wire system, having 30, 60, and 120 volts, gives speed ratios of 1, 2, 3, 4, 6, and 7, which is much more than most speed pulleys. The field-magnets are always fully excited by the 210 volts across the outers, and the armature takes the various pressures. This system gives good economy, and is simple, and it costs little extra to run four wires instead of two. The question of speed is not so easily dealt with in the case of polyphase machines, as it is necessary there to have several sets of mains with different frequencies as well as different pressures, or to have more or less complicated methods of coupling the inducing element.

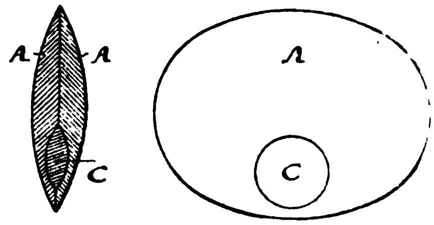
One of the greatest, and perhaps the least recognised, advantages of electrical driving without shafting is that as each machine is self-contained, the ordinary foundations can be left out. A lathe or any other tool, if decently designed, does not depend on the foundations for rigidity; the only thing the foundations do is to take up the shake communicated from outside by the belts. A self-contained machine runs better the less it is fastened down, or, to take Mr. Beaumont's motto, "If the mechanism wants to wobble, let it wobble." The stresses on all the parts, for instance, of a badly-balanced mechanism are less if the framework is not fixed to any foundations. The saving of foundations and belting as well as shafting should be credited to the motor, and the saving in wear and tear of the belting, as well as in mere coal and oil, should also be credited to the motor's running account.

In all sorts of portable tools, such as drilling, riveting, power chipping, power caulking, countersinking, and tapping, the motor is far away ahead of compressed air, steam, rotating spirals, or any other systems; and there is no reason why portable riveters and punches should not be driven electrically too.

On board ship there is a large opportunity for the introduction of electric control of steering-gear, capstans, winches, pumps, and all sorts of discharging gear. In men-of-war electricity is also applicable for working the guns, turrets, loading-gear, and similar mechanism. One obvious advantage is that the transmission system—namely, the mains, can be very easily arranged in duplicate, so that a shot is not so likely to cause disablement.

THE BIFOCAL LENS FOR EYEGLASSES.

THE bifocal lens for eyeglasses and spectacles is said to have been originated by Benjamin Franklin. For persons whose vision is of such a character that a lens that enables them to see distant objects does not enable them to see print or objects at close range, a bifocal lens is a decided convenience over the old practice of wearing two pair of spectacles, as one sees portrayed in the portraits of Patrick Henry, one pair resting on his



nose and the other pushed high upon his forehead. Those who need one lens for near vision and another for far vision will be pleased with the recent invention of Mr. Borsch.

Hitherto the bifocal lens has been made of two pieces of glass of different curvatures cemented together or confined within a frame. The line of junction of the two lenses is annoying to the sight; dirt collects in it, and it is an obstruction to the convenient wiping of the glass. The figure shows the new bifocal lens, which is said to have attracted the attention of the Franklin Society. It consists of a minor short-focus lens C C for viewing near objects, inclosed wholly within the interior of a longer focus, or less powerful lens, A, for viewing objects at a distance. The difference in magnifying power of the two lenses is obtained wholly by the difference in refractive index of the different kinds of glass of which they are made. A bifocal lens made as described is an extremely neat article, and inspection hardly discloses any difference in appearance from a simple lens.—*Popular Science*, N.Y.

THE MOST PERFECT STEAM-ENGINE.

IN the course of an article on a Forgotten Steam-Engine, the *Engineer* says:—There is, however, one invention of James Watt which has never been exploited—a fact the more remarkable in that it has given us a steam-engine which works under the most perfect thermodynamic conditions under which it is possible to employ steam to produce motive power. The fact that Watt invented the engine and patented it appears to have been quite forgotten; and although one or two inventors have patented modifications of it since, they seem to have done so in blissful ignorance of Watt's work; and the inventions have not been pushed to commercial success, so far, at least, as we know.

Those who have studied James Watt's life and works know that he left very little to be learned as to the principles on which a steam-engine should be made. In his day the science of thermodynamics did not exist as we understand it. But for all practical purposes it may, for the steam-engine, be summed up in a sentence—"Keep the cylinder hot." All the science in the world cannot tell us more than that. Watt perfectly understood, moreover, what was to be had from expansion. It is difficult, indeed, to mention any factor likely to promote the economy of the steam-engine whose existence Watt did not recognise, and whose value he did not appraise. He invented and patented the steam jacket, and he did more than this. A defect of the jacket is that while the surface to be kept hot is of almost infinitesimal thickness, the heat derived from the steam in the jacket has to pass through the metal of the cylinder liner, and the result is that the incoming and expanding steam as a rule comes in contact with metal colder than itself, and so condensation takes place. To prevent this it is necessary that the steam in the jacket should be at temperature considerably higher than that of the steam in the cylinder, a condition which can only be secured by superheating the jacket steam, or using steam of a much greater pressure than that in the cylinder. It is not, we think, necessary to pursue this subject in detail. There is a tolerably extensive literature of it in existence. The ebb and flow of heat in the walls of a cylinder have been carefully marked out by Donkin and others. Indeed, Mr. Donkin's researches on the temperature of cylinder walls, and cylinder condensation, have come to be regarded as classical.

Now, James Watt cut the Gordian knot and disposed of the whole difficulty by inventing an engine in which the cylinder is jacketed inside instead of out. Very soon after he had invented his first or atmospheric engine, he saw that the cold air following up the piston must cool the cylinder. It was clear that the difficulty could be got over by having the engine-house filled with air at the same temperature as the steam—say 215° Fahr. or so. But this was impracticable, and consequently he took the great step in advance of all former inventors of excluding the air altogether and substituting an atmosphere of steam for it. He shut up the cylinder in a little house of its own, which he kept filled with steam of high pressure, and he patented this steam-engine in 1769—that is to say, 130 years ago—and, as we hope to show in a few minutes, he then gave the world the most perfect steam-engine which, from the thermal efficiency point of view, it is possible to construct.

If our readers can refer to Bourne's "Treatise on the Steam-Engine," they will find, on p. 13, a very good drawing of Watt's 1769 engine; but its construction is so simple in all the essentials that we can make it clear, we think, without a drawing. A single-acting, open-topped vertical cylinder stands inside another. If we stand a small tumbler on a table, and turn a large tumbler upside down over it, we have the whole arrangement. The inner cylinder is fitted with a piston, the rod of which passes through a stuffing-box in the top of the outer cylinder. A couple of valves put the inner cylinder alternately in communication with the space between the two cylinders and with a jet condenser. In working, the outer cylinder is always filled with boiler steam. It is, indeed, an extension of the boiler in the same sense that the condenser is an extension of the inner cylinder. The piston-rod is coupled by a chain and arc head to the working beam; at the other end of the beam are the spear rods and pumps. When at work let us suppose the piston to be indoors, that is to say, at the bottom of the cylinder, the steam-valve opens, steam passes under the piston, balancing the pressure above, and the engine goes out-of-doors by the weight of the spears, and the forcing stroke takes place. Then the steam-valve is shut and the exhaust-valve opened, and a vacuum is made under the piston, which comes indoors, and so on. The steam under the piston could be cut off at any point which would give suitable expansion. The range was fixed by the usual limits obtaining in the case of a Cornish engine. It depends on the mass put in motion, its velocity, and resulting momentum. We need not trouble ourselves about this detail now. Because the piston is followed up on its descent by steam of full boiler pressure, the inside as well as the outside

of the cylinder must be of the temperature proper to the pressure. The steam entering the cylinder under the piston will undergo no initial condensation after the steam-valve is shut, and the expanding steam will continually meet with cylinder walls hotter and hotter than itself. The general result will be that condensation of the working steam—as we shall call it, although this distinction is not quite accurate—is out of the question. A certain amount of liquefaction due to the performance of work will take place, but no deposit of moisture on the sides of the cylinder can result. When the piston is descending the boiler steam will probably find the temperature of the cylinder walls reduced, though even this is doubtful. It may be admitted that a certain quantity of water will be produced—although certain experiments which we have carried out go to show that no condensation which can be measured takes place—as the top of the piston always passes above the top edge of the inner cylinder, any water which would otherwise collect on the piston will be pushed over, and will fall down in the space between the two cylinders, from which it can be drained. It must not be forgotten that when expansion is used a certain volume of steam will always be pushed back again into the boiler during the up-stroke of the piston, but this is of no practical importance if the steam pipe is made large.

We have here, then, an engine in which there is no initial condensation. The expanding steam starts dry in a dry, hot vessel, instead of beginning to expand with some 20 or 30 per cent. of water mixed with it. A chapter might be written on the reason why dry steam has a higher thermal efficiency than wet. Our readers who want further information on this point can consult the pages of Zeuner, or Willans, of Dwelshauvers Dery. No conditions more favourable can be found for expanding steam than those provided by Watt. We must seek for sources of waste in the boiler steam. We have repeatedly pointed out that, no matter what the quality of an engine—good, bad, or indifferent—all the steam received from the boiler by the cylinder must leave the cylinder as steam, with the exception of that percentage which is liquefied by the performance of work, and that other portion which is condensed by radiation and conduction from the outside of the engine. This means, of course, that steam condensed initially or otherwise during the stroke must be re-evaporated during the exhaust. To use the words of the veteran Isherwood, whose preface to the second volume of "Experimental Researches in Steam Engineering" is the most masterly treatise on the thermo-dynamics of the real steam-engine—not the ideal affair—ever written, we may say that it is the re-evaporation which is the cause of all the waste, because all the water of condensation, which may amount to 30 per cent. or so, has to be evaporated twice, once in the boiler and once in the cylinder, and no mechanical return is obtained for the second evaporation, which is done by the coal on the grate just as much as though it were done in the boiler. Now in the Watt engine no re-evaporation can possibly take place. We have seen that condensation of the working steam is impossible; and any water resulting from the entrance of the boiler steam into the cylinder cannot re-evaporate, because the pressure at which it was condensed remains always the same throughout the whole cycle. The evaporation takes place in an ordinary cylinder only because of the fall of pressure during the exhaust.

It is not quite clear why Watt did not build engines under his 1769 patent, or, rather, under the particular portion of it dealing with the engine we have described. The probability is that the Cornish engine, working on a totally different cycle, was more convenient. The weight of spears necessary with the earlier engine would be much in excess of that needed with the Cornish engine. A double engine might have been made with a cylinder at each end of the beam; but it would not have been easy to get mine owners to take up such an engine. A Bull engine on the system would only have exchanged one difficulty for another. The pump spears would now have to be as much too light as with a beam engine they must be too heavy. For in the Bull engine their weight would be added to the constant steam pressure forcing the piston down, just as in the beam engine they would have pulled the piston up. Yet it is possible to see how these objections might be got over, as, for instance, in a rotating or flywheel pumping-engine. Indeed, our readers will not, we think, be slow to see that this principle of construction admits of a wider range of application than Watt ever dreamed of; but with this we have nothing to do. Our work begins and ends with directing attention to an old and forgotten invention, whose beauty and excellence should suffice to rescue it from oblivion.

EVERY day the Thames scoops out of its banks 1,500 tons of mud, or half a million tons a year.

IT is reported from Rome that an agreement has been come to between the Governments of Great Britain and Italy, for the construction of a railway from Kassala to Keren and Massowah.

NEW PRIMARY BATTERY: THE HARRISON CELL.*

ALTHOUGH it was in 1793 that Volta discovered that when two discs of metal—one zinc and the other copper—were brought in close contact the zinc became charged with positive and the copper with negative electricity, it was not until 1799 that he constructed his famous primary cell. . . . . Volta's cell furnished the first practical source of electrical energy, and in a form that enabled experiments to be made which culminated in that of Faraday—the base of all our present electrical development.

I now wish to call your attention to the latest form of voltaic cell, which has been brought to perfection during this centennial year, and in which it has been aimed to embody as many as possible of the desirable qualities that the experience of the past 100 years has shown to be necessary in a good voltaic cell. Ever since Volta pointed the way, efforts have been made to devise a perfect form of voltaic cell, but so far unsuccessfully; galvanic polarisation and local action are the principal difficulties that beset the path of the inventor of primary cells.

As I shall have occasion to refer repeatedly to polarisation and local action in describing how these difficulties were overcome in the cell under consideration, I will here give the definition of these two terms as given by Park Benjamin.

"Polarisation is a condition due to the formation of a body, most commonly hydrogen, by electro-chemical decomposition upon the negative electrode, whereby a current in opposite direction to the normal current of a cell is produced, and through which the normal current may be greatly weakened."

"Local action is chemical action occurring within the cell, and is caused by the innumerable small currents which circulate between portions of the same electrode."

A great variety of chemical substances have been used as depolarisers, and even mechanical devices to utilise the oxygen of the atmosphere have been tried. The substances have usually been such as will readily give up oxygen to combine with the hydrogen to form water, and may be either liquids or solids. An objection to liquid depolarisers, besides that of having two liquids in the same cell with the accompanying porous cup or other device to keep them separated, is that but a small percentage of the total depolariser present in the cell is available for useful work, as there is generally a large amount of chemical energy left in the solution after it is too weak for satisfactory work.

Solid depolarisers are preferable to liquid ones, for which solid depolarisers one liquid only is required in the cell, and porous cups can be dispensed with, and the efficiency, or amount available for useful work, is also higher than is the case with liquid depolarisers.

The following table gives the E.M.F. of various cells in which a few of the most commonly used depolarisers—liquid and solid—are used, zinc being the positive element in each case:—

Liquid Depolarisers.	Name of Cell.	Volts.
Copper Sulphate......	Daniel	1·079
Potassium Chlorate ..	Salleron-Renoux..	1·600
Nitric Acid	Bunsen	1·900
Potassium-Bichromate	Poggendorff	2·140
Cupric Oxide	Lalande-Chaperon	0·98
Silver Chloride	De la Rue	1·03
Manganese Peroxide..	Leclanché	1·40
Mercurous Sulphate ..	Marie-Davy	1·412
Lead Peroxide........	Harrison	2·45

It is evident that the cell in which lead peroxide is the depolariser has by far the lightest E.M.F. This new cell, known as the Harrison primary cell, No. 1, is the cell that I propose to describe in this paper. It is an open-circuit primary cell, having a positive element of amalgamated zinc and a negative element of hard lead surrounded by a mass of specially prepared lead oxide (PbO_2). The electrolyte is dilute sulphuric acid, 1 to 6. The E.M.F. of the cell is 2·40—2 50 volts, the average being 2·45. The internal resistance averages ·15 ohm, therefore on short circuit the current is about 16 ampères. The negative element is in the form of a round stick, about 4in. long by 1¼in. in diameter. It is made by compressing in a special machine a mass of lead peroxide around a central conductor of hard lead that has previously been treated in a way that prevents sulphating. This conductor is provided at one end with a copper screw that passes through the cover of the jar, and is held in place by a binding post.

It is not claimed that the use of the lead peroxide for the negative element in this cell is new, for Benjamin says in his book, "The Voltaic Cell," p. 228: "In 1843 Wheatstone observed that by covering the negative electrode of a cell with a body of peroxide of lead or peroxide of manganese the E.M.F. of a cell could be greatly augmented. De la Rue reached the same conclusion at about the same period." Since then numerous inventors have tried to make a practical cell, using lead peroxide surrounding a conductor as a negative element, but the difficulty of making a peroxide that would hold together, and not disintegrate when used, has never been overcome until recently.

This seemingly insurmountable difficulty has been practically overcome in the Harrison cell after several years of experimenting. Every kind of binding material that offered any hope of success was tried, and failed, and even coating the sticks after they were made with different cements was tried, and failed. Several times it was thought that success had been achieved, as occasionally sticks would last for months without cracking or falling to pieces. Success was ultimately attained only after the trouble had been traced to its source, and special means and processes devised to prevent it.

The illustrations show Fig. 1, Harrison cell, No. 1; Fig. 2, negative element of No. 1 cell; Fig. 3, positive element of No. 1 cell.

The process of manufacture is now as follows:—The lead peroxide is prepared electrolytically, and when finished is almost chemically pure PbO^2. Certain precautions have to be observed to insure success. The neglect of any one of them gives us a peroxide that, when made into a stick, will crumble to pieces when put into the electrolyte. The proper amount of finished peroxide is then compressed around the conductor in a very ingenious machine,

* By J. D. DARLING, in the *Journal* of the Franklin Institute.

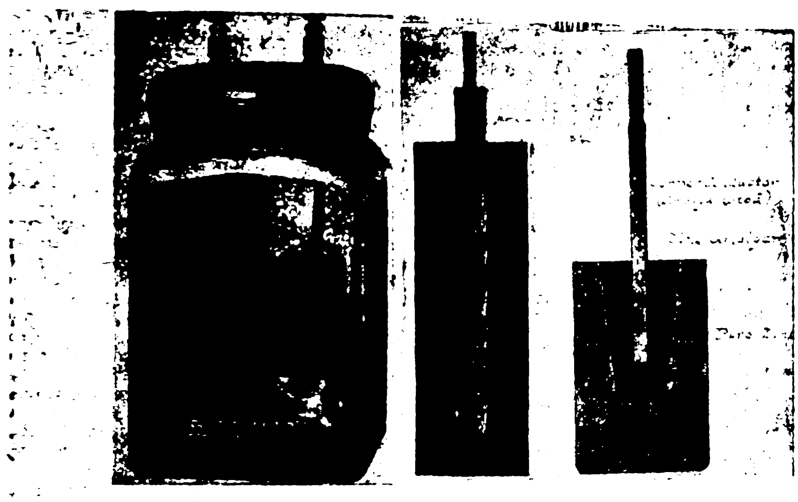


FIG. 1. FIG. 2. FIG. 3.

especially designed for the purpose, and which is worked by compressed air. The finished sticks are allowed to dry for a week or more before being made up; they are then extremely hard, and stand handling and shipment very well.

I will now proceed to describe the positive element of the cell, which also possesses some new features. At first glance it appears to be only a short rod of zinc, 1⅝in. long by 1in. in diameter, with a short conducting copper wire attached to it, but, as dilute sulphuric acid is the electrolyte used in the cell, it is plain that zinc alone would not last long, and a closer examination will show that means have been taken to keep it amalgamated. It is well known that if the zinc element in a primary cell is kept well amalgamated there is little or no local action. Kemp, of Edinburgh, was the first to point this out, in 1828, and although it would appear to be a simple matter to keep the zinc amalgamated, in reality it is not, for on account of the high specific gravity of mercury it has a constant tendency to separate from the zinc, thus leaving the zinc open to attack by the acid. To overcome this tendency the zinc element in the Harrison cell is cast in the form of a cup, and has a stout copper wire, threaded at one end for attaching the binding post imbedded in it. In this zinc cup and around the copper wire enough melted zinc amalgam is poured to completely fill it. This amalgam, when cold, is perfectly solid, and no free mercury is visible. This is a most valuable feature, as there is no mercury to spill and be lost when shipping the cell. Yet it is not necessary to amalgamate the zinc when setting up the cell, as the mercury that is in the element in the form of solid zinc amalgam is almost instantly available when it comes in contact with the exciting fluid.

What occurs when the cell is set up is as follows: Zinc amalgam is electro-positive to pure zinc, the difference in potential being 0·05 volt; therefore, when the zinc element I have described is placed in dilute acid, the first action takes place on the surface of the zinc amalgam. The zinc of the amalgam is dissolved and a minute quantity of the mercury is liberated; this, in a very short time, spreads itself over the surface of the element, and, as there is then nothing but zinc amalgam exposed to the acid, all action ceases.

The zinc element in the Harrison cell is, therefore, self-amalgamating, for it retains this property of liberating just the necessary amount of mercury needed to the end of its life. Tests have shown that the local action is very slight, and that the amount of zinc dissolved bears a close relation to the amount of energy obtained, providing the sulphuric acid used is pure. If impure acid has been used in cutting up the cell, local action will occur on the zinc. The reason for this is that the zinc is highly electro-positive in dilute sulphuric acid, and will precipitate on itself all other metals lower in the electrolytic scale, or less positive, that may happen to be in the acid used in setting up the cell.

If the metals so precipitated readily amalgamate —copper, for instance—no harm will ensue, for they will combine with the amalgamated zinc, and no local pair will be formed. But if, as is usually the case, the metallic impurities present in the end are arsenic, selenium, or iron, local action is certain to be set up, for they will be precipitated on the zinc and, as under the conditions they will not amalgamate, a multitude of local pairs are formed on the surface of the zinc element and it is rapidly consumed.

As sulphuric acid manufactured from iron or copper pyrites always contains more or less arsenic and selenium, such acid should never be used in the Harrison cell except the following precautions are strictly observed. If there is a doubt about the purity of the acid, proceed as follows:—Set up the cell as per directions, and allow it to stand for forty-eight hours. If the acid is not pure, local action will have been set up on the zinc, and gas bubbles will be seen to be rising steadily instead of adhering to the zinc. To stop the action and prevent its return, take the zinc out and scrub it off thoroughly with a stiff brush in running water. This treatment will remove the precipitated impurities from the surface of the zinc that were causing the trouble, and as there are no more left in the solution, the zinc can be replaced again, and there will be no further local action.

But it is much the better plan to use only pure 66° Baumé sulphuric acid in the Harrison cell, and if that is done there is practically no local action.

When there is an objection to the use of liquid sulphuric acid, a substitute for it in the bisulphates of potash or soda in solution can be used with almost equally good effect, providing the bisulphate used is pure.

I will conclude by calling your attention to the mechanical features of the cell and what it will do. As you may see, it is of neat and attractive appearance and of small size, being only 6in. high over all, by 3in. square. Owing to its shape, a large number occupy but a small space. The renewal of the elements is easily performed by unscrewing the binding posts, removing the exhausted elements and inserting new ones. The jar is graduated and properly marked so that no mistake can be made in putting in the right amount of acid and water when setting up the cell, and as dilute sulphuric acid is the electrolyte there are no salts to creep and corrode the connections. Primarily it is intended for open-circuit work, where only one-quarter of an ampère or less of current is required; but it can also be used on light, or what may be called semi-closed circuit work, and any desired current can be obtained by putting cells in multiple.

The cell, on ordinary household work, such as bell-ringing or gas-lighting, will last for at least one year without attention, and then, by changing the acid, it will last for some time longer before it is necessary to change the peroxide stick for a new one. The zinc generally lasts as long as two peroxide sticks; but, of course, the life of the cell depends upon the amount of work it is called upon to do. If, through defective wiring or any other cause, it is short-circuited, or, as it is called, "grounded," its life will be shortened, as would be the case with any other primary cell.

I would now call your attention to another form of cell—what is known as the "Harrison Cell, No. 3." This cell has also lead peroxide and amalgamated zinc for its elements. It has been especially designed for heavy closed-circuit work. Its E.M.F., when new, is 2·7 volts, and its life is 300 ampère-hours on a slow rate of discharge.

In this cell the negative conductor is outside the peroxide of lead, and is in the shape of a perforated basket or grid, divided internally into four equal spaces by lateral walls, and supported by a central rod passing through the cover of the jar and forming the positive terminal of the cell. By this form of construction a large negative surface in close contact with the depolariser is obtained. The entire element is of a very solid and substantial construction that is not easily injured in shipping, and, when exhausted, can be recharged and used over and over again.

The positive element is granulated zinc, lying on a copper grid on the bottom of the jar that has an insulated copper conductor passing up through the cover to form the negative terminal of the cell. To prevent local action, a quantity of mercury is placed in the bottom of the jar, which serves to keep the zinc constantly amalgamated.

Three advantages are secured by using granulated zinc. One is that because of the large surface of zinc exposed in close proximity to the negative element, the cell has a very low internal resistance and a consequently high ampèrage. Another is the ease with which the zinc can be replenished, and, thirdly, the economy obtained in the consumption of zinc. All the zinc put into the cell is used. There are no pieces left to be thrown on the scrap heap, as is the case with cells having vertical plates of zinc. Of course, there is the same need in this cell as in the No. 1 to use pure sulphuric acid, or a solution of pure bisulphate, and the same directions apply for stopping local action caused by using impure acid.

Its high E.M.F., large current, freedom from local action and the ease with which renewals can be made give this new cell distinct advantages over all other forms of what are known as closed-circuit cells. It takes a battery of three copper oxide cells coupled in series to give the voltage of one No. 3 Harrison cell. Manufacturers and users of gas and gasoline engines have long felt the need of a high-voltage primary cell to operate the spark coil attached to their engines, and I believe they will find what they have been looking for in this new cell. Physicians and dentists will also find it well adapted to their needs, and it can be used for operating coils in X-ray work, for telephones and phonographs, as well as for running small motors and fans.

Where small storage batteries are now used, this new cell will be found more convenient, for, besides having a higher E.M.F., there is not the need to send away the whole cell to have it recharged. With an extra negative element and a supply of acid and zinc, the cell can be kept running continuously with but little trouble; or, if desired, and a current is at hand, it can be used as a secondary cell.

CUTTING PRINTS: FOCUSSING SCREENS.

VERY often we find it necessary to trim our prints in all sorts of odd shapes and sizes, sometimes to suit the picture, sometimes to suit some particular unconventional mount that may have taken our fancy. When we get away into these by-paths, it is impossible to get cutting-glasses, and we have to resort to using a straightedge or square. This, however, has many disadvantages. In the first place, we cannot get a full view of the print while trimming; much time is lost in getting the print squared, and if a number have to be turned out, it is difficult to get all the prints uniform in size. Hence the advantage of a cutting-glass in allowing us to work more freely, with greater ease and rapidity.

Many photographers make their own cutting-glasses, and there are many reasons why they should be imitated in this. There is nothing difficult in it. First get a piece of crown glass cut to the required size (crown glass is handier than plate glass for all sizes up to whole plate). Any glazier will supply it at a mere nominal cost. The edges, when cut with a diamond, are left rough; but if you get a box of knife-powder, sprinkle some of it on a smooth-surface stone—old lithographic stone—or glass, moisten it so as to make a thick paste, rub the edge of the cutting-glass in this—a back and forward movement—it will very soon grind down smooth. Great care, however, must be taken to keep it from jumping, as it chips very easily at the corners. To prevent this, hold the glass firmly in both hands, keeping up a sawing movement.

Focussing-screens are ground after the same fashion. Some use fluoric acid to bite down the surface. This is a quick method, but not to be commended for focussing. Get a very fine knife-powder, and keep it moist. It is best to work on a glass surface when grinding a focussing screen. If, when finished, it is too dull, a little vaseline will improve it, and minimise the grain; but if the screen is ground with a circular motion, there should be little or no grain in it.—R. THIRSK, in the *Photographic News*.

VERMOUTH.

THE manufacture of vermouth in France is confined almost exclusively to the city of Marseilles, where all the important manufactories exist. The article is made from ordinary white wine, which is produced extensively in the region of which Marseilles is the principal centre, and which on account of its abundance is very cheap. A pure wholesome white wine may be bought in the south of France at an exceedingly low price. While returns showing the production of wine in France are published every year by the Government, no statistics are kept concerning either the production, consumption, or exportation of vermouth. The two principal points in Europe from which vermouth is exported are Marseilles and Turin. Vermouth, according to the United States Consul at Havre, is simply an infusion of certain plants and bitter aromatic herbs and roots in a quantity of wine, the degree of which has been strengthened by the addition of one-ninth

of its bulk of alcohol, in order to bring the wine, which is usually of not more than 16° alcoholic strength, up to 15°. The alcohol used should be pure, clear, and of about 85° in strength. The following are the ingredients of ordinary French vermouth:—Dry white wine, muscatel wine, wormwood, bitter orange peel, camomile, white germander, Florentine iris root, centaury, Peruvian bark, aloes, cinnamon, nutmeg, alcohol at 85°, and raspberry juice. The herbs and other ingredients are sometimes allowed to remain in the wine for a period of two months, the solution being stirred every fifteen days. After the expiration of two months the wine is drawn off into another barrel, and is allowed to remain therein for two weeks, after which it is drawn off a second time. In the event of the vermouth being cloudy, which is often the case, the manufacturer resorts to the simple process known as *collage*, which consists of stirring in some boiled milk in the proportion of one pint to 26 gallons of vermouth. The white of a single egg, well beaten, for each 26 gallons, or about half a fluid ounce of fish glue, is also used for this purpose. The vermouth should be allowed to remain in the barrel for about five days after the *collage*, after which time it may be drawn off and filtered. If the vermouth thus made is not sufficiently sweet, a little sweet wine or syrup may be added. Its degree of sweetness, however, should not exceed 5° to 7° on the Beaumé scale. Newly-made vermouth has a flavour of herbs, which is occasionally a little too pronounced. Age alone causes the disappearance of this. Certain manufacturers, instead of putting the herbs and other ingredients directly into the barrel, first inclose them in a linen sack, which is then suspended in the barrel of wine. The sack is withdrawn every five or six days, the liquid expressed from it into the wine, and the sack again suspended. It is left in the wine for a month, at the end of which time it is taken out, all the liquid pressed out of it, and the fluid thus expressed returned to the barrel. Other manufacturers first make an alcoholic extract of the ingredients, which extract is afterwards mixed with the wine in the proportions given below. To obtain alcoholic extract referred to, it is but necessary to reduce the dry ingredients mentioned to powder, and to place the same in about 10 to 12 quarts of alcohol of 85° strength. The solution is allowed to remain standing for a week, after which 19 quarts of alcohol, and 7·35 quarts of white wine are added, together with the herbs cut into small pieces. The solution is then warmed in a water bath, which should not be heated above 140° Fahr. After half an hour's warming it is removed from the fire, allowed to cool, and to remain standing for eight or nine days, during which time it should be frequently stirred in order that the sediment may be brought as much as possible in contact with the liquid. The solution, when perfectly clear, is placed in a large glass vessel, and forms an extract of vermouth. To make the article of commerce 1·58 quarts of the extract are mixed with 2·11 quarts of white wine. If, in the simple process of infusion first described, the addition of alcohol to the wine precipitates the tartar contained in the latter, and causes cloudiness, the solution should be allowed to stand a few days until it clears, after which the solid ingredients may be added. The quality of the vermouth manufactured in France depends in a great measure upon the sort of wine used. The wines most employed are those of the valley of the Rhone, certain Spanish wines, and the wines of the extreme South of France. There is a difference between the French and Italian vermouth. A number of French manufacturers make Italian vermouth, however, not for the purpose of deceiving the customer as to its origin, but merely as a type of vermouth, distinct in flavour from the article known as French vermouth. The following are the ingredients which enter into Italian vermouth:—Sweet white wine, wormwood, helenium, calamus odoratus, centaury, holy thistle, water germander, cinnamon, angelica root, gentian, nutmeg, fresh orange sliced, and alcohol at 85°. When the process of infusion, above described, is completed, the manufacturer, or an expert connoisseur identified with his manufactory, samples the vermouth in order to find whether or not it possesses the desired taste. Should the beverage be too bitter, the fault can be remedied by adding a small quantity of wine until, little by little, the proper flavour is reached. If not sufficiently bitter, a small quantity of the solid ingredients may be again infused in the wine. Nor is it necessary that vermouth should possess great alcoholic strength to be good. Some manufacturers make vermouth which contains 17° of alcohol, while others keep their product down to 12°. The average strength is from 14° to 15°.

THE SACRED MOUNTAIN OF ABYSSINIA.

IN an account of an interview with Dr. Reginald Koettlitz, which a representative of Reuter's Agency publishes, the distinguished traveller, who is a medical man, says:—Mount Zuquala, the mysterious sacred mountain of the Abyssinians, is 40 miles from the capital. It is 10,000ft. high, and in the form of a truncated cone. At its summit and in the crater is a remarkable lake, three-quarters of a mile long, which is a veritable Abyssinian Lourdes or Pool of Siloam. It is the belief of the natives that bathing in its waters will cure all diseases. Close by are some springs dedicated to the Virgin Mary. According to the popular idea, barren women need only drink of these fountains to lose their sterility. The waters are regarded with the greatest worship, and must on no account be employed for cooking, or any other useful purpose. I saw quite a number of diseased creatures round the lake shore, crawling about or being carried on litters. The whole mountain—both sides and the the crater—is densely wooded. The place is studded everywhere with hermits' huts, each of which is inhabited by holy men, who live separate lives of extreme austerity. Also hidden away in the forests are a large number of churches. I got into the good graces of the hermits by somewhat curious means. I was being shown over one of the churches, which are plentifully adorned with cheap coloured Biblical pictures "Made in Germany," when a priest with great awe drew my attention to a gaudy representation of St. George and the Dragon. I endeavoured to explain that St. George was the British as well as the Abyssinian patron saint, but the good men were very dubious, until I hit upon the idea of producing a sovereign. This at once convinced them of the truth of my statement, and proved to their complete satisfaction that I was a Christian of a very high order. The whole mountain is curious in the extreme. I was shown one tree with three trunks, united at the base, which is regarded as an emblem of the Trinity, and is hung with human hair and all sorts of trinkets. There are, too, curious crannies between the perpendicular rocks, through which it is an act of devotion to squeeze oneself. The sides of these apertures are highly polished and covered with grease, by reason of the religious activity of diseased pilgrims.

HINTS ON DEVELOPMENT FOR USE OF THE BEGINNER.*

IT may be taken for granted that no one takes up photography only for the purpose of making *negatives*, but that either prints, enlargements, lantern slides, or process blocks are the end; therefore the end, whatever it is, should never be lost sight of. Some people have an idea that the more villainous-looking the negative is the better will be the print; others always express their surprise on seeing good prints from unpromising negatives. Both these are wrong, and are simply acknowledgements that the colour of the negative has not been properly considered. Now, the colour of a negative is of great importance, whether print, enlargement, or slide is the end in view. If the colour was always alike it would not trouble us, but the latest beginner knows that negatives may be either a blue-black, or green, or brown, but it takes him some little time to discover that, while the former give flatter prints—that is, prints with less contrast than he expected—the latter give prints of the opposite character, and he is never certain till he has made a print whether the amount of colour is sufficient to make a perceptible difference in the print. It rests with the photographer whether he makes negatives which are coloured or plain; according to the developer used, so will the negatives be either black, green, or brown. Unfortunately, one of the best developers is the one most given to making brown negatives—we refer to pyro-soda—even when the pyro is kept from oxidising with meta-bisulphate, or with nitric or sulphurous acid. It seems impossible to prevent the developer from drinking oxygen while development is proceeding. To be sure, while religiously abstaining from taking the negative out of the developer to look at it, and by developing for a set time, we can make our negatives of nearly the same colour; but the very fact of abstaining from taking the plates out of the developer prevents us from taking advantage of one useful aid in development, for it is well known that by taking a plate out of the developer, and allowing the development to proceed with the aid of the developer in the film, detail in the shadows is brought up, while the high lights remain almost as they were. When pyro-soda is used, the excess of colour, which results from taking the negative out of the dish, about counterbalances the effect gained when the negative comes to be printed; so the photographer, finding uncertainty in pyro-soda, returns to pyro-ammonia, which is, after all, the best developer for all workers who are not pressed for time, and are able to spend, say, half an hour over the development of each negative. As there are only two kinds of negatives which can be properly developed—those which are the correct and those which are over-exposed—those which are under-exposed always give prints lacking in detail in the shadows. As photographs generally give too much detail, especially when properly exposed, it is advisable always either to under- or over-expose, according to the effect wished for: both under- and over-exposure rid us of the superfluous detail. The beginner should err on the side of over-exposure, then with pyro-ammonia he will be able to master his development, and not let it master him.

The first thing to be done before commencing development is to get a note-book and copy out the numbers of the plates down one side, and rule spaces for particulars of the developer used and time taken to develop opposite the numbers.

Although it is advisable to use the developer which the makers of the plates advise, we are afraid beginners—and those who are not beginners as well—do not always go to the trouble of making up fresh developer according to the formulæ given with the plates; neither can we blame them, for the quantities given by the different makers are so various, the photographer looks upon making up developers as a nuisance. In time platemakers may agree to use a universal formula. Instead of giving a long list of chemicals to be dissolved in two or three solutions, and advising the use of so much of each, it would be simpler to advise the use of so much of a standard solution for each plate.

We will suppose that the beginner has decided to develop, say, a Mawson's "Castle" plate with pyro-ammonia, which plate has had a full exposure. Let him take, instead of equal portions of the developer and the accelerator, only half the quantity of the latter, develop till as much detail and density as appear to be required, and then fix. If the plate, when finished, is wanting in either quantity, it may be taken for granted that more of the accelerator should have been used. By making careful note of the amount of accelerator used for each plate developed, the worker will build up for himself a very useful reference-book, and be able in a short space of time to make his negatives of whatever character he wishes them to be, according to the effect wanted on the particular printing paper used. At present too great contrasts seem to prevail, for the modern printing papers, gelatine, &c., require very delicate negatives. With pyro-ammonia it is much easier to get negatives suitable for gelatine papers than with pyro-soda, on account of its stain, which increases the contrasts; hydroquinone, too, generally gives negatives which are too hard for gelatine papers, though, when thoughtfully used, it is an invaluable developer for the portrait photographer. As the amateur seldom bothers himself with this class of work, we will not bore him with the reasons.

The great thing the beginner should guard against is the use of plates which easily fog in development. Owing to want of care in the manufacture, some plates are dangerously near fog point, and require much care in development. With other plates, such as Mawson's "Castle," the amateur need never fear fog; such a plate may remain in the developer for an hour while detail and density gradually appear, yet show perfectly clear glass at the edges when fixed. As it is difficult to estimate the character of a plate fogged in development, the wise photographer will have nothing to do with them. It is, of course, possible, to fog the best of plates by using an excess of ammonia or soda; but the worker who makes careful notes and measures accurately the amount of accelerator used need never fear it. One good plan is to measure out the amount of pyro, and pour this into the dish; then measure out, after having rinsed out the measure, the full amount of accelerator; and after development to measure accurately the amount of accelerator left in the measure. This deducted from the full amount gives the quantity used, which quantity should be entered, as we said, opposite the plate number in the note-book.

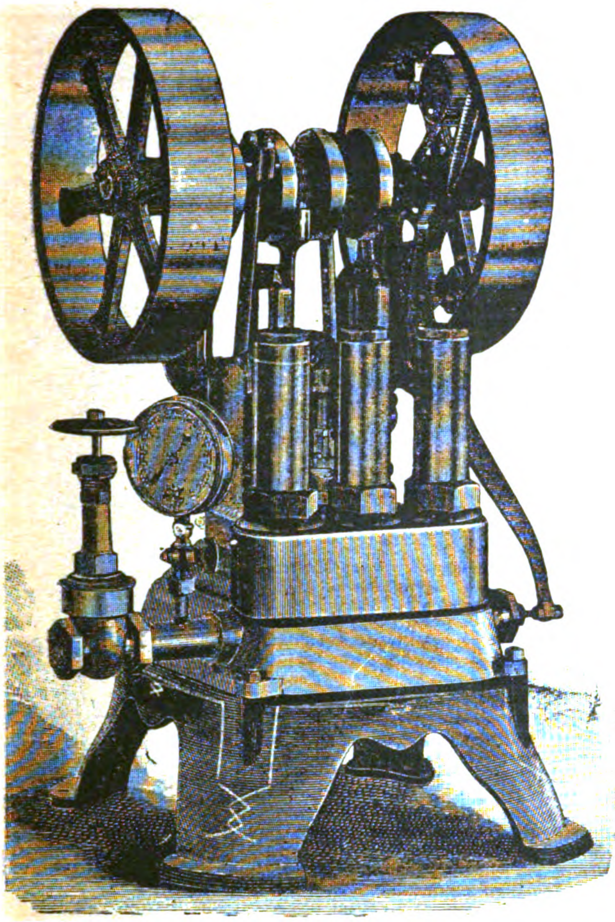
The worker will soon find that some brands of plates will stand a great amount of over-exposure, yet give perfect negatives when carefully developed, while others give hopelessly flat negatives with a generous developer. For that reason we advise the beginner to use a plate such as the "Castle," and give a full exposure.

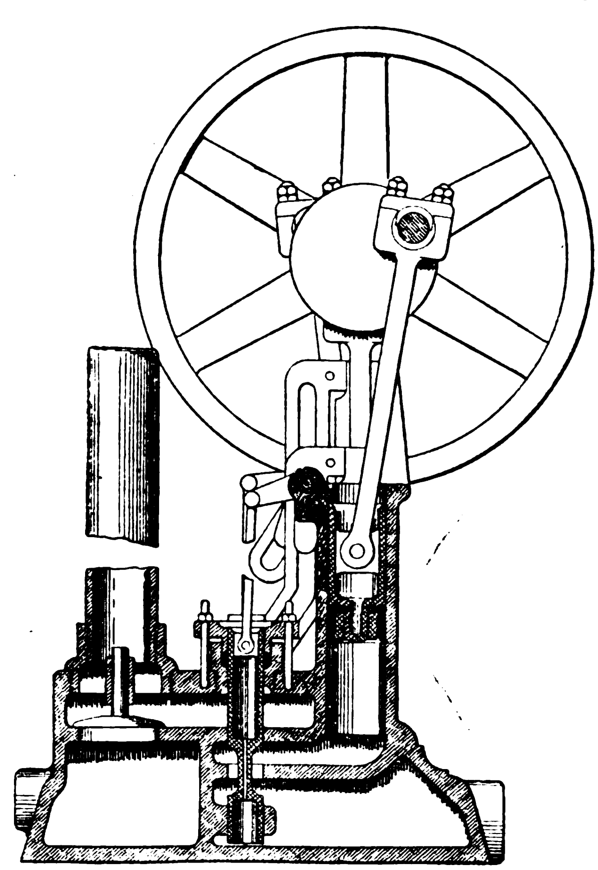
When the student has mastered the development of slow plates, then he may experiment with quick ones; the experience he has gained with slow ones will be of immense benefit, and his failures will be few, because he knows rather than guesses at what he is doing.

We have said nothing about guarding against fogging the plate by foolishly exposing it to the light of the dark-room window, as everyone knows that the safest light fogs any plate, and that all developing dishes should be covered up as much as possible. In our own practice we have a low shelf beneath our window, which keeps all light from the dish, except when we withdraw it from time to time.

There is one defect often seen in amateurs' negatives which practised workers are never troubled with—namely, air-bells, which occur during development, which leave transparent or semi-transparent spots. These are caused by either wetting the plate before development (an unnecessary proceeding), or by adding glycerine to the developer or by using citric acid as a preservative to the pyro.

* By Frank M. Sutcliffe. Extracted from the *Photographic News*.





If air-bells should appear, they can easily be removed by brushing the plate, while in the developer, with a soft camel-hair brush.

THE JOHNS HYDRAULIC ENGINE—A COMBINED WATER AND AIR MOTOR.

ONE of the most ingenious and efficient hydraulic motors which has yet appeared is being made by the Elmira Manufacturing Company, of Elmira, N.Y. The operative principle of the engine is certainly unique, embodying as it does a combination of hydraulic and air pressure. In addition to the power given by direct pressure of any given head of water, the engine employs the pressure produced by suddenly checking the momentum of the water flowing to the cylinder. In other words, the principle of the hydraulic ram is applied to the hydraulic engine without any loss of water.

The motor which forms the subject of our illustrations is a three-cylinder vertical engine, having a three-throw crankshaft, with cranks set at an angle of 120°. The three cylinders have a common supply chamber, from which separate inlets lead to the valves for each cylinder, a check valve being provided to prevent back-flow from the momentum of the water in the supply pipe. Above each inlet is an air chamber. Back of the supply chamber, underneath the cylinders, is an exhaust chamber, and between this chamber and each of the inlets are ports which lead to the bottom of the cylinders and are put successively into communication therewith. An outlet passage is carried down to the exhaust chamber, and is coupled with the exhaust pipe at a point so as to trap the water in the exhaust chamber at the end of the return stroke of each piston, without, however, exerting back pressure.

The inlet and exhaust piston valves controlling the cylinder ports are coupled with rocking levers. Cam-arms reciprocating with the pistons engage these levers so that each piston, when nearing the top of its stroke, by means of its cam-arm, actuates the valve for the next cylinder in order, holding the valve open while it pauses at the top of the stroke, and closing the valve quickly on its descent. Upon the quick closing of each valve the water will be suddenly cut off from the corresponding inlet, but will continue to flow from the supply chamber past the check-valve into the air-chamber, compressing the air until the momentum of the water is checked. The check-valve is then closed so as to maintain the air within the air-chamber in its compressed state. Upon the next opening of the valve the compressed air in the air-chamber will force the water under this increased pressure into the cylinder during the upstroke of the piston, this increased pressure gradually diminishing until the normal pressure of the water supply has been reached. The check-valve will then reopen, and the water will again flow from the supply chamber through the inlet to begin the cycle anew.

The nearness of the air-chambers to the cylinders and pistons gives an elastic action to the flow of the water, with it accumulative extra air-pressure, adds greatly to the efficiency of the motor—an efficiency of about fifty per cent. over the power obtained from the simple pressure and quantity of water alone. The elasticity of the water in following the piston allows the engine to run at a higher speed than the ordinary hydraulic motor. In the hydraulic motors commonly in use the power depends upon the volume and pressure of the water alone; but in the motor described there is the additional power obtained from compressed air. It develops a much greater power with the quantity of water used than in any other form of water motor. The engine is built in all sizes from one-quarter horse-power up, there being no more limit to size than where steam is used for motor-power. The company has its New York office at 159, Greenwich-street, and is glad to give further information to anyone desiring it.—*Scientific American.*

STORAGE BATTERIES AND ELECTRIC TRAMWAYS.

WITHIN the past few years a new field, and one which promises to be one of great magnitude, has been opened for the use of storage batteries. This is the installation of storage batteries of large size to act as regulators in connection with the trolley or third-rail system of propulsion.

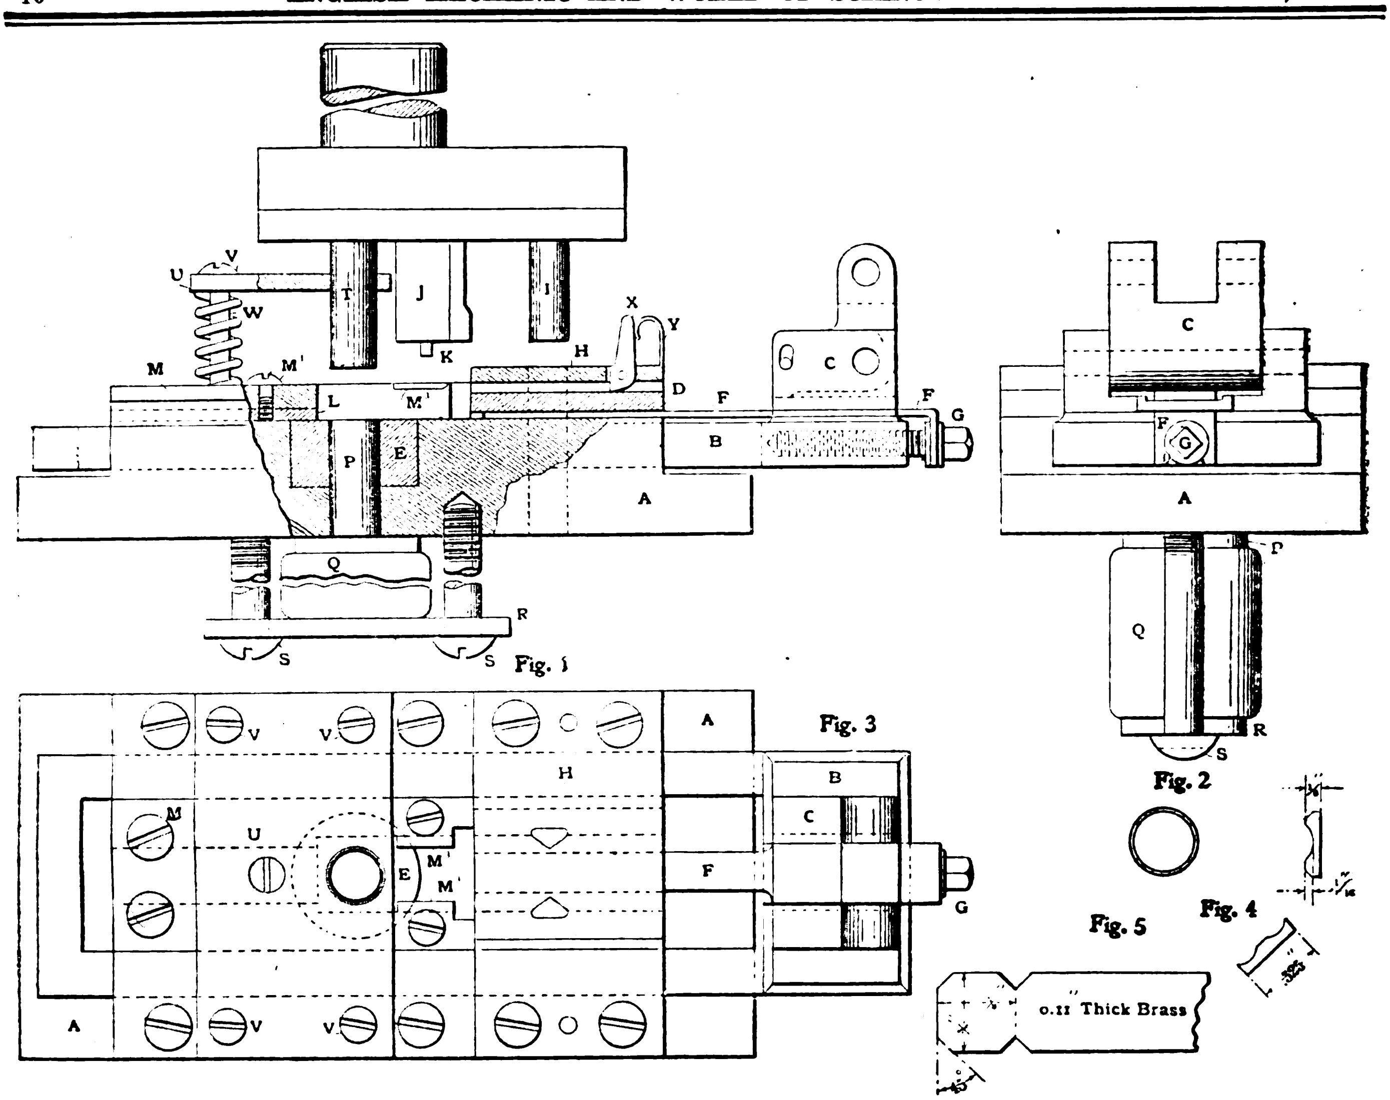
A reliable battery, properly installed will reduce the problem of generation and distribution of electric current by a street railway system to the simple question of handling an even, steady, predetermined load. Installed in the power-house, it will allow the use of a similar number of the most highly-efficient generating units, which, being operated for long periods, fully and steadily loaded, will reduce the cost of power generation to one-half of what is possible with the apparatus best suited to the variable demands made upon most railway power-houses.

A battery will take the place of all that generating machinery which is made necessary by the loads in excess of the average output. It will act absolutely instantaneously in regulating a violently fluctuating load. It is more economical to install for a continuous output of energy than a generating unit that will not have at least a full, steady load for three hours at a time, and it has the great advantage over generating machinery for such loads that, instead of sharing with the rest of the plant a fluctuating load, it is a source of additional output that, in itself, takes care of all such fluctuations and violent changes, leaving the rest of the plant fully and steadily loaded and allowing the use of a class of machinery of much higher economy than is otherwise possible. A battery further reduces the number of times a unit has to be started and stopped to follow the load-line, as with a steadily increasing load coming on the station, the battery, by discharging, can take care of it until it reaches such an extent that an additional machine can be put in service fully loaded, filling the battery again until the output increases to the capacity of the machine.

The battery, whether gaining or losing in the amount of energy stored, will still regulate for the instantaneous load changes. The same reasons apply also to the increase in size and reduction in number of generating units, as a battery, having half the output of a unit, can keep it fully loaded by discharging on first half of the increase of load and charging on the last half, at the beginning of which the machine would be thrown in. The number of running hours of the station can be materially reduced, as the night load is usually so light, for four or five hours, that it can be taken care of entirely by the battery.

A battery is also an admirable protection against flywheel accidents. For instance, in case of a short-circuit on the line the increase in current will be taken by the battery, and when the circuit-breaker goes out, the battery will keep practically the full load on the generators. When the circuit-breaker is thrown in again, the high load for the first few minutes, due to the cars starting up, will be taken care of by the battery, so that the machines will go on undisturbed even under such conditions.—Herbert Lloyd, in the Electric Railway Number of *Cassier's Magazine.*

In an article recently published in the *Zeitschrift für Angewandte Chemie*, Dr. C. O. Weber prophesies an important industrial future for the acetate of cellulose discovered by Messrs. Cross and Bevan, some two or three years ago. In many respects this body resembles the well-known nitro-celluloses, but differs from them in being non-explosive, and is able to stand a high temperature without decomposition. It is not soluble in alcohol, acetone, or ether, but dissolves in chloroform, nitro-benzine, and certain other bodies. It is an excellent insulator, its resistance being greater than that of either guttapercha or indiarubber, and it is suggested, therefore, as a substitute for mica as an electric insulator, whilst in other applications it should replace celluloid.



DIE CONSTRUCTION.*

IN the *American Machinist* of Feb. 23 (see p. 124, March 24) I gave a description of a combination punch and die for piercing, shearing, bending, and forming a piece of sheet metal. The present article illustrates a die for shearing and drawing a piece of sheet metal into the form of a cup with irregular edges. The principle of the two dies is identical as far as the automatic feeding of the strip of metal is concerned. In details of construction and operation they differ. The finished piece, being entirely different from the previous one, calls for a different combination of mechanical movements. The arranging of combinations of mechanical movements, guided by a knowledge of how a piece of metal will act under different conditions, constitutes up-to-date die-making in certain lines of work.

In the drawing, Fig. 1 is a side elevation, and Fig. 2 an end elevation of the die-bed and slide, the punch being left out of this view, as it would not add materially to the description without overcrowding the drawing. Fig. 3 is a plan, Fig. 4 (three views) being the finished article. Fig. 5 shows the strip of metal, ·011in. thick and ⅝in. wide, with two notches cut by the shearing punches I. The metal to the left of the dotted line shows the outline of the blank that forms the piece Fig. 4.

A, Figs. 1, 2, and 2, is designed to show a cast-iron die-bed carrying the slide B. The grip C, its connection to the press and method of operation are identical with that in the reference before given. In this instance it is necessary that the piece of metal that forms the finished article be severed from the strip before any action of forming takes place. The shearing die D is therefore raised above the level of the drawing-die E, and slotted to accommodate an auxiliary slide F made adjustable by means of the shoulder screw G.

The strip of metal passing between the shearing-die D and the stripper gauge H has the notches cut by the shearing punches I. Feeding the length of one blank, the final cut is made by the shearing punch J. This punch is provided with a pin K held out by means of a very sensitive spiral spring; just enough spring being provided to insure the fact that the blank after being severed from the strip, will not draw back, but will lie in front of the slide F.

Upward movement of the ram carries the strip of metal forward for another blank, and the blank already cut is carried over the drawing-die E. The projections M 3, which are part of the gauge M, are bevelled upwardly in front of the cutting-die D, and are to insure the blanks taking their proper position.

The extent of the lateral feed is regulated by means of the screw G in connection with the slide F and the stop I, which is slotted into the gauge M and made adjustable by means of the screw M¹. Side gauging is taken care of entirely without adjustment, as this depends on the width of material which is being worked, and to get good results from dies of this description it is necessary that the width of material be uniform.

The eccentric X is to prevent withdrawal of the strip on the outward stroke of the slide. The arrangement of the pad P actuated by the soft rubber cushion Q was made necessary by the fact that the shell had to be slightly concaved on the bottom. If the shell had been flat, an ordinary push-through drawing die would have answered the purpose. The action of the pad P insures the fact that all of the shells will stick to the drawing punch T. This necessitates the addition of the stripper plate U, which travels on the stud V and is held upward by means of the spiral springs W. The travel of the ram of the press being more than the travel of the stripper-plate, continued upward movement of the punches insures the stripping of the shell from the punch, and the press being set on an incline, gravity causes the shell to fall back of the die.

The lubrication of the drawing die E must be done by a small tube (not shown) leading from left to right on to the drawing punch T, as the perfect working of this die depends upon keeping the shearing punches as dry as possible. A mixture of 9 parts soap-water and 1 part lard oil makes a good lubricant for drawing shell work.

The production of the die illustrated and described is 65,000 pieces per day of ten hours, and perhaps the best thing I could say about its method of construction would be that this particular die has produced, up to date, 9,300,000 pieces, without any perceptible wear, except, of course, to the drawing dies and punches; these parts must be renewed for every two or three hundred thousand pieces. The cutting and feeding parts after this enormous production show no great amount of wear. The question may be raised here, would it not pay to make a gang die and multiply the production at each stroke of the press? I am not in favour of multiple drawing dies, except in special cases, and I shall leave that question to be decided by the man who is responsible for the production.

* By GEO. B. PAINTER, in the *American Machinist.*

THE PREPARATION OF GROUND SECTIONS OF TEETH AND BONE.

FEW preparations for the microscope demand the painstaking attention to manipulative details that is required for the successful preparation of fine sections of teeth and bone. Many short notices have appeared in books and journals on rapid methods of making these sections by hand; rubbing them down on glass, stone, and in other ways. I have tried many of these, and do not find that I can get good results. To those who simply want one or only a few sections, I would say, you can get them from a dealer far cheaper than you can make them. To the student, or those who desire to make many sections, I offer the methods I use, to which I have drifted after large experience in making these preparation.

Apparatus.—A grinding machine, suitable laps of copper, lead, and stone, grinding powders, a chemist's wash-bottle, a small metal table, hardened balsam. My grinding machine is home-made. It is a large Swiss jeweller's lathe, fitted with a screw-chuck to carry laps, so arranged that the laps screw to a seat with great perfection. Above and parallel to lathe-spindle is a shaft in adjustable bearings; from this depends an arm or carrier, the face of which is arranged to receive and clamp with great accuracy cast-iron grinding blocks, about 3in. by 2in. by ¼in. in size. I use lead, copper, and "Scotch Water of Ayr" laps, which are turned true on this lathe. These laps, after turning, are ground one against another to *perfect* truth of surface. The grinding block, which when in the carrier can swing and be withdrawn from the lap, but is held truly parallel to the face of the lap, is now ground perfectly true to the lap. I use carborundum in four grades, from grains to that which requires fifteen minutes to settle. I grind with water from a chemist's wash-bottle. Use the grains on the lead lap, the powders on the copper, finish

with stone lap and water. The process can be divided into four heads: (1) preparation of material; (2) imbedding; (3) grinding; (4) mounting.

1. *Preparation of Material.*—(*a*) Teeth work best that are started "green"—i.e., that have never been allowed to dry out, for drying develops many small cracks, especially in the enamel. If the teeth need cleansing, wash them in dilute lye. Preserve in turpentine. Make rough sections with a ribbon or hack-saw. Make these sections thick, not less than one-sixth the length of the section, if possible. Where the saw cannot be used, grind away half of the tooth and make the section of the remaining one-half. True the surface roughly which is intended for the section. Wash carefully, picking out any grains of carborundum, and removing any soft tissues that it is not specially desirable to leave, as these are very apt to cause trouble. (*b*) Bones: Secure, if possible, fresh bone. Cut into short pieces, and macerate in water till all soft tissues are removed. Bone from the dissecting-hall, where subjects have been injected, is not well suited for this purpose, though, when well cleaned and selected, gives very good results. Saw the bone into rough sections as desired with the hack-saw, being careful that the thickness is never less than one-sixth the greatest dimension.

2. *Imbedding.*—The material, after being washed and cleansed of all grit and dust, is dehydrated in alcohol. For imbedding as well as for cementing the sections to grinding blocks, prepare some hard balsam. Take a commercial grade of balsam and dry it over a gentle heat till, when cold, it will receive the impression of the finger-nail under steady pressure, but flies to piece under shock. The material being dehydrated, pass it into chloroform; after a day add hard balsam from time to time for a week or ten days till the solution is syrupy, then pour off the solution and dry the material for a week or more, so that when cleaned of surplus balsam it shows no stickiness.

3. *Grinding.*—(*a*) Teeth: Clean away from the material all surplus balsam. Coat the surface of a grinding block with hard balsam. Arrange on this, section surface down, as many sections as can be placed on the surface, warm on the metal table, not to boiling, press each section carefully down in its place, cool, put into carrier, grind with coarse powder till a supporting surface is developed, supporting as nearly as possible the whole of each section surface. True this supporting surface accurately. Take a second grinding block, heat on the metal table, coat with balsam, remove to a wooden support, press into this softened balsam quickly and accurately, using only as much pressure as can be given with the hand, the supporting surface of sections. Before the sections can become heated through, plunge the whole into cold water; when thoroughly cold, wipe off and place on hot table with first block down. As soon as the water between the blocks begins to boil, slip block No. 1 quickly off and plunge block No. 2 with sections into cold water. Place the block into the carrier, grind with medium powder till the sections all show a surface suitable for finished sections. Polish the surface with finest powder, then with the stone lap, and finally with dry whiting powder and the hand. After polishing carefully, wash with water, being careful to remove all powder or grit of any kind, dry the surface carefully, and wipe the surface with the finger dipped into gasolene, using only the least possible quantity of gasolene. Clean block No. 1, heat it, and coat with balsam. Transfer the sections to block No. 1, as outlined above, being very careful to exert a uniform pressure in bringing the sections down on block No. 1. Grind first with the grains of carborundum, then, as the sections get thin, use finer and finer powder. If too coarse a grade of powder be used as the sections get thin, the enamel will be broken and the sections will leave the block. When all colour in the enamel begins to disappear, use the stone lap, then grind till all colour is gone from the enamel, the dentine looks transparent, not white, and the block seems to have only a coat of varnish on the surface. Polish with the palm of the hand and whiting, wash in water, dry, wash in gasolene, dry, immerse in benzole till the sections come away. (*b*) Bone is prepared in the same way, save that each section is roughly trued on one side before cementing to the block; they are then cemented with trued surface down, and the section surface is prepared directly, making only one transfer necessary in preparing the sections.

4. *Mounting.*—Tooth and bone sections may be mounted either dry or in balsam. If the cells do not suffer with a deposit of "dew," the dry mounts are the more permanent. The balsam mounts, if carefully made, will last in good condition for many years, and I think are much finer. I prepare cells for dry mounts with gelatine, and seal them with a fine ring of a hot thick solution of gelatine, finishing in black or colours, as desired. It is essential that the sections shall be perfectly dry, the cell dry, and both quite warm when the cell is closed. When made in this way I have lost few slides from "dewing." For balsam mounts I use paper-filtered balsam. Dry this on a slide, in large excess, till when cold it is nearly hard, but not flinty. While hot, coat with this one side of a suitable cover-glass, allow both to cool. Place the section between the two and press the cover down, using as little heat as possible. With a little practice and dexterity all the air bubbles that show up about the section will be washed away. Too much heat fills the section and ruins the mount. Cut away the excess of balsam, and wash, first with gasolene, then with soap and water.

As I have said, success depends upon *attention to details.* One grain of grit out of place at a critical moment will spoil all the sections. I have ground over 100 sections of small teeth on one block at one time. I usually grind 25 longitudinal sections of human teeth at once, and I have made sections of teeth 3in. in length and less than $\frac{1}{1200}$in. thick by this method. The same method can be used for any ground sections, applying, of course, suitable modifications—e.g., spines of Echinus, soft and hard tissues imbedded according to Von Koch or Weil, minerals, &c.—S. P. Cowardin, in the *Journal of Applied Microscopy.*

USEFUL AND SCIENTIFIC NOTES.

There are six new tunnel projects for Greater New York, not including the long-talked-of rapid transit railway tunnel lengthwise of Manhattan Island. Assuming the estimates of the projectors to be correct, the total cost of these six tunnels will reach eight million pounds. The various projects are as follows:—The Hudson River Tunnel Company, for a structure from Fifteenth-street, Jersey City, to near the foot of Moreton-street in Manhattan, the total cost of which will be more than 1¼ million pounds; the Manhattan Tunnel Railway Company, from Chambers-street and West Broadway to some point in Jersey City, to cost 1½ million pounds; the Manhattan and Jersey City Tunnel Company; the New York and Long Island Terminal Company, connected with the Long Island Railroad, for a tunnel from the Flatbush-avenue Station of the Long Island Railroad, in Brooklyn, to some point in Cortlandt-street, Manhattan, between Broadway and West-street, with a capital of £1,800,000; and the New York and Brooklyn Railway Company, which is planned to connect the city halls of the two boroughs, at a cost of not less than 1¼ million pounds. The three tunnels first named are to be under the North River, and the others under the East River.

Returns of Railway Accidents.—The Blue-book containing returns of accidents and casualties as reported to the Board of Trade by the several railway companies in the United Kingdom during the three months ended March 31 last, together with reports of the inspecting officers of the Railway Department of the Board of Trade upon certain accidents which were inquired into, has been issued. It appears that accidents to trains, rolling-stock, permanent way, &c., caused the death of five persons and injury to 157. All the persons killed were railway servants, and of the injured 117 were passengers and 40 were railway servants. The figures for the corresponding period of 1898 were 11 killed (eight passengers and three railway servants) and 87 injured (65 passengers and 22 railway servants). Of the five persons killed and 157 injured, 16 passengers and one servant were injured in collisions between passenger trains or parts of passenger trains; 72 passengers and two servants were injured in collisions between passenger trains and goods or mineral trains, light engines, or other moving vehicles; two servants were killed and 33 injured in collisions between goods trains, light engines, or other moving vehicles; four passengers were injured in collisions between trains and buffer-stops or vehicles at rest, caused by trains running into stations at too high a speed; 12 passengers and one servant were injured by collisons between trains and buffer-stops from causes other than the above; four passengers were injured by passenger trains of parts of passenger trains leaving the rails; three servants were killed by goods trains or parts of goods trains, light engines, &c., leaving the rails; seven passengers and two servants were injured by accidents arising from the failure of rolling-stock (wheels, tires, axles, &c.); one servant was injured by fire in a passenger carriage; and two passengers were injured in other accidents. There were 151 passengers killed and 378 injured in accidents from causes other than accidents to trains, rolling-stock, permanent way, &c., including accidents from their own want of caution or misconduct, accidents to persons passing over level crossings, trespassers, and others. There were also 113 servants of railway companies or contractors reported as having been killed and 1,101 injured, in addition to those already mentioned. Altogether the number of persons killed in the course of public traffic during the three months was 269, and the number injured was 1,635, the figures for the correspondig periods of 1898 being 270 killed and 1,406 injured. In addition to the above, 19 persons were killed and 2,816 injured upon the premises of railway companies in which the movement of vehicles used exclusively upon railways was not concerned.

SCIENTIFIC NEWS.

The "Rapport Annuel sur l'Etat de l'Observatoire de Paris" for the year 1898, by M. Loewy, the director, contains the usual information as to the work of the year, and is supplemented (or frontispieced) with a fine heliogravure of the moon, 20 days 5 hours old on Sept. 19, 1894, from a photograph obtained with the equatorial coudé of the Paris Observatory by MM. Loewy and Puiseux.

The *Bulletin* of the Société Astronomique de France for August contains an article by M. Camille Flammarion on "Le Monde de Jupiter," with several illustrations of the appearance of the planet as seen from Juvisy. It is an interesting paper for those who study Jupiter. Amongst the other articles, "La Rotation de Vénus," by the Abbé Th. Moreux, will be read with attention.

The *Journal* of the British Astronomical Association (Aug. 12) contains the reports of the branches in Australia, and of some of the observing sections. There are several interesting "papers," and a variety of notes which will be read with attention by students of astronomy.

Sir Edward Frankland, K.C.B., F.R.S., Ph.D. D.C.L., LL.D., M.D., &c., Government Analyst of the Metropolitan Water Supply, has died in Norway. He was born on Jan. 18, 1825, at Churchtown, near Lancaster, and was educated at the Grammar School of his native town, whence he proceeded to the Museum of Practical Geology, and completed his education at the Universities of Marburg and Giessen. In 1851 he was appointed Professor of Chemistry in the then recently-founded Owens College, Manchester (now the Victoria University). Six years later he was elected to the professorship of chemistry at Bartholomew's Hospital, and in 1862 he was appointed Professor of Chemistry to the Royal Institution. This post he resigned two years afterwards to accept the Professorship of the Royal College of Chemistry (School of Mines). Of the many publications from the pen of Sir Edward Frankland, the following are some of the most important:—Reports to the Local Government Board on "The Chemical and Bacteriological Condition of the Metropolitan Water Supply," "Lecture Notes for Chemical Students," "Experimental Researches in Pure, Applied, and Physical Chemistry," "The Source of Muscular Power," and "Water Analysis for Sanitary Purposes," and "Contributions to the Knowledge of the Manufacture of Gas." He was a corresponding member of the French and Vienna Academies of Science, Foreign Member of the Royal Academy of Sciences in Bavaria, and of the Academies of Science of Berlin and St. Petersburg; honorary member of the Societies of Natural Sciences of Switzerland and of Göttingen, of the Chemical Societies of Germany, and Lehigh University; and was honorary Foreign Secretary of the Royal Society.

The death is announced of Mr. John Cordeaux, of Great Cotes-house, Lincolnshire. He was born in 1831, and the ordinary occupations of a country life gave him the opportunity to compile a book on the birds of the Humber district, which is quoted by Yarrell as the authoritative work on the ornithology of that district. After the publication of this book he set to work to rouse the interest of coastguard men and lighthouse-keepers in bird life and migration, and in this way he organised a scheme for the scientific observation of the migratory habits of local birds and the occasional visits of strangers. A keen observer himself, and a successful stimulator of keenness in others, he studied as the main object of his life that which in others might have been only a hobby. He also took a lively interest in botany, archæology, and folk-lore, and was the first president of the Lincolnshire Naturalists' Union.

Mrs. Elizabeth Thompson, of Stamford, Connecticut, is dead. She was one of three "patrons" of the American Association for the Advancement of Science, and established the fund for scientific research which bears her name.

The Research Fellowships founded by the Salters' and Leathersellers' Companies respectively for the encouragement of higher research in chemistry in its relation to manufacture will be awarded probably before the end of the year. The grant made by each company is £150 per annum, and the Executive Committee of the City and Guilds of London Institute will, before the

commencement of the session, consider the applications and elect the candidates. Copies of the schemes under which the Fellowships will be awarded can be had on application to the hon. sec. of the City and Guilds Institute, Gresham College, Basinghall-street, E.C.

The German Naturforscher und Aerzte meets at Munich on Sept. 17-23, under the presidency of Prince Ludwig Ferdinand and of Duke Karl Theodore, the renowned oculist. These two princes of the Bavarian royal family have adopted medicine as a profession. It is stated that Dr. Nansen will lecture on his observations as a naturalist during his recent journey in the Arctic regions.

The monograph on the Atoll of Funaputi, which is to be issued under the auspices of the Royal Society's Coral Reef Committee, will not be published for some time, as the examination of the material will need special attention, and experts will have to express an opinion after examination of the borings. According to the *Athenæum*, there is enough material to make a volume of some 500 pages, if the geologists, botanists, and chemists are to report. It will be remembered that two expeditions have already supplied material for a tentative report; but the third expedition is probably the most important.

The report of the Geological Survey of the United Kingdom has been published recently, and shows that much work has been done in revising the maps on the 6in. scale. As to the results the Director-General draws special attention to the researches among the younger granites of the Highlands, particularly in the Cairngorm mountains and the Ben Cruachan group; to the numerous Cambrian fossils obtained in Skye; to the discovery of more new fishes in the Upper Silurian rocks of Lanark and Ayrshire; in addition to the remarkable series announced in the summary for 1897; to the evidence of the existence of volcanoes in Somerset belonging to the time of the Carboniferous Limestone; to the new light thrown on the structure and probable extension of the North Staffordshire coalfield; to the additional information obtained regarding the volcanic history of the western mainland of Scotland and the Inner Hebrides; and to the fresh data gathered from all parts of the three kingdoms with respect to the successive stages of the Ice Age. It is satisfactory to learn that the practical usefulness of the facts collected by the Survey and Museum of Practical Geology is becoming more widely recognised every year.

Preliminary arrangements have been in progress for some time in order that the National Physical Laboratory should be organised as soon as possible after the requisite funds were voted by Parliament. The six technical societies have nominated their representatives, the general board and executive committee have been constituted, and the greatest satisfaction will be felt at the announcement that Lord Rayleigh has accepted the chairmanship of these bodies. On the recommendation of the executive committee, the council of the Royal Society has appointed Mr. R. T. Glazebrook, F.R.S., now principal of University College, Liverpool, to the important post of director of the National Physical Laboratory. A number of sub-committees have also been organised by the executive committee, which have been requested to make suggestions preparatory to the drawing up of a detailed scheme of work and of the plans of the new buildings. The members of the executive committee are Lord Lister, P.R.S., Lord Rayleigh (chairman), Mr. A. B. Kempe, Treas. R.S., Prof. A. W. Rücker, Sec. R.S., and Sir Courtenay Boyle (*ex officio*), Captain W. de W. Abney, Sir N. Barnaby, Mr. G. Beilby, Sir E. H. Carbutt, Captain E. W. Creak, R.N., Prof. R. B. Clifton, Prof. G. C. Foster, Mr. F. Galton, Prof. O. J. Lodge, Sir A. Noble, Prof. J. Perry, Sir W. Roberts-Austen, Prof. A. Schuster, Mr. A. Siemens, General Sir R. Strachey, Prof. J. J. Thomson, Dr. T. E. Thorpe, and Sir J. Wolfe Barry.

In a memoir presented to the Paris Academy of Sciences, M. A. Chauveau states that the positive work done by the animal motor takes from the animal heat an amount quantitatively equal to the mechanical work done.

The following extraordinary paragraph has been published by the *Standard*:—"A Berlin engineer asserts that he has invented a new motor superior to any hitherto in use. It is, he declares, unlimited in its application, and may be used for carriages, waterworks of all kinds, and especially as a ship's propeller. One advantage claimed for the invention is that the apparatus is inclosed in a cylinder, and is not liable to external injury. Besides being more effective than the screw driven by steam, it is said to combine greater effectiveness with economy in construction, and at the same time to occupy smaller space. A trial made with a small model has, our Berlin correspondent says, proved, to some extent, the accuracy of the inventor's calculations, and a large model is now being made in order to test the value of the new system."

At the annual meeting of the Royal Botanical Society the sixtieth annual report was read, and disclosed a considerable improvement, at any rate in the number of members. The total number of Fellows and members was 2,102. The balance sheet to the end of 1898 showed a liability of £20,670 16s. 10d., which was more than covered by the amount of plant and buildings belonging to the society as a going concern. The report went on to say that, while increasing the refreshment-room accommodation, the council had sanctioned the establishment of a club within the society, which had proved a source of increased strength to the society, and had added greatly to the attractions of the gardens. The number of members of the club was now 560, including 220 ladies. The attendance at the gardens during the past twelve months reached 86,090, compared with 67,212 during the previous year. The chairman said the gardens were much more popular than they had been; but he would be very sorry to see their scientific character lost in that of amusement. The society was struggling on with too small an annual income; in fact, he did not think that the gardens could be kept up as they should be with the present low rate of subscriptions.

Liquid air is, it appears, to be used to hasten the process of eremacausis, and also to intensify the temperature of the crematorium. It is announced that a cemetery near New York is being equipped for the cremation of the dead in an electric furnace, supplied with oxygen by means of liquid air, thus reducing the process from hours to minutes.

Wireless telegraphy was tested during the recent naval manœuvres, and came out in a very satisfactory way; but it is now stated that wireless telephony has been tried by the Italian navy, and has been found to serve all useful purposes.

Signor d'Asar's wireless telephone, according to a correspondent of a morning paper at Rome, has been recently experimented with on a large scale at Spezia with excellent results. Messages were sent from the semaphore to ships at a distance of four miles, and warships were also able to communicate with one another just as if they had been connected by telephone wires. Admiral Bettolo, the Italian Minister of Marine, is said to be an enthusiastic admirer of the invention, and has given orders for its adoption throughout the Italian navy.

The latest discovery in America is a boy with such peculiar vision that he can see through substances in the same way as the Röntgen rays. His name is given as Afley Leonel Brett, of South Braintree, Mass. The boy is said to have diagnosed a number of fractures. In confirming the diagnosis of a broken hip he pointed out that the fracture was nearer the head of the bone than had been thought by the physicians. He examined a child who, it was supposed, had swallowed a coin, and declared there was no coin there. This was proved to be correct at the post-mortem, the child having died from other causes. The lad also uses this power by so concentrating the sight as to shut out ordinary daylight. The air, he says, is then filled with flashes of a pale greenish light, which illuminates the objects to be examined. This light, he says, is the same as the X-ray in the Crookes tube. Daylight is then darkness or a reddish black. Many wonders exist in America—especially during the slack season of the newspapers.

It is stated that the five-cent nickel coin of the U.S. currency was designed with special reference to its use as a unit of weight or measurement by the decimal system. It is exactly five grammes in weight and two centimètres in diameter. This is, of course, not an accident, and if there be any change in America's system of coinage, other convenient measurements and weights will be adopted according to the same system.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

THE GREGORIAN TELESCOPE.

[42684.]—In spite of some hard rubs from "H." (who evidently has but a poor opinion of "a certain Balolo") I will, with our Editor's permission, remind our able contributor that my letter on Compound Reflectors (41398), Aug. 26th, 1898, p. 40, was, on the whole, *a strong plea for the Gregorian.*

I will candidly admit that I, like many others, quite failed to see, *at that time*, the necessity for the accurate dimensions and measurements given by "H." But his exceedingly valuable series of articles on the Compound Reflector have been a revelation to me, and I think we must confess that readers of the "E. M." are greatly indebted to him for the pains he has taken to give a lucid account of a difficult subject.

I hope that his series of papers on Gregorian optics and construction may be republished in a separate form, as there is so much information therein not to be obtained anywhere else.

It was rather unkind of "H." to take no notice of my request that he would give me data for converting my short-focus Newtonian into a Gregorian! I did not feel this so much until I found out how much more gracious and complaisant he had been to Mr. "Ell Hay." And yet Mr. Hay is disappointing. For in 42669, p. 575, he says his Gregorian is no worse and no better than his Newtonian in definition, but most unpleasant in use! This is not what we want. How does his Gregorian perform on moon or planets? According to "H." the great virtue of the Gregorian lies in its power of forming correct images of objects having a sensible disc; and in this he assures us it is much superior to the dumpy Newtonian, although the latter may divide a close double star well enough. The method for finding practically the size and distance of "eyehole" *without the telescope*, as given by "H." last week, is very clever and ingenious. The *Edinburgh Encyclopædia* gives no account of the way to do this *with the telescope already made.* But that, as "H." says, is easy enough. Balolo.

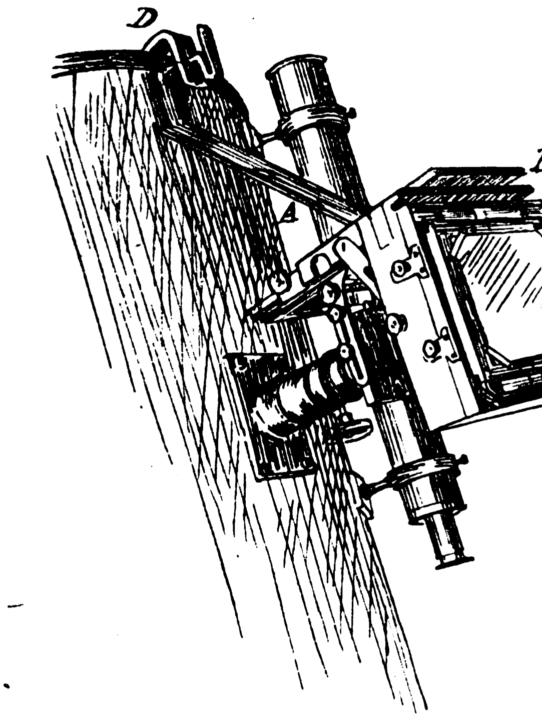
[42685.]—Being unwell, I can at present do no more than thank "H." for the details he gives of the two telescopes, and suggest to "Ell Hay" that a diagonal eyepiece will suit a Gregorian as it does a refractor, and that the former is no worse to use than the latter, as regards one's position.

A. S. L.

TELESCOPES.

[42686.]—It appears from various writers there is a good deal of trouble in getting secondhand telescopes. I have not had any trouble myself (of course, I am not a dealer); the reason is plain. I seldom take any reflectors but my own make, and I have every opportunity to overhaul, adjust, and try them before sending them out again; they are then equally reliable as new, and I am responsible. My second-hand ones are taken in when a client desires a different or larger instrument; they, therefore, do not get knocking about on the "market." I don't take a refractor before knowing or trying it; this course prevents disappointment. I have generally a list of those who are wanting such and such a thing when I "have one to offer."

Refractor makers, I believe, are also willing to take instruments and allow for them. But though the amateur knows he is quite safe in getting his second-hand instrument this way—some are fond of "bargains"—they sometimes, for a trifling difference, trust to what they call "picking up" one. The dealer buys many things in "the dark," or at sales; he is, therefore, as liable to be deceived as an amateur, and don't buy "lots" with the *intention* of deceiving; they don't find out their purchase till afterwards. They have not the opportunity to try them, and in the case of a reflector don't sufficiently understand them, so that an allowance must be made for a dealer. The dealer never buys only bargains; their expenses are great, and they must get a good profit. G. Calver.



THE NEWTONIAN REFLECTING TELESCOPE.

[42687.]—ADJUSTING LARGE MIRROR.—I do not know whether the following simple and certain method of adjustment has ever been tried or not; but I can certify that it admits of great accuracy. Point the telescope to sky, take eyepiece out, and fix a ½-plate camera, with its lens attached, in position as in sketch, and you will obtain, after focussing, a sharp image of large speculum, showing flat as a small round disc in centre. The three strips supporting flat mirror will also be shown. Now, with a pair of dividers, measure carefully the length of each strip, and if they are all equal the mirror is in adjustment; but if they are of unequal lengths, the mirror is, of course, out.

Fixing Camera to Tube.—As this plan of fixing a camera to a reflecting telescope is simple and efficient, and may prove useful to many, I will give details. The camera C, Lancaster's Instantograph, is fitted with a separate baseboard, B, with a long slot in centre. A is an iron strip suitably bent, one end of which is firmly clamped to telescope mount by means of clamp D, and the other end bent so as to be parallel with base-board. This end of the strip, which is slotted, is screwed on to base-board. When the focus is altered, the camera shifts up and down, and is clamped in position by means of its tripod-screw.

Barlow Lens.—I find that the definition of my telescope, the mirror of which is 12½in. aperture and 80in. focus, is greatly improved by using a Barlow in conjunction with the Huyghenian eye-pieces. Notwithstanding the great increase of power, I never now observe without the Barlow lens.

Cell.—It will, perhaps, be remembered that when I gave a description of my telescope in these columns a few years ago, some exception was taken to the employment of a disc of mahogany for cell-base, although it had been seasoned several years, and was well coated with shellac varnish. In order to see whether any improvement would result in the employment of a metal disc for mirror support, I had a disc of steel made some time ago, ¼in. thick, and both surfaces carefully levelled, that in contact with speculum back being made as perfect a plane as possible. Since this was done I have made many observations, but I cannot notice any perceptible improvement in definition resulting from the change.

Preserving Silver Film.—Since using a tight-fitting tin cap to cover mirror when not in use, I have had no trouble with silver film tarnishing, &c. I would recommend the rim of cap to be made of tin of a medium gauge.

Stellar Photography.—I use a ½-plate camera with wide-angle lens for taking the exposures, employing the telescope as a guide. My procedure is as follows:—The camera is screwed, by means of its tripod screw, on to a wooden saddle, which is firmly strapped to telescope tube. Both are now pointed to constellation which is to be photographed, matters being so arranged that the camera is focussed and adjusted for the star group whilst a fairly bright one occupies the centre of telescope field. Insert a medium power eyepiece and throw star out of focus; rack until there appears a large black disc surrounded by a bright ring. Uncover camera lens, and guide telescope so that the bright ring remains of the same thickness throughout the exposure. If it is desired to suspend the exposure for a time, the camera may be capped and exposure scope allowed to rest. On resumption, the telescope is again pointed to the star, and the the telecontinued. In case the equatorial mounting is out of adjustment, the declination clamp should be left loose, and the correction can easily be made whilst following the star.

Gateshead. T. D.

SOLAR EYE-SHADES FOR TELESCOPES.

[42688.]—WITH reference to the suggestion made by Mr. Ellison (in letter 42662) that the glass shade might be placed *within* the principal focus of the object-glass, instead of in the common place *on* the eyepiece. I may say that I use a $2\frac{7}{10}$in. achromatic by Ross, in which I have the coloured glass shades fixed in short brass tubes which fit into the several eyepieces of the telescope on their further side (that is, on the object-glass side of the eyepiece). With my instrument I find this plan to answer admirably, and the definition is excellent. With a large aperture I should doubt whether the heat would be sufficiently lessened at this position, but the place of the screen glass might be put still further within the focus.

Some years ago I used a 3½in. achromatic with diagonal solar tube, having a glass plane reflecting surface. With this I found that although the glass shade-glasses were not cracked, yet after a time they were spoiled by the appearance in their centres of a small swelling or pimple, the result apparently of partial fusion. Excepting perhaps with very small hand-glasses, I do not believe that it is safe to use a dark glass over the eyepiece in the usual way, although most 3in. advertised astronomical telescopes are sent out with them.

15, German-place, Brighton. R. J. Ryle.

RELATIVE AMOUNT OF ABERRATION IN COMPOUND REFLECTORS — LEARNERS AS AUTHORITIES.

[42689.]—I BEG to thank your skilled and courteous contributor, "A. S. L." for his kind appreciation of my attempt to illustrate, in letter 42620, the possibilities and conditions of aberration corrections in the Gregorian telescope, with casual reference to the Cassegrainian. I am sure we all heartily wish him many more years in which to exercise his keen but just criticisms of whatever relates to subjects of this kind, and, to our benefit in the past, we know his abilities have by no means been limited in "Ours" to this narrow scope.

The present note is given with the intention of deferentially adding to, not detracting from, his remarks on the subject mentioned above, and referred to by him in letter 42649. I am constrained the more to do so, as I feel certain that many readers who interest themselves in these matters, but who may happen to be less posted in optical science than your able correspondent, will be very apt to draw reversed conclusions from the comparison he gives, when he says, "The total amount of aberration to be dealt with is far greater in the former (the Gregorian) than in the latter (the Cassegrainian), and this seems to more than restore the balance in favour of the Cassegrainian."

In so short a note as 42649 the omission of many points was a necessity, and his omission to say that the above "balance in favour of the Cassegrainian" could only refer to the primitive form of compound reflectors of the early writers and of the textbooks—i.e., with *spherical specula* (for until recently no other curves were deemed possible), has drawn from me this addition to his remarks. This addition I humbly submit, with the hope that neither the able author whose letter I annotate, nor the general reader, will attribute to me the smallest wish to place the slightest discredit upon the communication of so valued a fellow-contributor: a contributor who, well versed in theory and of long practical experience, has never been found, like some recent would-be practical critics, attempting to pronounce with assumed "practical" authority upon the merits or demerits of arrangements the nature of which (to judge by requests just made for very elementary information) time alone has not as yet permitted them to learn beyond the merest rude elements, either as a science or an art.

And yet this critic would have us take crude experimental results, made withal, upon a vitiated basis, as authoritative dicta upon what, in well-instructed and experienced hands, has long been known to the contrary! (See "Hay" on Alteration of Newtonian, 42669.) Far different are "A. S. L.'s" remarks, and when I differ from him, as I on a few occasions have done, I feel that I am differing from one whose experience is worthy of respect in every way.

In making comparisons as to relative amount of aberration in Gregorians and Cassegrainians, let us separate the conclusions thus:—

(1) Let both telescopes have spherical curves throughout. Here there can be no doubt about the spherical aberration being somewhat (not "far") greater in the Gregorian than in the Cassegrainian, in which latter, if only the specula could be made more nearly equal in focal length than practice allows of, that aberration might be almost altogether eliminated—a Utopian condition only but faintly approachable in the very smallest sizes, where F : F' may be made as low as 4 : 1.

(2) Consider, now, both telescopes to have such figures on their specula as have already been stated, and long known to be theoretically capable in their combination of correcting this *spherical aberration*, the only really great aberration from which any form of reflecting telescope can possibly suffer, leaving out of consideration for the present the so-called Schaeberlean error entirely. With properly matched conics, we have just seen (42620) how the Gregorian may be made to have no remaining trace (theoretically) of *this spherical aberration*—i.e., the Gregorian becomes "aplanatic" in the sense in which English optical writers use that term, "flatness of field" remaining quite another consideration. That flatness has, however, also been shown to be equally attainable in the fully corrected Gregorian, and by the same means used to correct the error of sphericity. Also we have seen how, under similar geometrical conditions, with suitable curves for the Cassegrainian, spherical aberration also vanishes, but we are not to forget that *this correction is not one whit more easily effected or more perfectly attained in the Cassegrainian*, because it so happened that with spherical specula it was on the way, so to speak, towards that correction already.

Once leave spherical figures, and the convex small speculum becomes no longer an advantage in the least, as the parabola and hyperbola of the Cassegrainian come no nearer an aplanatic combination than do the parabola and the ellipse (or other curves) in the case of the Gregorian. Indeed, as already noticed by all practical men, the Cassegrainian cannot to the same extent as the Gregorian take advantage of the above *theoretical equality* in spherical aberration correction by reason of the almost insurmountable difficulty of figuring a true *convex* hyperboloid.

But suppose that difficulty overcome, the two telescopes are still but equal in above corrections, neither having the slightest advantage ("in that respect"). With even spherical specula (attempted) the same trouble supervenes, and hence the old writers, while noticing the slight theoretical advantage of the Cassegrainian, were careful also to mention the fact that practice by no means realised these expectations. (See Smith, Coddington, Barlow, &c.)

(3) In flatness of field, as in corrected spherical aberration, both types, by the use of properly-matched curves, are theoretically in perfect equality.

(4) The so-called Schaeberlean error, or error depending upon inequality of magnification in different zones of the image, can also, as we have seen, be fully got rid of in the Gregorian. In the Cassegrainian, instead of this correction, we have the error in question somewhat exaggerated.

(5) The final balance between the two compound reflectors, *when conic section curves are taken advantage of*, stands thus:—

(*a*) Spherical aberration (the major error) equally corrected in both.

(*b*) Curvature of field equally corrected in both.

(*c*) Zonal equality of magnification attainable in the Gregorian, *not so* in the Cassegrainian.

Therefore the last-mentioned error, plus the more probable greater departure from theory in the figure of the small speculum, remains against the Cassegrainian, "*leaving the balance in favour of the Gregorian,*" the reversed placing of the advantage being only possible on the old lines with spherical specula, and in this, modern practice has corroborated theory.

H.

THE PERSEIDS 1899.—I.

[42690.]—Watch was kept for meteors on August 10th, from 10h. 35m. to 15h. 0m. During this period the sky was wholly clear except from 11h. 0m. to 11h. 10m., the time of actual observation being, therefore, 4h. 15m.

A meteor as bright as Jupiter was seen by my brother about 10h. It fell from near β Ursæ Minoris through Boötes—a more exact position cannot be given. There was a slight streak.

From 10h. 35m. to 11h. 0m. the hourly rate of meteors was 14; from 11h. 10m. to 12h. 0m., 13; from 12h. 0m. to 13h. 0m., 21; from 13h. 0m. to 14h. 0m., 27; from 14h. 0m. to 15h. 0m., 21. No allowance has been made for the time occupied in recording.

Details of the whole of the meteors appear in the above table, from which I obtain the following radiants:—

Meteors.

A. 5° + 50° (5, 10, 14, 34, 54, 58).

B. 43 + 57½ (1, 2, 7-9, 11, 13, 15, 16, 18, 19, 21, 22, 24, 25, 28, 30, 32, 33, 36, 40, 43, 44, 46, 47, 50, 53, 56, 62, 64, 66, 70, 72, 76-79, 81).

C. 47½ + 59 (23, 26, 27, 31, 35, 38, 41, 42, 45, 57, 59, 63, 65, 67, 71, 85).

D. 64 + 34 (29, 49, 68, 80, 82, 83, 86).

E. 340 − 5 (48, 52, 55, 69).

The remaining table classifies the meteors according to their magnitudes against the several radiants:—

Magnitudes.

Radiants.	= ♃	1st.	2nd.	3rd.	4th.	Totals.
A	—	—	—	4	2	6
B	3	6	18	7	4	38
C	—	3	7	6	—	16
D	—	—	3	2	2	7
E	—	—	—	3	1	4
—	1	—	2	5	7	15
Totals..	4	9	30	27	16	86

Further observations are reserved until next week.

Walter E. Besley.

The Chase, Clapham Common, Aug. 12.

[42691.]—The Perseids were well seen here. On the night of the 10th I counted 37 between 9 and 9.45 Paris time. I could only see clear to the horizon on the North. Three struck me as exceptionally brilliant, one at 9.8 passing through the square of Ursa Major being fully equal to Vega, but leaving no trail that I could see. Another passed through Corona Borealis at 9.24, leaving bright trail of a greenish colour. At 9.48 one passed close to Arcturus. I just caught it with an opera-glass, and the trail appeared like small sparks. All seemed to radiate from close to Perseus.

Boulogne-sur-Mer. Verinder.

THE DELUGE.

[42692.]—Letters upon this subject have lately appeared in your pages—for you are good enough to insert most of the communications from your subscribers—but, when they relate to the above subject, do we advance much? The facts seem to me to stand this way: In years gone by, certain priests wrote that which they, with their limited knowledge, thought interesting and possible; this has been handed down, but how few men who think can accept a word of it as true.

In the first case, geologists show clearly that there have been many floods; they probably arise from the earth's motion relatively to the sun. There is about twenty-two thousand years between flood and flood. This being so, how many hundred years must have passed between the building of the Ark and its being floated.

Then as to its size and its capacity. Well, it it must have been less than some of our modern vessels. Now, will any one venture to say that the largest of our vessels is approaching the necessary size to hold two of each kind of animal and its food. The thing is preposterous.

Next comes the floating. Can anyone suppose any vessel to be strong enough (even if built of our present high-class steel) to withstand the floating and the stranding. We surely have enough everyday experience to show that to touch ground means destruction of the vessel.

It may be said that Divine power influenced and made the Ark an exception to the action of natural law. But if this supernatural power were introduced, it seems to me that animals and men would have been left to float about under its protection in the fresh seawater. It would be far better than being crowded together in a filthy box. J. W.

[42693.]—There is a serious objection to the line of argument Mr. Rouse (letter 42665) adopts. A tradition, to be accepted as evidence of the occurrence of an event, must not be contradicted by facts. I sing of facts, as Ovid says, and no one accuses geologists, anthropologists, philologists, zoologists, and archæologists of inventing the awful array of facts which confront the tradition of a universal Deluge. Jesuit and other missionaries have travelled far and wide, and in some cases an apparent diluvial tradition may be but a relic of their teaching. However, local inundations (such as that of the Yang-tse-Kiang) naturally make us expect diluvial myths in various localities.

Lenormant and others have tried at various times to deduce Chinese characters from Cuneiform without any very great success. But if we are to suppose the Mongolian progenitors emigrated from Armenia a few thousand years ago, it is difficult to see why they took with them the contemporary

writing, but not a ghost of the language or grammar, Chinese being radically different from any of the so-called Aryan languages. It seems better to credit the Chinese with the independent invention of a method of writing. If one traces both methods back to the simple pictorial representation of objects, any discoverable similarity becomes easily explicable. I may add that these attempted identifications were generally to support a theory that Central Asia was the locality from which the human races dispersed. It has since been shown that there is no solid basis for the hypothesis.

As for our Diluvian sophist (letter 42667), Genesis vii. 21-23 are too explicit to support his quibbles. To imagine that Plutarch describes a Noah's Ark at Thebes is just as comical as to conceive a philanthropical partnership between Rameses the Great and his much-beflogged fellaheen. Mr. Garbett omits to mention why, if the extinct animals he names were alive in B C. 3102 (his date), pairs of them were not preserved in the Ark. For all the rest of the animal kingdom to merit drowning there must have been a shocking amount of depravity amongst the poor beasts. One supposes the monstrous turpitude of the rabbit equalled the notorious vice of the humming-bird, and the abandoned shamelessness of the slug, the gross moral delinquency of the gazelle. Such odd reflections make it difficult to discuss a recent universal Deluge with becoming gravity. J. Dormer.

PROFESSOR BONNEY'S STORY.

[42694.]—THE "Fellow of the R.A.S.," on p. 576, refers "Glatton" to Prof. Bonney's "Story of Our Planet;" but does he mean the Rev. Professor's *Sunday* or *Monday* story of our planet? because these are widely divergent. On some Sundays he teaches "As it came to pass in the days of Noah, even so shall it be also in the days of the Son of Man. They ate, they drank, they married, they were given in marriage, until the day that Noah entered into the ark, and the Flood came and took them all away." Moreover, he gets £1,000 a year indisputably for this doctrine of the "Story of Our Planet," but possibly nothing, or less than nothing, for the different story that he has compiled. I would advise "Glatton" to keep to what brings the Professor his £1,000 a year, and save even the price of the book that the "F.R.A.S." recommends.

E. L. Garbett.

WIRELESS TELEGRAPHY.

[42695.]—STILL another system of communication between two distant stations by means of Hertzian waves has lately been devised by Prof. Braun, of the Strasburg University, said to be quite different from Marconi's, and that of the Buda Pest firm of Shaefer and Co. The inventor and his assistant, Dr. Canto, of the same university, have been experimenting for some time under the auspices of a syndicate, of which Herr Zole-Koeln, banker, is chairman, and G. W. Bargmann, Hamburg, Manila merchant, one of the leading members.

On the 13th July last a practical demonstration of the merits of this new means of communication between two distant stations was given before the finance committee and a number of invited guests, which turned out very satisfactory. The messages were sent by means of an ordinary Morse writing telegraph, which has long been in use on a *wire line* from the Cuxhaven lighthouse, or rather a temporary wood erection near it, to the well-known *Kugelbaake-Helgoland*, four kilomètres off.

After a short address by Dr. Cantor, in which he accentuated the reliability of their process, and the hope that they might soon succeed with even simpler apparatus, the practical test was given. The audience waited in great suspense the answer to the transmitted message from the receiving station.

In due time the bell rang, and the clicks of the Morse instrument were heard, though a rising thunderstorm somewhat interfered with their regularity, as they are with the ordinary wire line connections of telegraphs and telephones. Wind and rain seem to have no impeding effect. On the whole the audience was satisfied that a step forward had been made in this wireless telegraphy.

A. Caplatzi.

REDUCING INTENSITY OF LIGHT.

[42696.]—MR. ELLISON (letter 42662) may probably obtain what he requires from Messrs. Horne and Thornthwaite, of the Strand, who some years ago introduced Levander's solar and sidereal diaphragm eyepiece. The instrument takes the place of the ordinary draw-tube, and therefore slides into the body of the telescope, and may carry the fitting of a Barlow lens or of a dark glass at its further end. The other end carries a draw-tube to receive any eyepiece, while midway is a diaphragm, the aperture of which can be varied by a screw having an external milled head. A description of the instrument will be found in the *Monthly Notices* of the R.A.S., XXXIX. 199. U.

UP "DEVONIAN," G.W.R.

[42697.]—THINKING it might interest many of our readers, I give below times I took of a run in the new train running this summer from Exeter to London, a distance of 194 miles, without a stop. The train is allowed 3 hours 50 minutes for the journey. Both the driver Warren and the stoker Richards deserve credit for the way in which the pace was evenly maintained throughout the entire journey. Date, July 19, 1899; Engine, 7ft. 8½in. single bogie Wellington, 3028; train, six eight-wheeled coaches (five corridor) equal 155 tons behind the tender; weather fine, dry, and calm.

Dalays: Checked to 15m.h. at Cullompton, and also to 5m.h. at Brent Knoll, with a slow to Worle Junction, besides the regular slows at Taunton, Bristol loop, Bath, Chippenham, Didcot, and Reading. Total time lost was 19m. 30s.

Booked time for journey, 230m.; speed, 50·6m. h.; actual time for journey, 227½m.; speed, 51·2m. h.; net time for journey, 208m.; speed, 56 0m. h.

Flying average: Bradninch to Acton, 181 miles 25 chains in 189m. 36s.; net time = 57·4 miles an hour.

Maximum speed was 82 miles an hour near Wellington. The running of this train reflects great credit on the company.

Ealing. O. R. Walkey.

IMITATION IVORY KNIFE-HANDLES.

[42698.]—LET me warn housekeepers and others against buying the imitation ivory knife-handles and other articles now becoming so common.

Last Tuesday week at the house of Mr. Bettle, confectioner, Market-hill, Woodbridge, Suffolk, a table-knife was lying on a table about 6in. from a gas-stove which was alight. Suddenly Mrs. Bettle was alarmed by seeing a sudden flash of light and a quantity of smoke, and discovered that the handle of the knife, which was made of some composition in imitation of ivory, was ablaze, and in a few seconds nothing remained of the handle but powder. Many fires are probably thus caused. E. S.

FLYING CRAFT MADE PERFECT.

[42699.]—IT is evident T. May (letter 42675) has not studied the subject of mechanical flight to any very great extent, or he would know that the very identical plan he suggests was the first ever tried. Quite naturally, men at first thought that flying the air could only be accomplished by means of a pair of wings shaped like those of the bird, and supplied with motive power from within the machine as near like the bird supplies the force as possible. Let me assure T. May that this is a very old plan, and a very useless one to boot. Just as well might George Stephenson have studied the anatomy of the horse, and then proceeded to construct a machine that should imitate it. Would he have succeeded? Well, he had just the task before him, in connection with the land, that we have before us now in connection with the air—ours is a trifle more difficult by reason that there is nothing stable in the air on which we may plant our machine. Barring this one fact, there is no difference between Stephenson's task and ours, that I can see, and I venture to say: Just as he succeeded, after overcoming any amount of opposition and ridicule, so shall we, in like manner, succeed, and our success will, in the course of time, be more effective and more complete in every way than has been Stephenson's, great and wonderful as that has been. For, remember this: the world cannot possibly stand still; it must advance as long as it exists, and once in the air, there can be no more changing about; once in the air, man will never come back to the land and sea. There will be two reasons for this—first, to do so would be to go backward, a thing man never does; onward is the grand order, and we cannot disobey it. The second reason is, when once we have a machine that will carry us safely through the air without dirt, dust, and noise, we shall think of beginning to get back some of the room and some of the land that the iron horse has robbed us of all over the world. Just fancy the number of acres in fertile little England that is taken up by railways, and what might not be grown thereon; but we are not going to fly the air by trying to do the impossible, as T. May suggests. We must use our own intellect to some purpose, because we have to discover at what points we can follow nature, and where, as I have already said, we must leave the paths of nature and strike out for ourselves. When once we can fairly see this, the work is accomplished—we have only to form the machine, and, of course, that will be no more difficult than it is now to form a locomotive engine or a steamship. I should like to respectfully inform "Desmond" that I have got a little beyond mere theory. I have been in a position to construct a practical flying machine on the lines I roughly sketched out in my letter of August 4, for the last four years. At any time during those four years of precious time I could have formed into shape that which I feel certain will be in years to come the universal carriage of the air. The fairy road through the air is the grand highway that is to be. Of this I am as certain as that the sun will rise to-morrow morning. But to go back to T. May's contention—namely, that our only chance is to imitate nature in form as well as principle. It was because they clearly foresaw the utter fallacy of attempting such a ridiculous plan that induced Mr. Maxim, Prof. Langley, and many others to go to the other extreme, and try to fly the air in a different way altogether to that which the bird practises—namely, to fly without wings. This, as far as actual flying goes, is a great advance on the utterly impossible gigantic-bird theory, and Mr. Maxim most assuredly would have succeeded in not only crossing the Channel as he promised, a few years ago, but in all probability would, ere now, have crossed the Atlantic, also in the air, for he demonstrated the possibility of mechanical flight at Bexley Park beyond the shadow of a doubt; in fact, his machine had such a lifting power that it actually tore or forced up one of the guard rails that was intended to keep the machine from flying away into the air, as it would have done had not these rails been placed over the wheels to prevent it doing so; but the one great drawback to the aëroplane is the terrible fact that no machine built on this plan can ever be one single moment safe in the air. Now, the true and only practical plan, as I have already said, and as I am prepared at any time to prove, lies just midway between these two utterly

impossible plans—one impossible, because it follows nature too close, the other impossible because it does not follow nature at all. The true flying machine will do the work on the same principle that the bird does, but in quite a different manner. As regards "Desmond's" remarks as to the speed of the wings of gnats versus swallows, and so forth, let me point out that this is, after all, pretty much a case of figures. Let "Desmond" take for his standard, say, a swallow. Now imagine a bird, made on the same lines as the swallow, but only just half the size. This will be rather difficult, as every bird is built on slightly different lines to any other. However, we will imagine a bird exactly half the size and weight of the swallow, but otherwise just like it. This bird would of a necessity flap its wings twice to the other's once; but the points of the wings in each case would travel exactly the same speed. Now, imagine half the size of the smallest, and the wings would make four strokes to one of the other, and yet travel at the same speed, so that if "Desmond" can get at the exact length of the gnat's wings, he will get the knowledge he asks.

Thomas George Challis.

FLYING CRAFT MADE PERFECT.

[42700.]—In my letter on p. 558 I entirely forgot to mention one very interesting fact in connection with the working of the bird's wings when in the act of flight. This is the extremely interesting fact that the wings descend more sharply than they ascend. Years ago I was very much puzzled why the wing of the bird did not draw the bird downward with as much force, or more, that it pushed or drove it upward, seeing that by the shape of the wing—viz., concave or hollow the underside, there naturally would be a greater partial vacuum under the bird than there would be above it, just the place where the greatest vacuum was wanted. The explanation of this apparent mystery is this extremely interesting fact: The bird, as I have already said, drives the wing down more swiftly than it lifts it up; thus we see this singular fact that the wing is really longer going up than going down; this causes the amount of vacuum created on either side of the wing to be just equal notwithstanding the difference in shape. This fact places vacuum out of the whole operation altogether. As far as the act of flying is concerned, vacuum neither helps nor retards the bird, but is exactly balanced. This proves again that all flying things get the power to fly in the air under any possible condition—windy, calm, dead still, or any condition in fact. Anywhere where there is air the bird can raise himself up in the air and go forward though it, and let us make no further mistake at this point. This power to rise and go forward in the air is all got by simply beating or striking the air harder and more effectively with the underside of the wing than with the top, and to do this the bird has to do as E. Wilson suggests, draw or contract the wing on the up stroke and expand it on the down stroke in order to first take a greater surface of air, by reason of the expansion, and, second, strike the air harder by reason of the fact above mentioned—namely, the wing descending sharper than ascending. This explains everything. There is no mystery anywhere, though men of science, that know very little of mechanics, have at one time and another manufactured almost any amount of mystery concerning this really plain and simple feat of flying the air. Edgar Wilson, writing in a recent number of the "E.M.," says that Lilienthal could perhaps have recovered himself when taken by a sudden gust of wind had his apparatus been differently made; but, with all respect to Mr. Wilson, this is a mistake. No machine with large, flat, or, worse still, concave, surfaces, will ever be safe in the air one single moment. It is impossible. Such machines will be at mercy of every gust of wind that may in any instant spring up, and sooner or later they must be destroyed, that is if they ever get far enough from mother earth. This is the reason why I have suggested to Prof. Langley that it is not improvement, but a thorough new principle on which to design his machine. In the machine of my design the car will be the largest surface contained in the whole machine, and that will be round so that the wind will glance off all sides; but allow me to say that, though apparently so dangerous to those not well versed in the subject, the navigation of the air will, there is every reason to believe, be the safest mode of travel ever devised by man, and there are several reasons I would give for this. However, there is not space here to go into these reasons. I may say this much, however, it would be quite possible for two flying machines to meet in collision in mid-air, and not a single life be lost thereby. Every flying machine will act as a parachute should the engines stop working.

Thomas George Challis.

[42701.]—I should like to make a few remarks respecting this subject. I have studied the problem of aërial flight for a good number of years, and, although my experiments connected therewith have been upon a very modest scale, they lead me to the conclusion that Mr. Maxim and Dr. Pettigrew are, with respect to the particular systems which they have openly advocated, both right. In my opinion, a successful flying-machine could, as far as elevating and propelling are concerned, be made upon three different systems—viz., the aëroplane with screw propeller for driving; the rotating screw propeller upon a vertical axis for lifting, with similar means upon a horizontal axis for driving; and the feathering wing for both lifting and driving. The present difficulty in these days of light powerful engines and potential energy stored in small compass is not so much that of lifting and driving as that of maintaining the equilibrium in the air. The flying-machine of the future will be a heavy body, having very powerful light engines and high-speed motion, and capable of great speed in travelling. A light body having a slow motion would be useless, practically speaking, as it would be at the mercy of the wind. There will be no balloons or aërostats in connection therewith.

The experiments I have made with wings strongly convince me that the figure of 8 theory of Dr. Pettigrew respecting wings properly applied is the only wing theory likely to meet with success. One has only to construct a wing upon and use it in accordance with Dr. Pettigrew's system to convince oneself of its enormous lifting and propelling power. I am strongly of opinion that Dr. Pettigrew has discovered the true actions of birds' and insects' wings.

Many birds contract the wing during its ascent, which, together with its peculiar formation, causes it to offer less resistance to the air upon its upward movement; but the upward and forward motion of the bird is, without doubt, due to the "feathering" effect of the wings.

I quite agree with the remarks of Mr. F. H. Wenham in your issue of the 28th ultimo.

Liverpool, August 8. R. J. Urquhart, C.E.

[42702.]—I trust you will permit me to enter the arena of discussion now going on the subject of flying, &c., in order to point out several erroneous statements—viz., the limiting to *one way only* of attaining certain results, when there are numerous ways and mechanical methods of accomplishing the same end; also to endeavour to defend Dr. Pettigrew's theory, figure of 8 line, to some extent practically demonstrated by me before a meeting of the Aëronautical Society of G.B., 1870. I will first take the statement relating to the flexure of wings of birds, "the pivot on which the whole problem turns." Surely Mr. Challis does not mean to assert that the flexure of wing, including reductions of superficial area, is the only process by which flight is attainable: it only applies to birds, the Chiropterea, and a few other species. Nearly all the other species have a different method of leaving and rising from the ground. Mr. Maxim never meant the construction of a machine to fly like a bird, but simply to prove the great power and lightness of his engines and the efficiency of the fixed aëroplane principle, which still remains undecided. "We may remain behind Nature except in lifting power. . . This great lifting power is to be attained by the process of the flexure up of the wings, and deflexure down of the same wings. We are doubtless much behind Nature at present, both in lifting and travelling. Mr. C. will be satisfied to travel at five miles an hour. I feel sure that nobody else will be, after describing his peculiar screw, and placing it in front to draw the whole machine. This is the only way of steering." I fail to understand that if the flexed process is so highly efficient, why the combination with the screw does not make a purely flying machine or a purely screwing one. The fact is, there are many different methods of steering. A bird that has lost his tail does not appear to affect his steering qualities much. His wings are like a pair of scales turned upside-down, but are in this case far more sensitive to the least pressure accelerated by velocity than our very best adjusted scales are affected by a few grains. The body of the bird being the fulcrum feels the least disturbance or difference of pressure, and at once instinctively re-establishes the balance either by a slight muscular tension or angular alteration, or a reduction of the superficial area of the opposite wing. Mr. C.'s large machines, I take it, viewed from under, will resemble a flock of birds flying in a line, or a series of lines, from a few yards to several miles long, and we can safely assume that the longer the line the greater will be the range of safety for balancing. Then comes the assertion that man can never fly. Will Mr. C. kindly prove by figures the truth of his statement? and, again, "by gravitation *alone* can we obtain safety." With a motor sufficiently powerful we may to some extent disregard gravitation, as in case of a projectile, the extension of length and breadth, the combination of machine and balloon as to the shape, &c. The fact is, the shape or form of the machine is no more limited than the numerous forms we find in nature. If there is anything "childish," it can only be Mr. C.'s remarks on Dr. Pettigrew's theory of the figure 8. Dr. Pettigrew recorded the fact that the locomotive extremities of most of the animals (birds, fishes, and insects included) describe a more or less perfect figure of 8, modified or amplified by the various motions and rates of travelling of the respective animals, and generalised the theory more as a means to an end, and not as a basis from which a machine should be constructed. Mr. Sutcliffe is more generous, and frankly accepts the theory up to a certain rate limit. How does Mr. S. arrive at this limit? It seems to me that, all things properly and rightly proportioned, there can be no such limit. I may add the engineers of the future may compute the efficiency of the active surfaces of aërial machines by their dynamic tracings or indicator diagrams of the respective surfaces. Mr. S. makes the assertion that birds that fold their wings entirely after each projection do not weigh more than 2oz. Mr. S. can only mean the sparrow class; but the fact is that the woodpecker class weigh several times 2oz; they fly on the same style as the sparrow. If I have succeeded in widening the scope of investigation, and in logically proving that there are, *not one*, but many ways by which the same results can be attained, the object of this note will also be conclusive.

Louis Senecal.

[Previous discussions on this subject have usually degenerated into mere word-wrangles. We do not mean that this shall, and warn correspondents that if they have nothing new to say, they need not trouble themselves merely to write attacking other correspondents, as their letters will not appear. —Ed.]

A "FLY" PROBLEM AND ANOTHER.

[42703.]—I would suggest the best way of answering this problem is to take the second question first. Imagine the fly, therefore, to have alighted on the carriage. Clearly, I think, the load will have been increased by the weight of the fly; but at the same time relieved of the weight of an equal bulk of air displaced by the fly. That is to say, the actual increase in the load will be the weight of the fly weighed in a vacuum less twice the weight of an equal bulk of air. Now, imagine the fly exactly poised in mid-air, the load will remain the same as before, for the upward thrust of the wings is just equal to the downward pull of gravity, and this thrust will be transmitted through the air to the body of the carriage, and thence to the axle. If, however, the fly commences to rise, the load, it appears to me, will increase in proportion to the additional thrust exerted by the wings, less, however, the amount required to overcome the resistance of the air; whilst, again, if the fly were to fall without effort, there would be no additional weight on the axle at all during the second or two it was falling; save, again, a small quantity due to the resistance of the air. Thinking over this problem brought a train of ideas which have ultimately taken shape as another somewhat similar problem, on the solution of which I should much like to hear the opinions of some of "ours." Imagine an iron cylinder hermetically sealed and exhausted to an absolute vacuum; at one end a pistol-barrel containing a spring and a bullet. At the centre of the earth is a cave, likewise hermetically sealed and exhausted, and within this cave is the cylinder, hanging, of course, in space, like Mohammed's coffin. All being at rest, the spring is automatically released, driving the bullet against the opposite end of the cylinder. What will be the effect upon the cylinder? W. J. G. F.

THE FUTURE OF AERIAL LOCOMOTION.

[42704.]—My warmest thanks are due to Mr. Challis and G. Sutcliffe. I am pleased to see that my opinion of the flexion and extension of the bird's pinions coincides with other fellow subscribers of the English Mechanic. There is also another point I wish to point out, and that is—in all wings, whether natural or artificial properly constructed ones, when the wing is elevated in the upstroke the outer half of the pinion darts forward; contrarily, when it is depressed in the downstroke it is impelled backward, a result which is entirely independent of the flexion and expansion of the wings. This last is caused by the great elevator and depressor muscles of the bird in conjunction with smaller ones exercising a restraining influence on the wing when it is beaten. In other words, the muscles are elastic ligaments, to enable the wing when forcibly depressed to restrain and moderate the force of the beat when desired, and to allow it to spring back again easily. Now, when I say the outer half darts forward, I do not mean that the inner half remains rigid; on the other hand, the whole wing itself darts forward when beaten, the outer half or tip extending more so. It is essentially a forward movement when in motion—a fact due to the anterior or front margin of the wing being semi-rigid and thicker than the rear margin—posterior—comprising the feathers. Therefore Mr. Challis will pardon me if I persist in adhering to my first statement that, on the foregoing basis, individual flight

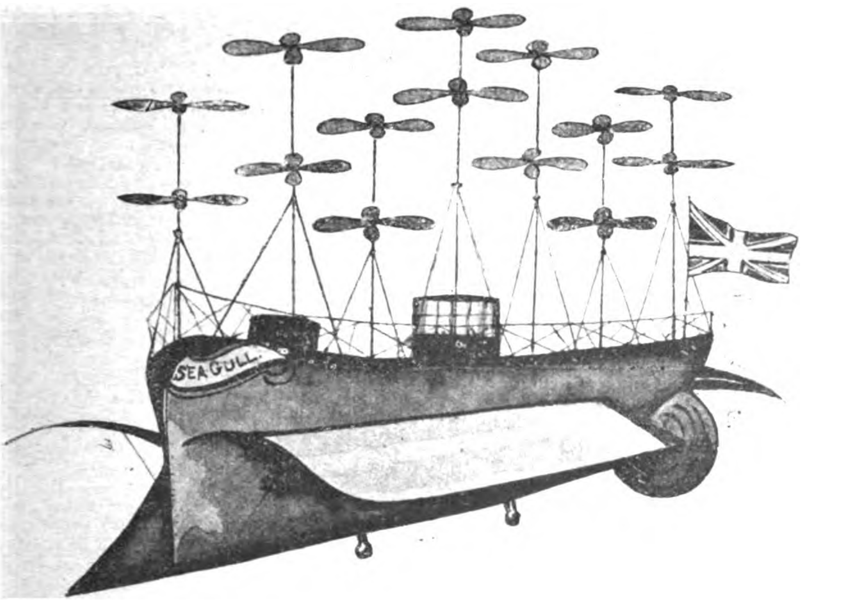

Fig. 2.

may be attained. Of course, man cannot fly by his own unaided efforts; but with suitably constructed wings, and with springs to assist elastic cords to represent the elevator and depressor muscles of the bird and the wing so constructed that it can, when in action, form a true kite, parachute, screw with reversing planes, and a lever to which the air affords a supporting fulcrum (as demonstrated by parachutists, or the bird on extended immovable wings)—flight by man, I repeat, may yet be attained.

I am surprised that such a veteran aëronautical reader as Mr. Wenham should say that a downstroke in still air is almost nil as regards supporting effect. Very evidently he forgot at the moment that the wing, when the bird is once in motion, is entirely indifferent to calm, storm, or oppositionary trend of the current. It creates in calm its own supporting currents, and utilises existing ones. For conclusive proof, who that has seen birds fly in almost absolute calm, or in storm, can doubt for an instant the fallacy of this reasoning? At the same

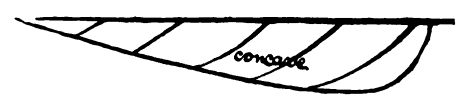

Fig. 1.

time I do not forget that we are indebted to Mr. Wenham for pointing out in this journal as well as at the first meeting of the Aëronautical Society, that an advantage of the long narrow pinions of the albatross lies in the fact that if the current of wind strikes the front margin of an inclined plane, this would be equivalent to the air striking the whole.

J. Sutcliffe (letter 42652) concurs a good deal with my own views. Yet I would point out that not only do "certain small birds" flex their wings, but I have no hesitation in saying, without fear of contradiction, in reality, *every bird does*; those species with short small surface wings flexing the pinions to a far greater extent than the larger and ample-surface winged class, as the eagle, hawk, osprey, albatross, &c. The reason that several attempts at *flying* have failed because the materials of the wings gave way, must undoubtedly have done so; because, in addition to poor construction, they were *rigid*. Had they been plastic and yielding, and conformed to natural types, I sincerely believe they would have been found more practical and efficient. In Fig. 1 is shown an artificial wing, imitating the natural wing in all its natural requirements. To a tapering cane is affixed transverse tapering canes pointing in the direction of the tip, the whole being covered with fine cambric. It is structurally and functionally a reversing screw propeller, reversing its planes as it is alternately raised and depressed. When it is held loosely in the hand and vigorously beaten up and down, it will be found that it darts forward in curves or waves. In the downstroke it darts downward and forward; in the upstroke, upward and forward. In the natural wing as it is impelled upward the body of the bird falls; when it is depressed (and acting as it does against gravity and the air impinging on its concave under surface, to necessitate its beaten with greater force than in the upstroke) the body rises, thus forming the figure of 8 line of progression as stated in my former letter (42625), bearing in mind that the bird is in motion. It should be stated that the wings are elevated and depressed much higher than the body rises and falls; yet, none the less, it really does so. The weight of the bird contributes to flight, and the reason that small birds fold their wings close to their bodies after giving a few swift strokes is because without any supporting surface an increased momentum is given; but when the wings are suddenly expanded, downward motion is transferred into a curved direction. For instance, when an eagle forces the osprey to give up a fish caught, the wings are folded, the eagle falls with ever-increasing momentum, when it suddenly expands its broad wings and vertical tail, and the vertical fall is changed into an oblique and curved movement.

Mr. Challis (in letter 42651) implies that he pins his faith in the vertical beating of artificial wings as the most practical method of obtaining artificial flight, and asserts his opinion that there will be scores of these wings. In my judgment, I sincerely believe that there are two ways of navigating the air—viz., the artificial wing and the screw. He also says that we cannot imitate nature exactly, but in principle only. Precisely. The principle of nature as exemplified in the bird is the screw. We understand that the bird impels itself upward and forward by screw propulsion, resting on concave surfaces at the same time. Screws have also given many encouraging results. Why not, then, employ the principle of nature in our own way, as shown in Fig. 2, which embodies my views, and which I firmly believe is the future of aërial locomotion. The future is to the *air-ship* and not the aëroplane. It is to the screw that the conquest of the air will assuredly fall. E. Wilson.

63, Lower-road, Rotherhithe.

HOW INSECTS FLY—THE MECHANICAL BIRD—AERIAL SCREWS.

[42705.]—Replying to "Desmond" (letter 42673), it may interest him to know that both Prof. Pettigrew and Dr. Marey advance an opinion that insects operate their tiny wings as horizontal screws. My own researches enable me to say that this theory is perfectly correct, and if "Desmond" cares to experiment as follows, providing he has sufficient interest, he will discover the truth of this remark. By holding a common fly by its legs, permitting the wings to move freely, and allowing the rays of the sun to fall on the insect as it is viewed from above, it will be found that although the blur of the swiftly moving wings is difficult to analyse, certain it is that to the expert mind that the wings are in reality screws working horizontally, steering being effected by the aid of the universal joint at the shoulder, which enables the insect to rise, fall, or turn at any degree of obliquity. It is surprising what great weights compared to size of wings some insects have, and which is extremely encouraging when concentrating notes as a basis for designing an artificial flying apparatus on the same principle. For instance, take the stag-beetle, which has a large body with small surface wings, and which, according to the conclusions of M. Lucy, the stag-beetle is 460 times *heavier* than the gnat, yet only has 14 times more surface or wing area. In the case of the bird, compare grouse, with their large heavy bodies and extremely small wings. Yet the "secret of flight" is all on the same principle in aërial locomotion (as in aquatic), and that is the screw. The bird flies in a vertical heliocopheral flight, the insect in a horizontal. Now, can "Desmond" contradict and demonstrate the fallacy of this reasoning? If he thinks he can, I can give a practical demonstration as a conclusive proof. Without desiring to wound his susceptibilities, allow me to point out to him that we are not all theorists, similar to him, judging from his remarks, but base our designs on experiment.

In reply to letter 42675, I wish I had known Mr. T. May was also noting the perfect flying of the seagulls at Blackfriars Bridge as well as myself. With regard to his suggestion to imitate flight by a mechanical bird with artificial wings, the following paper, read before the Aëronautical Society by a Mr. J. Marshall on similar views, may prove instructive. Briefly, he proposed and constructed a system of two pairs of artificial wings—*à la* Dr. Pettigrew—the top pair to act as elevators and propellers, the lower pair as sustainers, operated by steam power. His conclusions are that it is well known that action and reaction are equal and opposite, and that force expends itself in the plane of least resistance; consequently, whatever power is employed to raise the wings reached in a downward direction, and, finding a ground support, was thus enabled to elevate the weight, the wings being an ordinary lever; but when the power necessary to operate the wings was contained in the vessel, quite another action was set up, the force escaping in the path of least resistance, and is non-effective, simply because a counteracting influence is established by reason that the support from the ground is withdrawn. However, discarding the lower wings and utilising an aëroplane, better results were obtained.

"Young Learner" (letter 42674) very evidently labours under a misapprehension in asserting that screws are not effective. Mr. George Davidson, in his lecture to the Aëronatical Society, showed a practical demonstration of aërial screws only 4ft. diam., which lifted a weight of 48lb. per H.P., machinery weighing only 10lb. per H.P. Is this non-effective? I, myself, have made plastic screws of artificial wings which flew splendidly with only indiarubber. Why should not, then, light machinery elevate far greater weights on a proportionately increased scale? If the bird flies on an oblique plane, screws can operate a machine to do likewise. They contain this advantage over other systems in that they desire no preliminary run to create impetus, the revolving screws containing a certain amount of inherent motion. In my first conception, as shown in another column, I have improved on the original in many ways, as, for instance, the screws are so constructed as not to break the column of air, twin screws for propulsion, &c. It has been found that the faster the speed the greater the elevating power, and it is to the foregoing superior advantages the screw possesses over other systems that I so strenuously advocate their adoption. It is obvious that the artificial-bird system is really the same principle in another form; but, as I have frequently pointed out, the screw is the best understood and most practical, the ultimate and successful evolution of which will greatly change the social and political conditions of the world.

It would be unfair to suppose the Editor can lengthen this discussion indefinitely, so this must close it so far as I am concerned.

Edgar Wilson.

BALLOONS IN SECTIONS.

[42706.]—During rather a long life I have heard and read of several accidents to balloons, either bursting, or their being ripped open by contact with houses, trees, &c., some of the accidents being accompanied with loss of life, or severe injuries, to the occupants.

A young married sister was very much impressed on reading an account in the papers of the accident to Mr. Spencer's balloon near West Norwood. During the night it occupied much of her thoughts, it ultimately suggesting to her mind whether such accidents could be prevented, or, at least, reduced to a minimum. Several things suggested themselves, among them, that if the balloon was made in two, three, or more independent sections, each being filled and controlled separately, but still inclosed in the one network, would do this. The idea is so simple I am surprised it has not occurred to me. It certainly is one that would greatly lessen the possibility of a total collapse of the balloon, for it is scarcely possible the whole of the sections could be rent at same time. I cannot say the idea is original. If it is (I certainly have not heard of it before) it may perhaps call the attention of practical men to the possibility of constructing balloons in sections.

Pepys-road. Geo. E. Parker.

THE DANGERS OF CONTACT WITH LIVE ELECTRIC CONDUCTORS.

[42707.]—Dr. Hubert Kath, at the instance of Messrs. Siemens and Halske, of Berlin, has lately inquired into these dangers, and reported the results of his inquiries to the Society of German *Electrotechnikers* at their annual meeting. According to the experiences hitherto made and recorded, the effects of accidental or purposely provoked contacts are of two kinds: fatal contacts and contacts from which recovery is generally possible. The former kill by destroying the nerve centres essential to life. They generally result from large currents of, say, 1,000 and more volts and 2 to 7 ampères, equal to

about 14H.P. *Accidental* contacts with currents of such intensity are happily not frequent. They are mostly used for electrocutions, as at New York.

The second kind of effects are produced by currents of 10 to 100 times less power. Though they prostrate the victims and produce *apparent death*, recoveries are very frequent, if proper means are applied. These sort of currents seem to paralyse the lungs of the unfortunates. The shock experienced produces the sensation of being drowned, and the kind of restoratives are recommended as those used in cases of drowning: artificial breathing and rubbing especially. That the same currents produce often very different effects must be attributed to the condition in which the body who experiences the shock happens to be in at the time. The skin may be moist or dry. The workman's hands may have touched salt, solutions, or have been soiled with filings or other metal dust. He may have weak lungs or be charged more or less with liquor, &c. These facts cannot be too well known, I think. **A. Caplatzi.**

TURN OUT THE TOES.

[42708.]—The following extraordinary statement appears in the *Globe*, which, however, does not supply any names:—"A doctor has announced his belief that in diagnosing a patient's case it is as essential to observe his walk as to feel his pulse. From recent investigations in this branch of what we may venture to call pedestrial therapeutics, it appears that a person in vigorous and robust health walks with his toes pointed to the front, and that as health begins to go the toes turn gradually out and a perceptible bend appears in the knees. It will certainly come as a surprise to a good many people, drill instructors especially, to learn that it is correct, in the best sense of that loosely-used word, to walk with the toes pointed straight to the front. At the same time there seems to be something in the idea. There is a suggestion of force and directness in toes kept rigidly to the front which is not conveyed by the present orthodox fashion of toes turned slightly outwards."

Now a "person of vigorous and robust health" walks just as he was trained to walk when young; but I think it will be found that the majority of people of the educated classes, or those who have been drilled, invariably walk with the toes pointing outwards, which seems the natural way for the foot to tread. I can well remember, when a youngster, having a daily drill of the kind, which consisted simply of putting the heel of one foot against the big toe of the other, and then trying to touch the heel of the other with the toe of the front foot. That is impossible, I believe; but the drill is in use at all dancing academies, and especially at those establishments where they train acrobats and ballet-dancers. I have some recollection of seeing a paper read before one of the scientific societies, in which it was pointed out that those races which habitually walked with the toes pointing outwards were the conquering races of the world. I should like to hear what some of your readers have to say about the matter. **S. R.**

POISONED AIR AND CANDLES.

[42709.]—Candles will burn in air that would instantly kill any man. This was notably shown in a case of suffocation about two years ago at the East-end of London—Blackwall or Poplar. Nobody should descend into a well till a caged bird has been lowered, especially if "foul air is to be found in almost every well," as "M. E. W." says "everyone who knows anything about the subject is aware," p. 580. Caged birds should be kept specially for this purpose wherever wells have to be examined. **E. L. Garbett.**

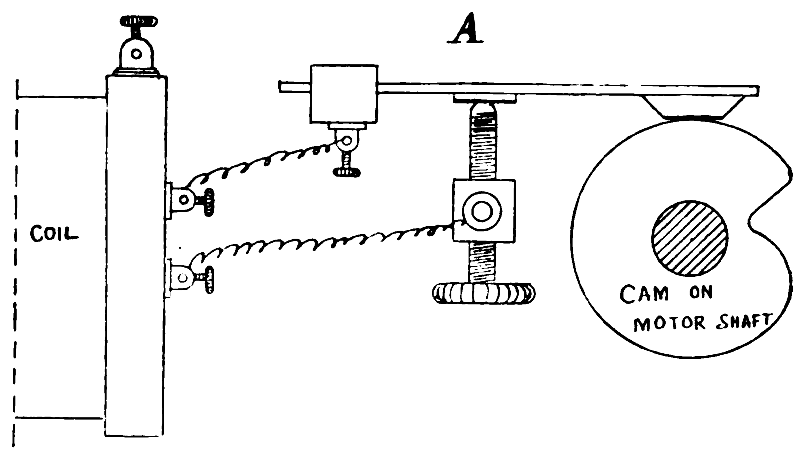
MOTOR CYCLES.

[42710.]—It might be of interest to some of those readers following the very able articles now appearing in the English Mechanic on the making of motor cycles, and especially those who are thinking of making them in accordance with the design set forth, to draw attention to two details which are the subjects of letters patent in this country, and which have been referred to by one or two correspondents.

First, with respect to mechanically-released contact maker, I have the specification before me, it is numbered 19734, A.D. 1895, and the claims are—First: "In an explosion engine a make and brake contact device, acting in conjunction with an induction coil, and having a flexible blade, which is caused to vibrate mechanically by moving some part of the engine substantially as described, and for the purpose specified." Second: "An apparatus or device for controlling the electric ignition of the working charges of an explosion engine, and for regulating the speed thereof, substantially as described with reference to the accompanying drawing." The drawing marked "A" is a facsimile of that in the above-named specification.

Those who would like to use a mechanically-released contact-maker might be glad to know that

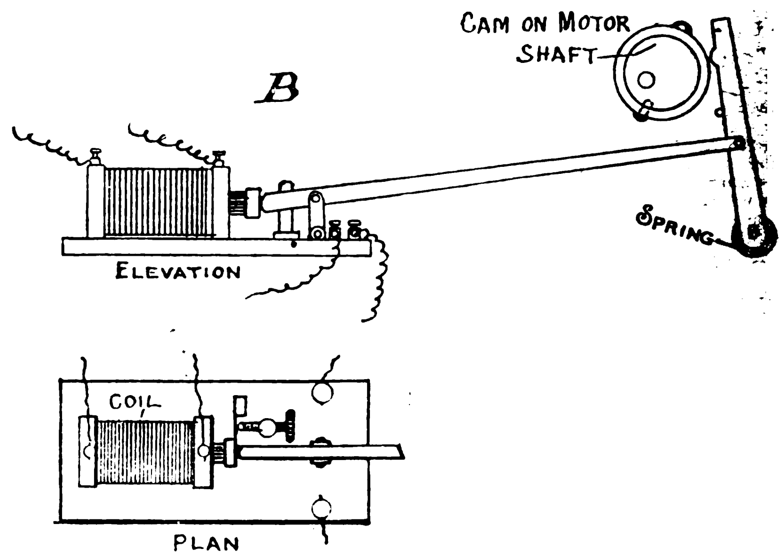
A



the one referred to is not the first arrangement of mechanically-released contact-maker which has been suggested, and, I believe, used. I attach a drawing marked "B" of this device. It will be seen by comparison of the two devices that in the first named the cam directly releases the spring contact-maker, and enables it to come in contact with the screw point, and in the second through a lever and strut pressing against the spring blade by means of a more powerful spring, and releasing it by the cam on the motor-shaft.

Second, with regard to the securing of the cylinder to the crank-casing by long bolts lying

B



parallel with, and close to, the cylinder walls, this is claimed only in respect of explosion engines, and the "invention" appears to be merely the application. It is an old and obvious arrangement even in the case of cylinders and cylinder cover; but I believe it is one of the "master patents" of a well-advertised concern, and unless a user intends to stick to it through thick and thin, for the present it would be better not to bother with it. It appears to me to have no special merit where castings are employed for the cylinders.

I have been looking for a clear and direct anticipation of this arrangement, having seen it, I believe, in some old gas-engines, in order to settle the matter in the interest of readers of the article on motor bicycles; but up to the present I have been unable to obtain what I want.

Referring to remarks made by several writers recently in your columns respecting motor cycles, it has been said that a high speed cannot be got out of a long-stroke engine. If 1,500 revolutions per minute is a high speed, that can easily be got with a stroke equal to two diameters, and even two-and-a-half diameters. I have used both proportions. The chief objection to long strokes is, they necessitate a larger flywheel, and for motor cycles this is objectionable, as room is scarce. As regards the use of gun-metal and phosphor bronze for cylinders, I believe one or the other is successfully used on some of the Bentz cars. If the metal is hard and the piston and cylinder end are both made of it, I do not see why it would not do better than soft cast iron.

Regarding motor bicycles, it is difficult to arrange a motor upon the ordinary safety, taking everything into consideration. I would suggest using a front driver with 30in. and 24in. wheels, and applying the motor to the smaller back wheel. I am making one for myself on these lines, and when finished I shall be glad to give my experience of its running and the main particulars of its construction.

Liverpool, Aug. 8. **R. J. U.**

REDUCING INTENSITY OF LIGHT.

[42711.]—In reference to Mr. W. F. A. Ellison's remark (letter 42662, p. 576) about a perforated stop, I think the work in which he has read of its being used must be Chambers' "Handbook of Astronomy," where, on p. 285 of Vol. II. 4th edition, is the following:—"Dawes adopted and recommended the practice of covering the entire object-glass with perforated cardboard, such as that employed in Berlin wool-work. The effect of this expedient in producing sharpness of definition he considered to be very marked. When the object to be viewed was not bright enough to bear the loss of light arising, he found that something like the same good results might be obtained with a piece of cardboard of the size of the object-glass pierced with holes of equal size (about ½in. in diameter), arranged in concentric circles."

About a year ago, I tried the effect of placing a piece of perforated cardboard, blackened dead-black, immediately in front of, and resting against, the o.g. of my 3in. achro., and found, like Mr. Ellison, that, although it served the purpose of reducing the light admirably, it was impossible to get any definition at all. It made the sun appear to have 3 or 4 concentric limbs, as Mr. Ellison says, and I also noted they were alternately coloured purple and green, the colours being exactly like those of the secondary spectrum, but not so bright. I should be glad if any of the contributors to the English Mechanic on optical matters could explain the discrepancy between Dawes's statement and the result of Mr. Ellison and myself.

Aug. 14. **S. B. Gaythorpe.**

In connection with the visit of the Société Belge de Geologie, an excursion to Charlton, Erith, and Crayford has been arranged by the Geologists' Association for September 9. Members who can speak French are specially requested to attend. Mr. A. E. Salter, 14, Amersham-road, New Cross, S.E., is the excursion secretary.

REPLIES TO QUERIES.

*** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96178.]—**Small Telescope.**—If Frank Schlaudeman will get a dark glass head, he can limit the intensity of the light. The better plan, though, would be to get a strip of neutral tint in the form of a wedge, with a plain glass of the same form, and place the thin end of one to thick end of the other; he would get a great range by viewing the image through it. THEODOLITE.

[96183.]—**Fitting Conical Axis.**—To fit a theodolite centre on axis, the hole in the hollow or middle centre must be broached out with a good broach, and then ground out upon a brass plug, turned to fit the whole length of the hole, using pumice-stone crushed on a metal (brass for preference) plate with oil. This grinding requires to be carefully done. After a little grinding, the hole must be cleaned out by twisting a piece of rag and pulling it through, and the plug wiped clean must be twisted round in both directions will show where it bears. It must then be made to fit all along as before, a very old smooth file being used for this purpose. When the plug or grinder fills the hole all over and the hole appears polished, a mandrel must be fitted with which to turn the outside. This should be of steel with brass collars soldered on it, so that these collars will fit the ends of the hole about ½ or ¾in. The mandrel should have sharp centres running in brass holes, and be coned to 60°. When roughed out, the male centre, which is best made of bell metal, should be fitted and ground in similar to the grinder, and, when nearly let down to its shoulder, be finished by grinding with scraped blue-stone and oil. The mandrel must now be fitted again, and should have about the same length of bearing at each end and also fit with equal force. The outer surface can now be fitted into its socket in the same manner. To get a good result it is necessary to do it all between dead centres. In grinding the centres in, care must be taken to ease the parts that rub hard with a graver. THEODOLITE.

[96184.]—**Graduating Centres.**—There is no occasion to put lines; the directer will centre the limbs by the central hole. THEODOLITE.

[96185.]—**Tribach Stage.**—This is better than the usual four screws if well made and designed. The screw fittings should be of good length and fit, and the screw-holes cut, and a clamp-screw fitted, to make up for wear. THEODOLITE.

[96256.]—**Electros.**—The copper shells must be put on a hot plate, the temperature of which is gradually raised. One method is to place them on an iron plate floating in a bath of molten stereotype metal. The back of the shell is coated with chloride of zinc as the flux and stereo. metal is filled in to "back up" the shell. The solder may be ordinary tinman's solder or alloyed tinfoil, which is to be melted, and brushed over the back of the shell before pouring in the metal. If the shells twist, they must be kept flat by weighting down until cool. Properly speaking, there is no such thing or process as cold soldering; but an amalgam can be made which acts as a sort of solder without the application of external heat. S. R.

[96260.]—**Northern Heights.**—If by this phrase the parts known as Highgate, Hampstead, Mountview-road, Priory-road, and Muswell Hill are meant, I would suggest that the words "even after traffic and railway work ceases" require some explanation. I know the district well, and I should like to know when railway work "ceases." As soon as the crush of the passenger traffic is over, the goods' trains come on the scene, and run all through the night. I have no knowledge of the special reference to increasing vibration of the ground; but it is quite a mistake to suppose that the railway traffic ceases. It does not; a microphone would detect it all night long. ESPAR.

[96333.]—**A Monkey Puzzle.**—If each of your correspondents taking part in this discussion gave a strict mathematical definition of the meaning he attaches to the statement "the man has gone round the monkey," it is probable that no two of them would agree. Further, it is quite likely that the majority of such definitions would be ambiguous from a strictly scientific standpoint, and therefore useless. In almost every reply so far published the writers have got fogged over one or other of the following points:—1. The distinction between relative and absolute motion. 2. The consideration of orbits which are not plane figures. 3. The probability that the transitive verb *to move round* is invariably used with reference to some plane, though not necessarily to movement in that plane. 4. The old difficulty of the "non-lunar-rotation men," who confound the movements of the several particles of a body with regard to each other, and the movement of the body as a whole with regard to another body. The whole question hinges on the meaning we give to the transitive verb "to go round." Your correspondents have so far confined themselves to examples of the use of the word colloquially in various ways. The method by which restricted meanings have been arrived at is obvious. Thus, when we go round anything we usually "get to the other side of it," therefore to go round anything means to get to the other side of it; but this is not logic. When "Lyttle Booke's" friend went half-round the house on the turntable he did not get to the other side, and why? Because the house "went round." (To go round, verb intransitive, with a totally different meaning—i.e., to revolve on an axis either within or without the body.) "Little Booke" argues that his friend did not go half-round the house, and, no doubt, it would have been wiser to remain stationary, so that by not going round he would have got round! But a truce to this nonsense. The expression has long been used in a strictly scientific sense, which I would attempt to define thus:—(1) Suppose the path of a point P relative to a point O lie in a plane, and O lie in the same plane, and θ be the angle that O P makes with a given straight line O X in the said plane and fixed relative to O. Then if, during a given time, θ has every value from O to 2π at least once, then P will have revolved round O at least once. (2) Suppose O lie not in the same plane as the path of P, or suppose the path of P be not a plane figure (in practice it never is); then P will have revolved round O referred to any plane, if the projection of P on the given plane have revolved round the projection of O on the same plane. (3) A body A will have revolved round another body B referred to any plane if every particle in A have revolved round each and every particle in B referred to that plane. According to these definitions, your correspondent does go round every object in Grosvenor-square. The man who walks round St. Paul's has been round the cross. The rim of the wheel does revolve round the hub, and the spokes do not suffer in the least, for they also revolve round the hub at the same angular velocity. With strict scientific accuracy we all go round the earth every 24 hours (here note the confusion between motions referred to different points, or relative and absolute motion). The two boxers continually "circulate" round one another, though they face all the time; and lastly, "J. H. R." certainly goes round his ring, though why this should "settle the matter" I do not quite understand. Of course, Mr. Bottone and others are at liberty to give any meaning they like to the words "go round"; but, at least, we should have "definitiveness," as "Lyttle Booke" puts it, which could only be secured by an accurate scientific definition of the meaning they adopt, and this we have not yet seen. C. P.

[96333.]—**A Monkey Puzzle.**—I do not think I assert that a state of things exists at 2ft. which does not exist at 18in. or 12in.; 2ft. was simply taken as an example. Suppose the monkey to be a geometrical point in the centre of pole; when the man has walked round the pole, has he not also been round the point? Now remove the point any distance, and let both go round centre of pole keeping in unison, is not this result different? I agree with "Scorpio" that the difficulty lies in the word "round." It would be interesting to know "J. R. J.'s" views on this puzzle. F. C. S.

[96333.]—**A Monkey Puzzle.**—Might I suggest the following supposition to the correspondents who have written on this subject? Suppose the man who walked round the pole had a ball of some 26 yards of string, and that on commencing his circular tour he tied one end of the string to a peg fixed in the ground, and that as he walked he kept unwinding the string and letting it lie loosely in his track, and on arriving at the peg whence he started, he tied the two ends of the string together. The following questions now naturally suggest themselves:—1. Does the string encircle the pole on which the monkey is perched? 2. Does the string also encircle the monkey which is perched on the pole which is encircled by the string? If not, how has the string got between the monkey and the pole? 3. Does not the string mark the path of the man round the pole? 4. If so, does it not follow that the man went where the string lies—i.e., round the pole. Conclusion: If the string encircles the pole and monkey, the man went round the pole and monkey. If the man did not go round the pole and monkey, then the string does not encircle the pole and monkey. Each reader is at liberty to pay his money and take his choice. LOW FELL.

[96333.]—**A Monkey Puzzle.**—"Lyttle Booke" seems to have overlooked the first part of my reply, where I took the moon's motion as an illustration. It seems to be the opinion of many correspondents that if you see every part of the monkey in succession, you must have been "round" it; but not otherwise. This will happen, however, if the man stops, and the monkey goes on rotating. Has he been "round" it then? It is a question of verbal definition entirely.

Oystermouth. SCORPIO.

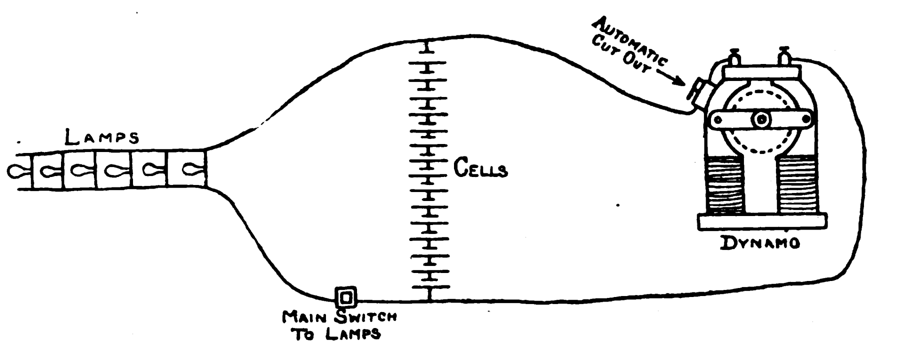
[96347.]—**Hydraulic Press.**—The compressing force or power is found from the ratio of the plunger and ram to each other, and from the ratio of the leverage of the pump handle. Thus if the plunger be $\frac{1}{2}$in. or $\frac{4}{8}$in. and the ram 6in. or $\frac{48}{8}$in. in diameter, and the arms of the pump handle as 1 to 4, then—

4 squared =	16,	and 48 squared =	2,304
Multiplied by	1	and	4
Equals—	16		9,216

—i.e., as 16 to 9,216, or as 1 to 576, so that a force of 1lb. applied at the long end of the pump-handle would produce a pressure of 576lb. on the ram. N.

[96372.]—**String and Key Experiment.**—In reply to "F.R.A.S.," p. 575, I might say that, as far as I am concerned, imagination never entered into the experiment at all. I read of the experiment (where, I cannot recall), and tried it with various persons of both sexes, and at different times. The result was always the same. I submitted it to a scientific friend, and he, in my absence, obtained the same result, but could offer no explanation. I admit I was somewhat sceptical when I first tried it; but had I not been convinced that it gave the results stated, I should not have sent it to the "E. M." It would be interesting to hear of other readers' successes with this. F. C. S.

[96389.]—**Electric Lighting.**—To MR. BOTTONE.—Procure a good automatic cut-in and cut-out. Arrange this on the dynamo. You will need 25 cells to keep up a voltage of 50v., and the dynamo must give 65v. for charging. The cells need not be large for your purpose. Then arrange the cells in series with one another, but in parallel with lamps, as shown in annexed sketch.



S. BOTTONE.

[96402.] — **Grammaphone.** — "W. E. P.," Limerick, has asked for advice respecting discs which have become impaired by use, I take it, and not faulty at the time of purchase. It is, in my experience, not an uncommon defect, and although, as Mr. Bennett says, it cannot be remedied without running the risk of damaging the next line, I have found the best way to get over the difficulty is to use a sharp penknife, and with the point make a small shunting groove from the fault to the next good line, keeping the angle very acute, as in a railway shunting. By these means I have found that the needle is helped along, and the record very slightly the worse, if any. Certainly it is better than lifting the arm by hand, and better than throwing away a record which may have nothing else the matter with it. I have found it good to make several shunting grooves to insure the needles catching in one. The needles which I use for my machine are ⅝in. at the time of purchasing, and I should feel obliged to Mr. Bennett for his opinion as to the advantage of shortening after he has given the matter a trial. J. R. J.

[96403.]—**Burnt Steel.**—It is doubtful whether any remedy will be found. Burnt steel is steel that

has had the carbon burnt out of it, and if it were possible to put carbon into iron by simply dipping it into some magic solution steel manufacturers would soon do so instead of employing the present costly and tedious process of converting iron into tool steel. Years ago, when I worked in a smith's shop in Shere, Surrey, a man came along the road and asked for work. There was none to give him. He then offered for sixpence and a drink of beer to let us into a great secret for restoring burnt steel. We agreed. He took an old flat file, made it white hot in fire, quenched it, and broke the end off to show it was burnt. He then produced some white powder, which he said was equal parts of salt, saltpetre, and salammoniac. While these were being dissolved in water, he accepted part payment for the job in beer. The file was again heated to red, and thoroughly well hammered into a cold chisel; heated again to red, quenched in the magic solution, the temper drawn, and a very good chisel it was. The man took his sixpence, with some more beer, and departed, all parties being satisfied. Some time after, another hand was engaged, a Sheffield man, used to making vices. He scoffed at the idea of the magic solution, and undertook to produce the same result, using only cold water, and his chisel was as good or better than the other. He then explained to us, who seldom worked steel, that it was the hammering that had done the trick, and that the files had too much carbon in them for ordinary tools. Some of it had been burnt out, and the particles driven up close together again by the hammer. It is only by gross carelessness that steel is burnt, and new steel is now so cheap that in most cases it must be safer to get a new piece than to go on working it.
C. G. NORTON.

[96403.]—**Burnt Steel.**—Burnt steel may be restored to its normal state by slowly reheating and annealing. It would be interesting to know if "Regent's Park" has ever tried any of his wonderful prescriptions; also the reaction that takes place when, after the burnt sample is heated to cherry red, it is plunged "in mixture when steel is cold"!
BAZIN.

[96405.]—**Crystoleum Painting.**—"Amicus" might try the following. I have not tried it myself; but, with the intention of making a crystoleum, I thought out what would certainly prove a much simpler process. Get a good negative, and take a positive from it on a process plate by contact printing, as with lantern-slides. Select the smoothest of the plates. In developing, take care not to lose the high lights—let the shadows take care of themselves. Don't miss out the alum bath. After that, and when the positive is thoroughly dry, "Amicus" will have to satisfy his own taste. He may paint with oils direct on to the film, or first give it two coats of amber or other transparent varnish; then sandblast it when hard, so as to soften the colours, which he would then paint on. At any rate, whether sandblasted or not, some good negative varnish would do no harm, but would act as a medium.
LYTTLE BOOKE.

[96407.]—**Cancer.**—The English name of the Chelidonium majus is celandine. "It is found in waste places, and in old walls in this country, and may be recognised by its small yellow flowers, and the orange-coloured juice which exudes from its stem when plucked. This juice is poisonous, and is a popular application for the cure of warts. It has been used with success in the treatment of opacities of the cornea, and been administered internally as a stimulant." A full description of its virtues will be found in old Culpeper, in which he recommends it as "good in old, filthy, corroding, creeping ulcers (answering to our present cancer), wheresoever to stay their malignity of fretting and running, and to cause them to heal more speedily. The juice rubbed often upon warts, will take them away, and applied to other such like spreading cankers, will quickly heal them." From this description the action of the remedy appears rather that of a natural solvent than a stimulant, which would be the right property, and the course I have always pursued in the cancer cases I have had to treat. I have never used the celandine, so I cannot say whether it would have that particular effect; but should I meet with another cancer case, I will give it a trial; but in a preparation of the simple herb rather than the juice, with its imputed poison.
INCOG.

[96409.]—**Trees Overhanging Garden.**—The right to lop off protruding boughs is as has been told, but not until the winter months, when the sap goes down. As to the offending boughs being the property of the tree-owner, let him cut them off and remove them at his own expense; but no law requires the injured party to send every bough, twig, and leaf, say, 100 miles off, to suit the late owner's convenience. If possible, let them be neighbourly, and settle it.
J. B.

[96411.]—**Wimshurst Machine.**—"Somerset Lad" will find that most of the coloured glass is not suited for influence machines. Before selecting any glass he should test its quality as an insulator. He may do this by warming a strip, then rubbing it with a silk handkerchief, when, if of good quality, it will attract small scraps of paper. The cracking of the plates from centre probably is due to an imperfect cutting of the hole, and the commencement of fracture existing at time of purchase. These imperfections grow day by day, owing to the unequal expansion of the glass.
J. W.

[96423.]—**Filtering Water.**—By having a rain-water separator of C. G. Roberts, Haslemere, Surrey, you can get fairly clean rain-water. In the way you speak of, you cannot.
REGENT'S PARK.

[96425.]—**Wimshurst Machine.**—The defect may be threefold. (1) The jars may not insulate well. Varnish these carefully, from tinfoil upwards. (2) The plates may have been "fingered" a good deal in cutting, and, being fitted with sectors, hence greased and oxidised on the surface. Make up a thick cream of magnesia carbonate and water; paint over the plates with this cream. Allow to dry thoroughly, then wipe off with a dry flannel. (3) The brushes do not touch the plates equally at all periods during rotation. See to this, and get the touch of the brushes as equal as possible.
S. BOTTONE.

[96425.]—**Wimshurst Machine.**—The obstinacy in starting is unquestionably due to the brushes or the sectors being either dirty or lacquered. The essential feature to produce freedom in the excitation is an absolutely metal connection between brush and brush, and also between each brush and its sector. Dealing with any one of the plates, the two sectors which are in the same line of diameter should be touched by the two brushes at the same moment.
J. W.

[96426.]—**Magnetism.**—Vitreous: Glass and slag. Stony: Slate, marble, stoneware, steatite, porcelain, mica, asbestos. Resinous: Shellac, resin, beeswax, various gums, bitumen, ozokerit. Elastic: Indiarubber, guttapercha, ebonite. Oily: Various oils, fats of animal and vegetable, solid paraffin, petroleum oil. Cellulose: Dry wood, paper, fibro-celluloid.
REGENT'S PARK.

[96426.]—**Magnetism.**—The best, and in fact the only, thing that will intercept the lines of magnetic force is a sheet of soft iron.
S. BOTTONE.

[96427.]—**Boot Polish.**—Try this stain: Oxalic acid 1oz., alum 1oz., annatto 1oz., isinglass ½oz., sugar of lead ½oz., dissolve in water (1 quart) for ten minutes. Apply with sponge. To keep leather supple, a few drops of cod-liver, castor-oil, or vaseline sponged or brushed over.
REGENT'S PARK.

[96429.]—**Steam Pump.**—The cause of the noise in your steam pump is that where it runs fast the water cannot follow it; a vacuum is formed, and when it meets the water the shock is heard.
WM. GRIMSHAW.

[96433.]—**Locks on the Trent.**—The Trent Navigation now begins at Sawley, about 100 miles above the Humber; the locks between that place and Burton-on-Trent having been long abandoned. The river is joined by the Derwent, and by the Trent and Mersey Canal at Sawley. Thence the locks are three miles, Cranfleet dock, where the Soar runs in from Leicester, &c. Seven miles, Beeston, two locks; 13 miles, Holm Lock; 34 miles, Newark Lock; 35 miles, Nether Lock, where one gets on to the tidal water. Beware of the "æger." Loughborough is not on the Trent, but on the canalised part of the Soar, about 9½ miles above its junction with the main stream at Sawley. There are seven locks between Loughborough and Sawley. Between Loughborough and Leicester there are some eleven locks in 15 miles. There is a book, "A New Oarsman's Guide," published by G. Philip and Son, 32, Fleet-street, E.C., which gives full information respecting all the navigable waters in Great Britain and Ireland.
COXPLANKET.

[96438.]—**Glass for Wimshurst Machines.**—About $\frac{3}{32}$in. thick for machines from 12in. to 18in. diameter, and ⅛in. for machines from 18in. up to 24in. diameter. Beyond this allow $\frac{1}{16}$in. increase for every extra foot in diameter. The best way to test the glass is to wipe it with a dry, hot diaper, lay a sheet of tinfoil under it and another over it, and see whether it will retain a charge given to it by any electrical machine. The tinfoils should be smaller by 1in. all round than the glass plate to be tested.
S. BOTTONE.

[96438.]—**Glass for Wimshurst Machine.**—The common, but flat, window glass is the best quality for these machines, and may be used up to, say, 2ft. 6in. diameter. To test it, you should get a strip, then warm it, and then rub it with a silk rag. If the quality is good, it will attract fragments of paper.
J. W.

[96441.]—**Wimshurst Plates.**—To MR. BOTTONE.—Coloured glass is generally not so good as ordinary window-glass. See also reply 96426, then test your glass as therein advised. Plates generally crack from centre, because the boss fits too tightly, and the glass is not mounted elastically. See reply 96391, p. 582.
S. BOTTONE.

[96442.]—**Waste Rubber.**—I suppose the querist does not know what he is asking for, or, rather, does not apprehend the meaning of his question. There are some patented methods of desulphurising indiarubber, and some have been described in back numbers; but it is quite certain that any really successful method of restoring vulcanised rubber to the state of pure rubber would form the subject of a patent, and it would be a very valuable patent too. The process of "curing" seems to permanently change the nature of caoutchouc. See p. 316, last volume.
S. R.

[96439.]—**Quadratic.**—

$$\sqrt{x+3} + \frac{\sqrt{x-2}}{\sqrt{x+3}} = \frac{11}{3} = 3 + \frac{2}{3}.$$

Now it is pretty obvious, from the symmetrical nature of the equation, that $\sqrt{x+3}$ is integral, and equals the integral part on the right-hand side —i.e.,

$$\sqrt{x+3} = 3.$$

$$\therefore\ x + 3 = 9. \quad \therefore\ x = 6.$$

The same result is obtained by equating the fractional parts on each side. We might have proceeded as follows:—Let $\sqrt{x+3} = p$ and $\sqrt{x-2} = q$.

Then— $p + \frac{q}{p} = \frac{11}{3}$

or— $p^2 + q = \frac{11p}{3}$

or— $3p^2 + 3q = 11p$

or— $3p^2 - 11p = -3q.$

Here we have an indeterminate of the 2nd degree, and by giving to q the values 1 . 2 . 3...., we find p, the only value that satisfies, is got by making $q = 2$, thus:—

$$p^2 - \frac{11p}{3} = -2.$$

$$\therefore\ p^2 - \frac{11p}{3} + \frac{121}{36} = \frac{121}{36} - 2 = \frac{49}{36}.$$

$$\therefore\ p - \frac{11}{6} = \pm\frac{7}{6}.$$

$$\therefore\ p = \frac{18}{6} \text{ or } 3, \text{ or } \frac{4}{6} = \frac{2}{3}.$$

Therefore, as before, $x = 6$ — the second value not available. Neither of these methods is entirely satisfactory, as they are not strictly rigid. But there are many equations which cannot be solved in any of the ordinary direct methods, of which this is one.
INDUCTORIUM.

[96439.]—**Quadratic.**—The "quadratic" to which "Ontario" refers—viz.:—

$$\sqrt{(x+3)} + \sqrt{\left(\frac{x-2}{x+3}\right)} = \frac{11}{3} \text{ or } 3\tfrac{2}{3},$$

is a doubtful species of that genus, for when reduced it takes the form (putting $y = x - 2$)—

$$81y^4 - 720y^3 - 9{,}596y^2 + 8{,}620y + 380^2 = 0,$$

for which modern theory requires four solutions. This probably resolves into two quadratic factors, which are not immediately obvious. Intrinsically, the original equation is of "one" dimension, being of the form—

$$\sqrt{(x+a)} + \sqrt{b} = c, \text{ and } x = c^2 + b - a - 2c\sqrt{b}.$$

We may solve it as a simultaneous equation by putting—

(i.) $x + 3 = a^2$

(ii.) $x - 2 = b^2$

Whence— $a + \frac{b}{a} = 3 + \frac{2}{3},$

Where by inspection we see $a = 3$, $b = 2$, $x = 6$.

Or, subtracting (ii) from (i), we have—

(iii.) $5 = a^2 - b^2$

the difference of two square integers, and since—

$2^2 - 1^2 = 3$ which is too small; the next trial gives $3^2 - 1^2 = 8$ which is too large, and, therefore, we get $3^2 - 2^2 = 5$ which satisfies the condition.
HENRY T. BURGESS.

West Norwood, Aug. 12.

[96443.]—**Platinum.**—To MR. BOTTONE.—You can distinguish between platinum foil and tinfoil by holding the foil in the flame of a spirit-lamp. Platinum will stand a white heat and will come out of the ordeal as bright and as clean as when first put in the flame, while tinfoil, on the contrary, will melt almost immediately it touches the flame.
S. BOTTONE.

[96444.]—**Porcelain Enamel for Glass.**—I think you will have difficulties in getting any enamel that does not require firing. They are mostly sold by English colour-makers. Samples perhaps from Hancock, Worcester; Emery, Cowbridge, Stafford; Wenger, Hanley. Lacroix, of Paris, is said to be a first-class maker. If you can make one out of water-glass and zinc-white, it may perhaps suit your purpose; but whether it requires heat cannot say.
REGENT'S PARK.

[96446.]—**Saccharine as Food.**—Cane sugar is not susceptible of the alcoholic fermentation. It

must be first of all converted into glucose (i.e., grape sugar), which can occur through the action of diastase if the action of cane sugar be added, as is seldom done, in the mash-tun; but is more usually effected by the action of yeast in the fermenting-tun. Its employment, therefore, has this disadvantage over that of ready-made glucose—viz., that more yeast is required. This increases the possibility of more dead yeast cells being acted upon by the alcohol, with the production of "yeast-bite." Further drawbacks to its use are that the beers brewed with it attenuate excessively, and have a tendency to produce diarrhœa, while the common raw sugar contains a great many nitrogenous impurities, which produce unsound fermentations, and when these are used frequent changes of yeast and quick consumption are necessary, &c. Another kind, which is made for brewer's use, is called invert sugar—known commercially as saccharium. The material is in this instance cane sugar, and the inversion is effected by dilute acid. It is higher in price than the glucose, and has the further disadvantage of being in a semi-moist state. Dr. Burney Yeo does not advise saccharines or sugars for diabetics.

REGENT'S PARK.

[96448.]—**Worm in Desk.**—Procure a pint of good clean benzoline; dissolve in this 1oz. of naphthaline (albo-carbon). Take your dish out of doors, so as to be out of the way of fire or candle, &c. Now paint the desk all over liberally with the benzoline, until you have used it all up. Allow the desk to dry out of doors. You will have killed all insect life by this treatment. S. BOTTONE.

[96448.]—**Worm in Desk.**—For several remedies see pp. 19, 42, 71, and 560 of the last volume. There are several replies about worms in furniture. I generally cure the trouble by rubbing in lard—forcing it, and then melting it; but it may be possible to force oil in. Anything of that kind will kill the insects. M. T.

[96448.] — **Worm in Desk.** — Apply strong corrosive sublimate solution to spots, and if colour is affected expose to the action of ammonia fumes or by brush. REGENT'S PARK.

[96451.]—**Moles.**—Lunar caustic, acetic acid, or Chelidonium majus will remove warts.

W. EWART-GIBSON.

[96451.]—**Moles.**—External use of creosote:—1 drop of tincture, 80 drop of water; apply two or three times daily. Also croton oil, or seton threads.

REGENT'S PARK.

[96452.]—**Meal Powder.**—This is "mell cake" broken down to powder between plain rollers of gunmetal usually; but why not buy of "Pinnel." If any difficulty in getting it, F gunpowder (grain) may be crushed in a leather bag, by laying bag on hard surface, and beating it with a hammer, then sift through fine sieve; leather such as used for shoes. See "Pyrotechnists' Treasury, 1887" (Chatto). REGENT'S PARK.

[96453.] — **Capacity of Accumulators.**—To MR. BOTTONE.—(1) Because, owing to the porosity of the surface of the plates, the actual surface exposed is nearly six times as great as the mere superficial area. The superficial area of each plate, counting both sides, is, 5in. by 4in. by 2in. = 40in., hence the seven plates equal 280sq.in., or nearly 2sq.ft.; but owing to the "pits" the actual surface is much greater. (2) No; better renew the acid, because when the chromic-aid has given up its oxygen, it is of no further use as a depolariser. When the chromic solution turns olive-green it is spent, and is only of use to kill weeds in the garden path. S. BOTTONE.

[96454.]—**Wimshurst.**—To MR. BOTTONE.—Take a piece of twine about ⅛in. thick and 20in. long; pass it between the plates, and tie it by its centre once round the spindle, bringing the ends out at opposite diameters of the plates. Now cut these ends back so that they reach to only ⅛in. of the edges of the plates. S. BOTTONE.

[96454.]—**Wimshurst.**—W. Milnes is wrong in supposing the vulcanite discs were drawn together "all round the periphery." If he again looks he will find them drawn together at the top and the bottom, but that they are thrust asunder at the horizontal line—or, in other words, at the collecting combs. The difficulty may in great part be overcome if he places another washer, or perhaps two more washers, on the axle. The discs are probably rather thin for their diameter, but thicker discs will cost proportionally more. J. W.

[96459.] — **Meteorology.** — I should certainly doubt that the statement of high cirrus clouds travelling at the rate of 144 miles an hour under any circumstances; as weather signs, I have watched them for many years, and have always observed them as having the slowest motion of any form of cloud, as being formed in a region far above the influence of any storm current. As weather signs, I have always looked when there are the indications of the breaking out or existence of more or less violent storms in the remote distance, of which the movements of the barometer may show the possibility of their reaching these shores before being exhausted. The last three days there have been some very fine displays of "cirrus," and especially last evening (August 13). They were very high, and I had the greatest difficulty to discern any motion. They gradually resolved into patches of vapour, which, reflecting the sunset, filled the entire heavens with fire. This morning the sky is almost obscured by heavy clouds, the temperature 1° above yesterday. During the night the barometer has fallen one-tenth, showing our position on the outlier of a remote depression and storm area, the influence of which is shown by the influx of heavy cloud from the S.W., over the long-prevalent and existing E. The change may be only temporary, and the barometer re-ascend to about the 19th, with again much cirrus as the portent of distant outbreaks. Then may come a temporary cooler wave as the result of extreme electric phenomena. TEMPUS.

[96460.]—**Dissolving Amber.**—Amber will dissolve without previous preparation in *chloroform* and *benzole*. If previously roasted and powdered, it will dissolve in turpentine and oil of lavender. I believe it dissolves in amyl acetate, but this I have not tried. S. BOTTONE.

[96461.]—**German Baths.**—Carlsbad, according to E. Lee (1846) on "Mineral Springs of Germany":—One good resolvent analysis in 1822 of the Sprudel by Berzelius in 16oz. of water:—

No mention of Nauheim, but particulars of some 29 other waters are given. You can get bottles of some of them at London agencies, and you could test at home instead of expense, which may run into months abroad. The Carolinen is a chalybeate.

REGENT'S PARK.

AN incident of the present state of the copper market is the receipt at New York of a lot of 9,989 bags—about 250 tons—of copper coins from India. These coins, which are consigned to the Orford Copper Company, are shipped as scrap copper, simply because they are worth more, at the present price of copper, than their face or coin value.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

USEFUL AND SCIENTIFIC NOTES.

THE Knapp roller boat recently set out on a voyage from Toronto. The roller boat would not roll, and, according to the *Canadian Engineer*, became unmanageable even in a moderate wind. Five days after leaving Toronto the roller was reported as being tied to a tree about two miles west of Bowmanville, Ontario, having rolled forty-one miles in five days.

Moulding Glass.—The following method of moulding glass, adapted to the manufacture of articles open at one or both ends, and of any reasonable dimensions, is attributed to M. L. Appert, of Paris. The object is attained by means of a mould open below for admission of a core, which may be in one piece throughout or divided transversely into two portions separable from each other. The core is similar in form and dimensions to the article which it is desired to mould. The mould, which is divided lengthwise into two or more portions, to admit of the finished article being removed, is provided with lateral grooves or depressions, to prevent the fluid glass from being pushed upward by the core instead of being compressed against the wall of the mould. Means are provided for applying heat to the lower portions of the mould. In applying the process, a core with a conical point is used when making articles open at both ends; whilst for articles closed at one end, the end of the core is of the same form as the bottom of the article required; and the mould is provided with a movable cover, arranged to oppose a yielding resistance to the glass, and having vents to allow of the escape of the air and the excess of glass, such vents being, however, regulated, to prevent ejection of more than is desired of the mass of glass. The core is withdrawn to its lowest position in the mould, then the fluid glass poured in, and the core forced upward until it has finished its course, when the excess of glass is cut off.

THE following directions as to taking metal samples for analysis are given by M. Ad. Carnot, Director-General of Mines:—In order that the sample analysed should represent the average composition of the whole mass to be analysed, it must be taken of sufficient thickness, or partly from the surface and partly from the centre, because sometimes there is considerable difference of composition between the two, especially as regards the carbon content, which is higher at the surface than at the centre in grey pig rapidly cooled, and lower at the surface in the case of wrought iron. When a drill is used it should be made to pass completely through the metal while forming fine and equal borings, so that their mixture shall represent as faithfully as possible the general composition of the whole. Hard and brittle pig-irons, such as white forged pig and spiegeleisen, may be reduced to pieces by hammer on an anvil, and then pulverised in a steel mortar, the inside surface of which has been hardened. Grey pig cannot be pulverised by impact; but a fine powder may be made by a hard file, which is also useful for malleable irons and mild steels. The file may be advantageously replaced, as regards rapidity, by a drilling or planing machine if worked slowly so as not to heat the tool, which should have a blunt edge, especially if the metal be at all hard. Hardened steels, which are very difficult to work with the file or drill, may be softened by being raised to a red heat provided they be kept out of contact with the air—liable to lower their carbon content—and this may be effected by heating the part in a porcelain crucible placed inside another of clay, having pieces of coal between them, although such an operation modifies the chemical condition of the carbon. In the case of unhardened or annealed steels, powder or thin borings may be obtained by means of a file or blunt drill made of very hard steel.

QUERIES.

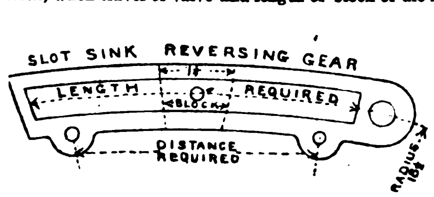
[96462.]—**Wimshurst.**—I have been constructing an eight-plate Wimhurst machine, as described in J. Gray's book on "Electrical Influence Machines." Beyond the plates there is no novelty in it. The construction of the plates is, I believe, original, and was suggested by a friend on hearing I was about to build a machine. They are made up of sheets of paper of the required diameter, boiled in paraffin wax, and a sufficient number of them compressed together to make a solid plate. This process makes a very rigid plate of the highest insulation, has no liability to break like glass or deteriorating like ebonite. For the same thickness it is more rigid than ebonite. The sectors are waxed on the plates, a groove afterwards being cut where the neutralising brushes run. I have been very particular in details, but cannot get the faintest suspicion of electrification from the machine. I have tried giving the plates an initial charge, without effect. I cannot see why the plates as constructed should not be an improvement on glass, especially as the sectors are almost completely covered with paraffin wax. I have tried to work it as a two-plate machine, with adjustable neutralising rods, but without success. I should feel much obliged if Mr. Wimshurst or Mr. Bottone would suggest to me where I am at fault, or give any reason why the paraffin plates should not work.—G. GREENHAM.

[96463.]—**Hovis Bread.**—Can anyone tell me what "Hovis" bread is made of, and how the material is prepared? Is it easy of digestion, and more nourishing than ordinary bread?—G. C.

[96464.]—**Great Laxey Waterwheel, Isle of Man.**—Can anyone say who designed and erected this great wheel, which is 72½ft. in diameter and 6ft. in width? It is an "overshot," and the water, conveyed in pipes from high-level reservoirs, ascends through a circular pillar directly behind the wheel, and is then led over the top of the wheel—an almost unique arrangement, as I should think. Power developed, about 150H.P.—N.

[96465.]—**Telephone.**—Will any reader kindly give me details, &c., of a simple telephone receiver and transmitter to work at about one mile, or particulars where I can get full instructions?—GOSSIP.

[96466.]—**Length of Slot.**—Would any reader please tell me how to work out the length of slot in link? Also to get distance between centres of eccentric rod ends, as per sketch, when travel of valve and length of block or die is



given? Example: Travel of valve, 1¾; length of block or die, 1¼; radius of centre of link, 18½.—ROBERT CRAWFORD.

[96467.]—**Inclination of the Pole.**—Will "F.R.A.S." kindly say what is the generally-accepted explanation of the inclination of the poles of the planets and their satellites? I cannot find this in Lardner, Herschel, Gregory, or Lockyer, and may we hope for his opinion on the monkey puzzle, which has excited more than an ordinary interest, because of its relationship with the lunar question probably?—J. R. J.

[96468.]—**Filling for Wood.**—Can anyone tell me by what process the German joiners fill up the end of the grain of wood? Their finish on the end of the grain is as good as with the grain.—HERBERT STONE.

[96469.]—**Indiarubber Stamps.**—Can any reader give me the following details of process for making indiarubber stamps—component parts of mixtures and temperature for working same?—G. A. L.

[96470.]—**Friction of Water in Pipes.**—What is understood by the expression "head in feet lost in passing a given quantity of water per minute through 100ft. of pipe"? A table accompanying this gives against 500 gallons and a pipe of 8in. inside diameter, 1·04ft. Does this mean that if my pipe or main is 27,000ft. in length (a project in actual contemplation), the frictional resistance to the flowing water, apart from any hydrostatic pressure, would be such as to increase the resistance equal to a column of water 280·8ft. in vertical height, for $\frac{27,000 \times 1{\cdot}04}{100} = 280{\cdot}8$. As I have, in addition, to deliver the water to a height of 410ft. above the pump, does this mean that the total resistance equals a vertical column of 410ft. plus 280·8ft. = 690·8ft.? Can you favour me with a rule for estimating this friction, and say if there are any other resistances than this, or hydrostatic pressure to be taken into account? To what extent do bends affect it?—M.

[96471.]—**Loan Amortisation.**—Are there any loan institutions existing in England which lend money at rates starting from 4 per cent. interest, and yet are repaid by a part of the interest being devoted to the paying back of the capital till annulled? Thus: say £1,000 is borrowed at 4½ per cent. interest, the capital to be paid back out of the interest in 44 years by a sum amounting to £1,967·57, whereas in the ordinary way the borrower would have paid £1,980 in interest alone, and still be indebted the amount of the original sum borrowed, or £1,000. This seems a very advantageous arrangement for borrowers, as in this way a debt extinguishes itself (against regular payment of the stipulated interest) instead of existing as an incubus upon the borrower. In addition to crediting the amortisation interest, there is a further credit at the rate of 3½ per annum on the part of the capital annulled each year by the amortisation interest, amounting in the second year to £0·35, and in the last or forty-fourth year to £31·47; the capital dwindling down from £1,000 to £31·47 in the forty-fourth year, and which is covered, as shown, by the credited interest on the paid-back or annulled portion of the capital, leaving only a balance of £1 10 to be paid by the borrower at the prearranged rate of interest in order to be quit of his liabilities. At 4 per cent. interest, ½ per cent. is devoted to amortisation.—X.

[96472.]—**Soret's Fluorescent Eyepiece.**—Can any correspondent give me details of construction and use, or refer me to any readily accessible book?—C. R. L.

[96473.]—**Hand Camera Shutter.**—Kindly give details to make a hand-camera shutter, either pneumatic or otherwise, for an Adams's Yalus twin lens. Kindly give a sketch.—YALUS.

[99474.]—**Colouring Rubber or Vulcanite.**—The platen roller of typewriters when received from the factory are of a nice, soft, white appearance; but after a few weeks' use this disappears. I have a few rollers slightly damaged, and would feel obliged if any reader will tell me how I can produce its finished appearance. The rollers I refer to are made of rubber, while others are of vulcanite.—COLONIST.

[96475.]—**Reflector.**—Will be obliged for design of simple stand for 10ft. focus reflector. There is a stand illustrated in Vol. X, by "Foreigner," which is said to give equatorial; but details are not shown.—H. N.

[96476.]—**Absolute Temperature.**—What is the meaning of "absolute temperature"? Also, "what is supposed to be the temperature of stellar space"? Also, "the boiling point of liquid hydrogen"? and the "zero of temperature"?—B. L.

[96477.]—**Old Coins.**—I have a number of old copper coins laying on velvet in a coin cabinet, and on looking over them I find that most of them are incrusted in places with verdigris. Can any reader kindly suggest a method for removing it without defacing the coins.—A. TURNER.

[96478.]—**Poultry.**—Will any reader kindly tell me the reason why fowls pull out and eat each other's feathers, as I have about twenty of last year's pullets who have almost completely stripped each other of their plumage?—A. TURNER.

[96479.]—**Bunsen Burner.**—Could any reader say what is the advantage of a Bunsen burner? Say you had a ½in. pipe without a Bunsen leading to an ordinary range oven, and one with the same size of pipe but fitted with a Bunsen, which would give the most heat, and which burn the most gas? And would a Bunsen burn well with, say, $^1/_{16}$in. hole, discharging into a $^7/_{16}$in. tube, with a piece cut out of tube, say ½in. square for the air, and eighteen holes for the flame each $^1/_{16}$in. diameter?—NOT SURE.

[96480.]—**Preserving Flying-Fish.**—Can any reader inform me of a way of preserving flying-fish, so that the skin retains some of its colour and smoothness?—D. COBWEN.

[96481.]—**To Mr. Bottone.**—I have made a small dynamo (Siemens H pattern) from your castings. I cannot get it to produce any current, but it will work as a motor. The only thing that can be wrong is the connection of the magnet and armature wires. Does it matter which are connected to which? If so, why?—D. COBWEN.

[96482.]—**Insects in Floor.**—I have a dark room in my house in the basement, the flooring of it having a great many small holes in it the size of a pin's head. We are much troubled with a great many small brown insects coming up through them. Could any of your readers tell me how to exterminate them or keep them from increasing?—A. J. SCOTT.

[96483.]—**Speed for Waterwheels.**—Can any reader kindly give a simple rule for calculating the horsepower of waterwheels, and say the usual number of revolutions per minute they should be driven?—J. PEARCE.

[96484.]—**Cubical Contents.**—An embankment on level ground is 100 yards long, 17ft. on top, and 10ft. high, the sides having a batter of 1 in 3. Calculate its cubical contents.—ENQUIRER.

[96485.]—**Humane.**—Re the article on "Human Species," will Mr. Blackwood or some other reader please say whether the offspring of a woman whose mother is a deaf mute are likely to be affected or not, the mother and father of the child not being affected.—ANXIOUS.

[96486.]—**Loune's Vacuum Engine.**—Can any of "ours" give sections, &c., of above?—E. R. DALE.

[96487.]—**Torpedo Boat Destroyer.**—Could any reader kindly tell me where I could find drawings of sections of a torpedo boat destroyer, as I wish to build a model 3ft. 6in. long, but am at a loss for correct design of hull?—T. J. P.

[96488.]—**Pitch of Worm.**—Will some of my fellow turners give me some information of the following? I have seen small worms coming into shop to have new ones made in place; they are about 1½in. diam. off some lubricators. Would someone inform me the way to get the pitch of them? The wheel is usually sent in with them. The way I have seen them done is to rig up some wheels something near and keep changing wheels till they get right pitch. Surely there is some better way than this to get wheels and pitch?—TURNER.

[96489.]—**Wimshurst Experiments.**—How should I attach Leyden jars and other apparatus to discharging rods of 4-plate Wimshurst in case? When I connect with copper wire the electricity appears to escape, as I get very little at the jars. Also, how can I make pith balls and figures dance? I have a bell jar standing on tin bottom connected by chain to earth, with ½in. brass rod passing through cork, with brass ball at each end of rod. I get a spark between ball inside jar and the tin bottom, but the figures do not move. There appears to be no provision on Wimshurst for attachment of wires except by twisting wire round the rods.—H. H.

[96490.]—**Lantern Query.**—Can any of your readers tell me whether it is possible to get a good 10ft. picture from a Russian iron magic-lantern, costing £4 4s., fitted with a Stocks patent petroleum lamp? And if so, what would be the best foci of front lenses, and best distance from the screen? I have such a lantern; it has 7in. equifocus, and I cannot get a good picture larger than 4ft. 6in. at a distance of 16ft. from screen.—BEGINNER.

[96491.]—**Electrical.**—Could one of your electrical correspondents give me a description, and, if possible, a diagram of the working of Wright's patent rebate indicator, used by electricity supply companies who charge for current on the Brighton system? I cannot find any reference to it in any book on electric lighting, &c., I have seen, or in back numbers of the "E.M."—S. B. G.

[96492.]—**Motor Cycles.**—Is it possible for the writer on the above interesting subjects, or "Monty," to describe the two-speed gear which is used in connection with the motor tandem quadricycle now being sold by Brown Bros.? I should imagine a clear description of this would be highly esteemed by readers on motor cycles.—INTERESTED.

[96493.]—**Parachute.**—Would any correspondent give me the following particulars? The ratio between the supporting area of parachute and the weight supported, and the ratio between the size of the air-hole and the size of parachute.—PNEUMO.

[96494.]—**Wireless Telegraphy.**—Could an A B C apparatus be operated without connecting wires on the Marconi system?—OPTICAL L.

[96495.]—**Oilstone.**—Can any reader tell me how to repair 11in. Turkey stone (broken through in two places), so as to avoid chisels catching when rubbing up?—CEMENT.

[96496.]—**Canary Complaints.**—He is a "mule," a cross with a linnet. Every few days he drops off his perch, huddles himself in a corner, evidently in great distress, and looking for all the world as if he were dying. In a few hours he comes round, gets on his perch, and hops and chirps about as happy as an Outlander in possession of the franchise. When he came into my possession he had a ring bare of feathers round his neck, probably caused by overstraining through the holes to reach his food, when irregularly attended. This baldness has gradually spread over his head and chest. His habits are regular; fed every day, cleaned out twice a week; but does not improve. Any information on these two complaints will greatly oblige.—PRETORIA.

[96497.]—**Magnetic Effects.**—I believe that the electrical resistance of some metals becomes greater when under the influence of a magnetic field. Can you inform me (1) in what metal is this most marked? (2) In what proportion does the resistance vary with the strength of the field? (3) What is its specific resistance under ordinary circumstances? (4) Where can it be procured? I should be much obliged for any information on the subject.—H. E. DONNITHORNE.

[96498.]—**Boat.**—I intend having 18ft. sailing-boat built, with centre-board, and fitting same with 2H.P. petrol. motor. Have any of our readers any experience to offer? Should be glad of short specification. Also any books that would assist in this matter.—AERIAN.

[96499.]—**English Lever.**—I have an English lever watch, a fairly good timekeeper, but not just up to what I would like. In comparing its timekeeping with a regulator clock, I find it does not gain or lose more than a minute per week, but then it sometimes varies as much as that in one day; there is a want of steadiness. Would some reader let me know if Swiss-made watches are good timekeepers?—P. DEWAR.

[96500.]—**Inspector of Weights and Measures.**—Can any of your readers tell me the time it takes to qualify for an inspector of weights and measures? What are the prospects of obtaining a situation when qualified?—INDECISION.

[96501.]—**Oil and Gas-Engines.**—I think of building a small stationary oil-engine, and shall be glad to know if the dimensions given for the motor-car engine now appearing in the ENGLISH MECHANIC would be suitable for a stationary engine, and if not, what alterations would be required to be made.—LEARNER.

[96502.]—**Cement for Cork.**—I wish to stick some cork chips, &c., so that I can fill up a boot for cripple. I cannot get one piece large enough, and I want to mix up a quantity, put in, and cut room for foot after. Have tried ordinary glue, but it will not act.—G. W. B.

[96503.]—**Shire.**—What is the origin of the term shire as tacked on to the names of counties? "Shire" itself is, I suppose, the Anglo-Saxon "scir," a division; but why do some counties take "shire" as part of their designation—e.g., Gloucestershire, Wiltshire, Devonshire, Hampshire? A fanciful explanation is that the county only adds shire to its name when the county town has the same appellation; but that will not do, as will be seen in one of the above examples; and on the other side there is Durham—I do not think I ever heard of Durhamshire. I presume the use is only arbitrary, and mere usage has made the terms correct. In legal documents the usual phrase is the county of—so and so, not shire.—ARCHAIC.

A VERY interesting piece of work has recently been accomplished at Jersey City Terminus of the Pennsylvania Railroad Company. The necessity having arisen for increasing the length of the train shed, which is covered by an arched roof of 253ft. span, it was determined to move back the two end bays bodily a distance of 125ft. towards the river, the extension to the roof being erected in the space thus provided. The weight shifted was 300 tons. The arches, as already stated, were of 253ft. span, and the centre height was 92ft. 3½in. To prevent the arches spreading during the work of renewal, the springings had at the outset to be tied together by 2in. tie-rods. The ribs were then jacked up clear of their foundations, and the weight transferred to nests of rollers running on a double track laid with 85lb. rails. To prevent the arches overturning during the process of removal, a large A-frame of timer was secured to the structure near the crown. The legs of the A-frame just cleared the platform when the arches were upright, but prevented any dangerous tilt occurring in either direction. During removal the arches were shifted at the rate of 5ft. to 10ft. a minute, and the work was accomplished without any accident to men or material.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, August 16, and unacknowledged elsewhere :—

Joseph Collinson.—Householder.—Enquirer.—G. W. H.—M. C. F.—Mabel.—C. J. F.—D. C. Baly.—Denture.—J. W.—T. E. Espin.—R. T.—W. Ewart Gibson.—A Fellow of the Royal Astronomical Society.—Meteor.—Fish Plate.—J. Lane.

Cosmo.—Yes. We can send the set of "best books" to any address abroad. We will pack them in a strong case free of charge, and send them by any agency you direct. We cannot tell you exactly what the freight will be—probably three or four shillings; but you can pay that on delivery at your end.

Scorpio.—We are not going to reopen the whole question of vaccination. We said so a fortnight ago. We ourselves regard the utter futility of vaccination as absolutely demonstrated, and that to discuss the general question is lost labour. We thought the special point raised a fortnight ago worth discussing, apart from the main issue.

Benj. Ruddlesden.—Presumably the powder you send is that described in reply 96336, "Chimney Cleaners," p. 538, July 28 last. The powder is packed in the way described probably because the makers find it the best method. The reply referred to no doubt gives all the available information; but we cannot make analyses and give particulars as to the method of preparation of such articles.

J. H. Perkins.—Same question, in principle, as that about the top of the wheel moving faster than the bottom. In an instantaneous photograph of a bicycle in motion the upper spokes are indistinct because they are moving faster across the line of sight than those at the bottom. If the top part of a wheel travelling along a road did not move faster through space than the bottom, at any given moment, how would the wheel advance along the road? See the indices of back volumes, or refer to any work which describes the cycloid.

Jas. Edwards.—The query was noticed (in a way) on p. 493, when it was suggested that a sketch would help to elucidate. Of course, it has not been entered in the list of "Unanswered."

T. V. M.—See Hints to Correspondents No. 4. Any metal shop can supply aluminium in sheet or ingot. Surely there is a shop in Leicester where it is sold. As to joining it together, see the many replies in back numbers on soldering aluminium.

T. Erickson.—There must be some mistake. Never heard of a machine moved by dynamite. There are electro-motors for bicycles—but Cui bono?

Moto.—"Auto-Cars," by D. Farman, published by Whittaker and Co., will suit; or if you read French, "Voitures Automobiles," published by E. Bernard et Cie., Quai des Grands-Augustins, Paris. Do not know of any American "journals" specially devoted to motor-cars.

Know Nothing.—If you can refer to, say, the last six volumes, you will find an answer to your question given many times over, probably even to the exact size of your dynamo.

Steam.—Please see Hints to Correspondents, No. 4. Any of our advertisers who deal in boiler fittings can supply them.

Ivanhoe.—Can only refer you to some textbook on magnetism; but to the first question the answer is No.

W. Teago.—Platinum is a white metal about as hard as copper, as ductile as iron, but inferior in tenacity. It is very refractory, and can be melted only by the oxy-hydrogen furnace or blowpipe and the electric furnace. Acids have little, if any, effect upon it, and it does not oxidise in the air at any temperature; but it is corroded when heated to redness in the air in contact with caustic alkalies. You can form a rough idea of whether the piece of metal is platinum by comparing its weight (it is heavy) with that of other metals; but test it with acids, and then with an ordinary blowpipe.

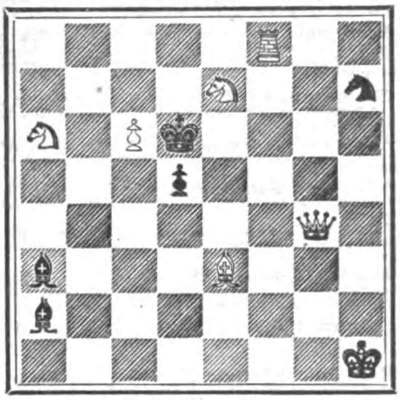
D. H.—Cases like these are much too serious for amateur advice, given in utter ignorance of the habits and past history of your friend. The probability is that he inherits a scrofulous taint, or that he is suffering from wrong living, and no one but a skilled medical man can help him. It can, at any rate, do him no harm to read the "Medical Column" in the *Weekly Times and Echo*, edited by Dr. Allinson, and live for a few months as there directed.

CHESS.

All communications for this column to be addressed to The Chess Editor, at the Office, 332, Strand.

PROBLEM No. 1688.—By F. Healey.

Black. [5 pieces.



White. [7 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Aug.* 28.)

Solution of Problem No. 1686.—By H. Otten.

Key-move, Kt-Q 3.

NOTICES TO CORRESPONDENTS.

Problem No. 1686.—Correct solutions have been received from Mahtale, A. Tupman, Richard Inwards, Quizeo, T. Clarke, Rev. Dr. Quilter, Hampstead Heathen, Whin Hurst, F. B. (Oldham), J. Mason, Carte-Blanche.

P. Laubach.—Correct solution received. Regret that space is too limited ror criticism.

USEFUL AND SCIENTIFIC NOTES.

The British Fire Prevention Committee have recently carried out a number of experiments on "non-flammable" wood, wire glass, slag wool, and the like. The object of the test with "non-inflammable" wood was to ascertain in a reliable and independent manner whether thin boards (¼in. rebated) would sustain or spread flame when in contact with fire of such high temperatures as 1,000° Fahr., for terms of five, ten, and fifteen minutes respectively. The wire glass both in skylights and windows was to show its resistance under a fierce fire increasing to a temperature of 1,000° Fahr., water being applied before and after the tests, which lasted 30 and 45 minutes respectively. The slag-wool ceiling was to withstand a fire increasing to a temperature of 2,000° Fahr. for an hour, followed by the application of water. The reports embodying the important results of these tests will be issued in due course.

Rubber Tires.—Some important observations concerning the action of the various gases upon caoutchouc and upon rubber tires have been made recently by M. d'Arsonval. If bits of caoutchouc tubing are placed in gaseous carbonic acid, under a pressure varying from 1 to 50 atmospheres, the substance increases considerably in volume and absorbs large quantities of the gas—so much so, that it often acquires ten or twelve times its original volume. At the same time, the caoutchouc becomes more gelatinous and less elastic. On leaving it exposed to the air, the carbonic acid disengages itself in bubbles, making a crisp sound on leaving, and in about an hour's time the caoutchouc has resumed its original aspect and properties. When carbonic acid is simply inclosed in a caoutchouc bag, it passes out rapidly through its walls. Oxygen does the same, though much more slowly. Here lies the explanation of the gradual deflating of pneumatic tires, says the *Electrician*. Newly-inflated tires deflate much more rapidly than those on which the pump has often been used, since the latter contain almost nothing but nitrogen, the oxygen having passed out through the tire without waiting for a puncture. The oxygen may be collected on the other side of a thin rubber partition. When tires are to remain inflated for a great length of time, they should be filled with nitrogen.

The Tonic Properties of Sea Air.—Considerable speculation has from time to time been made as to what causes the invigorating and tonic properties of a seabreeze. Ozone is very commonly accepted as at any rate an important factor in this connection, since it is invariably present in air that has been in contact with sea-water, and especially agitated sea-water, and to a smaller extent in the air of the country; but it rarely occurs in the air of towns and crowded places. Ozone, however—and with it probably traces of hydrogen peroxide—is undoubtedly formed by air skimming over the surface of fresh water, and hence the breezes coming over the lochs in Scotland and large lakes and rivers in other places become ozonised and bracing. The Briton has an instinctive fondness for procuring his change or spending his holiday down by the water side, be it sea, lake, or river, probably because he finds, though he does not know exactly why, that the air of water-side places does him more good than the air of the country, where there are trees and beauties of landscape, but no large tract of water. The freshness of the early morning air is due most probably to the formation of dew on the previous night, the transition from the vaporous to the liquid state causing ozonisation of the air with which the condensed watery particles come into intimate contact. This freshness disappears as the day wears on, because of the readiness with which ozone is destroyed by organised and organic substances. The exhilarating effect of a sea-breeze may, however, be ascribed to other bodies which are foreign to inland air. The sea air contains a traceable amount of salt and iodides, attaining a maximum of 0·022 gramme per litre, or about one and a half grains per gallon. These mineral ingredients derived from the sea doubtless accentuate the tonic action of sea air, and further it is probable that ozone interacting with chlorides and iodides would lead to traces of chlorine and iodine being present. Many persons describe the smell of strong sea air as iodous or chlorous, and it has even been said that the starch used in face-powders turns blue at the seaside on account of the iodine in the air, forming blue iodide of starch. If that be so the blue and haggard appearance characteristic of many faces exposed to a strongly salt-impregnated breeze would find an interesting, but perhaps embarrassing, explanation.—*The Lancet.*

An American electrical paper recently instituted a competition for a name for an electrically-propelled carriage. About four hundred names were suggested, from which we have selected the following :—Accelawatt, Equine-nit, Bacrotom, Automo, Aut, Faraday, Autopropelectric, Electragon, Moto, Trolley-ho, Locomobile, Telecar, Electrapel, Autovolt, Autogo, Elecar, Pacolet, Franklin, Automote, Chevaless, Moby, Plantemobile, Electrola, Antihorse, Voltcar, Quatrecycle, Odomotor, Autema. "Electromobile" was the name adjudged the most suitable.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent One Month before expiration, in order to give them time to forward fresh remittance before subscription expires.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

"English Mechanic," 517 numbers to date, clean and perfect. Offer wanted.—SCHOFIELD and HILTON, Diggle, Oldham.

Wanted, Cash, Photographic Apparatus, Tools, Engine or Dynamo for goods advertised below. — 86, Greyhound-road, Tottenham.

Globe **Typewriter**, cost £3; 4-volt, 30-hour Accumulator; and a £6 jewelled Astatic Galvanometer.—Above.

Gent's **Safety**, Eadie fittings. Exchange 5in. centre lathe.—HICKTON, 73, Bow Common-lane, Bromley, London, E.

4in. **Spark Coil**, £6. Orguinette, seventeen airs, 12s. Offers.—CLIFFORD, 127, Upper Dorset-street, Dublin.

Spirit Motor, new, 3H.P., steel cylinder, with water jacket, high compression, complete with carburettor and ignition tube, will bear closest inspection, £25, worth £35. Would exchange for Stockport or Crossley Gas-engine.—12, Edith-road, London, S.E.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of Screws, Bolts, and Nuts for model work, drawn to actual size, sent on receipt of stamp. —MORRIS COHEN, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—MORRIS COHEN, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—CLEGG, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—JARRATT, Queen-street, Leicester.

How to Make Your Poultry Pay the Rent, and increase your income. Astonishingly marvellous, but true. Easily done. 1s. 6d.—GRAVES, Stonebridge Park, London, N.W.

Carving. — Brass, Iron, Burnt Wood, Bamboo, Leather, Fretwork, and Picture Framing. Catalogue free.—HARGREAVES, Settle, Yorks.

Inventions Protected, £3 inclusive. Designs registered, 30s.—BROMHEAD and Co., Registered Patent Agents, 33, Cannon-street, London. Established 25 years. Send for list.

Sidereal Time Indicator, invaluable to all users of equatorials, with complete directions, 21s. post free.—Below.

Astro-Photographic Apparatus, does really good work, 15s. post free.—HORNE and THORNTHWAITE, 416, Strand, London.

Rubber Outer Covers, average 16ozs., Para rubber 5s. each.—FRANKLANDS.

Rubber Outer Covers, 3s. 6d. each, 36s. per dozen. —FRANKLANDS.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—FRANKLANDS.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—FRANKLANDS.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight., 2s. each.; 21s. per dozen.—FRANKLANDS.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 2s. 6d. each.—FRANKLANDS.

Detachable Outer Covers, licensed, 12s. 6d. each. —FRANKLANDS.

Saddles.—A clearing line in ladies' and gents' saddles, 2s. 6d. each, 24s. per dozen.—FRANKLANDS.

Inflators, 18in., 1s. 6d. each, 15s. dozen. — FRANKLANDS.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 5s. per dozen.—FRANKLANDS.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—FRANKLANDS.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—FRANKLANDS.

Spanners, nickel, usual price, 13s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—FRANKLANDS.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—FRANKLANDS, Astley Gate, Blackburn.

Books.—All out-of-print books speedily procured, any subject. State wants.—BAKER'S GREAT BOOKSHOP, Birmingham.

Rubber Outer Covers, 3s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—PEMBERTON.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—PEMBERTON.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—PEMBERTON.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—PEMBERTON and Co., 1, Cardwell-place, Blackburn.

Acetylene. — Send for particulars of the patent "Incanto" Generators, Purifiers, Burners, Carbide, &c.—THORN and HODDLE, 1, Tothill-street, Westminster. Works, Harris-street, Camberwell.

Photography.—Watkins' Actinometer makes exposure certain, new watch shape, 3s. 6d.—FIELDS, 142, Suffolk-street, Birmingham.

"Demon" Gas-Engines, Otto principle, awarded prize medal, guaranteed efficiency. All sizes from ½B.H.P. upwards. —Below.

"Demon" Gas-Engines, ½B.H.P., £9; ¾B.H.P., £12; 1B.H.P., £15; 1½B.H.P., £18; 2B.H.P., £23. Wonderful value. —Below.

"Demon" Gas and Oil-Engines, high-class, popular prices. Particulars free.—PASLEY and Co., Sherborne, Dorset.

50,000 Choicest Microscopical Objects.— Bargains. Catalogues free. Microscopes, cabinets. Collections purchased.—SUTER, 10, Highweek-road, Tottenham.

Economic Electric Co.—New Illustrated List: Pocket Accumulators, Accumulator Parts, Electric Jewelry, Dynamos, Motors, Batteries, Coils.

Economic Electric Co.—New List Electric and Scientific Novelties, 2d.—118, High Cross-road, Tottenham, London.

Have You Sent Yet

For Our "Twenty-five Best Books"?

They are Good Value for the Money.

They are Now Ready, and we shall Not REPRINT.

Fifty Shillingsworth of Books and a Half-guinea Bookcase for 30s.

For Full Particulars see Illustrated Advertisement on another page.

Best Assortment of High-class Popular Literature ever obtained at the price.

A Splendid Present to a Friend, or a Village Club, or Working Men's Institute.

Guaranteed to give Satisfaction. Well printed, well selected, well bound. Price, all complete, only 30s.

Send Cheque or P.O.O. for 30s. at once to the Publisher of the ENGLISH MECHANIC, 332, Strand, W.C.

Delivered in London Free. Country orders sent carefully packed, by rail, carriage forward. Please write address plainly.

Send at Once to Save Disappointment. Price for the set complete, in oak bookcase, 30s. Obtainable only at the Office of the ENGLISH MECHANIC, 332, Strand, W.C.

Blackbeetles, Cockroaches can only be exterminated by UNION COCKROACH PASTE. Guaranteed by E. Howarth, F.Z.S., who described its unfailing efficacy in "Ours" of July 27, 1898, where the Editor strongly recommends it. In tins, 1s. 3d., 2s. 3d., 4s. 6d., from J. P. HEWITT, Chemist, 66, Division-street, Sheffield.

Brass and Gunmetal Castings of finest quality. Prices on application.—DANIEL YOUNG, Witney, Oxfordshire.

Nursery Hair Lotion, for children attending school, &c. Certain cure guaranteed. 1s. pint tin, free.—Below.

Lubricating Oils, Varnishes, Polishes, Stains, Colours, Paints, Gasoline, Kerosene, Naphthas, very cheap.—JONES COMPANY, Bethnal Green.

CIGARS

The BEST THAT MONEY CAN BUY, and the price is only

TWOPENCE

If he does not keep them, he does not know his business. But don't be disappointed; send 8s. 4d. for a Box of 50, which will be forwarded you from the office free by post.

BEAR IN MIND these Cigars are not rubbish, but are made of first-class tobacco, and have been pronounced by connoisseurs equal to those usually sold at 6d. or 9d. each.

Address "Cigar Dept.,"
"WEEKLY TIMES and ECHO,"
332, Strand, London, W.C.

Motor Spare Parts and Accessories of all descriptions.—Below.

Motor Tricycle, 1H.P. £25., 1¾H.P. £50. Boiler Car, 3H.P. £75. 2¾H.P. Engines, with carburettor and fittings, £28.

Send for Our Illustrated Catalogue.—THE SOUTHERN MOTOR CAR Co., 59, Brixton-road, London.

Paraffin Oil Launch, small, fast, nearly new, in grand condition, for immediate disposal. Also small two-cylinder Paraffin Launch Engine.—HILLIER, Romsey, Hampshire.

Practical Milling in the Lathe has been reduced to its simplest possible form by our Simplicity Milling Attachment. Send stamp for list to—SMART and Co., Erith, Kent.

Gas and Steam Engines, Dynamos, Motors, Sets of Castings. Machine work done for amateurs; any description.— Below.

½-horse **Gas-Engine**, £14, five-light Dynamos, £7, Photos. 3d.—H. and A. THORNTON, Eddercliffe, Cleckheaton.

F. C. Allsop, Manufacturing Electrician, 126, Queen Victoria-street, London. The leading house for all electrical goods.

F. C. Allsop's Electric Bell Catalogue (Section B), post free 6d. Electric bells, indicators, pushes, batteries.

F. C. Allsop's Electric Light Catalogue (Section L), post freee 6d. Cables, switches, accumulators, dynamos, motors, &c.

F. C. Allsop's Telephone Catalogue (Section T), post free 6d. Hunnings microphones, receivers, magneto switch bells, &c.

F. C. Allsop's Induction Coil Catalogue (Section M), post free 6d. Spark coils, medical coils, X-ray apparatus.

F. C. Allsop's Electrical Handbooks, over 80,000 copies sold. "Practical Electric Bell Fitting" (7th edition), post free 3s. 6d.

F. C. Allsop's Electrical Handbooks. "Practical Electric Light Fitting," 5s. "Telephones: Construction and Fitting," 3s. 6d. "Induction Coils," 3s. 6d.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—BUTLER BROS., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—BUTLER.

"Spesco" Belting Syrup, prevents slipping and keeps belts in good condition, 1lb. sample tin, post free, one shilling. SPESCO Ltd., Suffolk-place, Bermondsey, London.

W. Probert and Son, Brassfounders, Whateley-road, Handsworth, Birmingham,

Manufacture Brass Fittings in quantity to sample or drawing.

Brass Tubes, Sheet, Rods, Wire or Strip.

Brass Castings to Pattern.

W. Probert and Son, Whateley-road, Handsworth, Birmingham. Works: Tower-road, Aston.

Model Boiler, 13in tubular, nearly new, tested 50lb., brass mountings, 17s.—51, Winchester-road, Romsey.

Balls, in brass or gunmetal, for valves, steel, ¼in., 3-16in., 1s. per gross; ⅜in., 1s. 6d.

Screws for All Purposes. Screwing and screw-cutting for the Trade at reasonable prices. Patterns made.

Castings, iron, brass, gunmetal, steel, or malleable iron. Forgings made to order from 6d. per lb.

All Kinds of Engines and Machinery repaired promptly.—SCREW, BOLT, and ENGINEERING Co., Penn street, Wolverhampton.

Inventions Protected and Sold. Inventors assisted. Advice free.—ELT and Co., 43, Southampton-buildings, Holborn, London.

Simplex Typewriter, 14s. 6d., delivered. Thousands in use. Illustrated particulars free.—ATKINSON and Co., Harehills-avenue, Leeds.

"B" Gas and Oil-Engines. Supplied the world over. Particulars stamp.—A. and S. BARKER, Engineers, Leyton, E.

Launch Oil Engines a Speciality. New designs. High speed. Very reliable.—A. and S. BARKER, Engineers, Leyton, E.

"B" Oil-Engine Castings and Forgings. Easy to make; no complicated parts; very reliable.—BARKERS, Leyton.

"B" Oil and Gas-Engines are fitted with silent gears, sensitive governors, adjustable bearings.—BARKERS, Leyton.

Original Testimonials can be seen at any time, together with English and Colonial Press opinions.—BARKER.

Wheel-Cutting.—Spur, bevel, mitre, or spiral gear, in all metals, to any pitch.—MOTOGEAR, below.

Differential and Spur Gearing as illustrated in "E. M." Motor tricycles. Special prices.—MOTOGEAR, below.

Accurate Screwcutting and Fine Turning a speciality.—THE MOTOGEAR ENGINEERING Co, 78, Queen Victoria street, E.C.

"Gem" Gas-Engines.—Still simplest and best for small powers.—MOTOGEAR Co., below.

"Gem" Gas-Engine Castings. — Easiest to make up.—MOTOGEAR ENGINEERING Co., 78, Queen Victoria-street, London.

"Gem" Oil-Engines.—New designs for launches and vehicles, &c.—MOTOGEAR Co., above.

Sample 100 Billheads, Memorandums, or Cards, post free, 1s. 3d.—YOUNG, 57, Leyton Park-road, Leyton.

Motor-Car Engines to any specifications from ½ to 6B.H.P.—H. JONES.

Gas-Engines, Otto cycle, horizontal, ½B.H.P., £12. 1½B.H.P., £20. Descriptive list stamp.—H. JONES.

Oil-Engines, horizontal, ½B.H.P., £13 10s.; 1½B.H.P., £22; extremely simple.—H JONES.

Dynamos, vertical drum, 4-lights, £3 10s.; 6-lights, £5; 8-lights, £6 10s.; 10-lights, £8.—H. JONES.

Dynamos from 30s. Lighting, plating, storing, &c. —H. JONES, 14, High-street, Lambeth, S.E.

Watches, Clocks, Jewelry, Musical Boxes, Novelties. Dealers supplied at rockbottom trade prices for cash. Cheapest house in England. Lists on application. Gentleman's crystal face keyless nickel silver, 2s. 9d.; not less than three will be sent.—WOOLANDER and Co., 90, 91, Queen-street, London, E.C. Agents wanted. Mention Paper.

Paraffin Wickless Stoves burn without smoke or smell, safe and reliable, very useful in household.—Below.

Paraffin Wickless Stoves, powerful and easily managed, splendid thing for yachting, boating, camping-out.— Below.

Paraffin Blowlamps for Plumbers, Painters, Brazing, and Ignition Tubes. Illustrated lists, stamp.—HICKS, Tool Merchant, Maldon, Essex.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, AUGUST 25, 1899.

MOTOR CYCLES.—XIV.

A LUG must be brazed to the compression stay-tube which connects the bottom bracket to the bridge tube, to which the carburettor is to be bolted. Fig. 88 shows this lug with the carburettor and float-chamber indicated in position by dotted lines. The lug itself is to be cast in malleable iron. I have not dimensioned the facing to which the carburettor is fitted, except the thickness, as it is made the same size as the square facing on the bottom of the carburettor, as given in Figs. 35 and 38. A semicircular channel is cast across the face to accommodate the petrol supply-pipe leading from float-chamber to carburettor. It will be noted that the same studs which hold the float-chamber to the carburettor are also employed to secure these parts to the frame-lug. This view also shows how the exhaust branch pipe is secured to the coil in the bottom of the carburettor. Sufficient of the end of the copper coil is left to project ⅜in. through the boss. This is then to be screwed ⅛in. gas thread. The exhaust branch pipe is also screwed to match, and the joint between the two made by means of a socket and lock-nut, which must both be smeared with red-lead before screwing up. The outlet for the exhaust-branch at the other end of the coil is filed off flush with the boss.

In the side view of the lug in Fig. 88 I have not shown the float-chamber, to avoid confusion—it would show behind the lug in this view. The exact position of this lug on the compression stay-tube is of no great importance; but it must be sufficiently far back to miss the driving chain, which is easily arranged as the stay-tube runs upward at a fairly sharp angle. The postion will be better defined in a general arrangement, which will be found in my next.

Fig. 89 shows the handle-bar switch, used for cutting off the current when turning a sharp corner or applying the brake. Its parts are lettered as follows: A is the handle-bar tube, on to which is brazed the mild-steel collar B. This collar is ⅜in. wide and ¼in. thick. The extreme end of the tube is screwed any convenient thread, say 20 per inch, for a length of 5/16in. On to this thread the collar C is screwed, which prevents the handle-bar grip D from being displaced endwise. Inside the handle-bar is the rotating contact-plug E, which is secured to the handle-bar grip D by the two screws I, which pass through slots cut in the handle-bar tube. G is a block of insulating material, preferably vulcanised fibre, having secured to it two contact-strips F F. To these strips the wires of the primary circuit are secured by means of the two screws K, and between them the contact tongues of the plug E work. L shows the end of one of the four screws used to hold the insulating block in position. Some means must be provided whereby the rider will be able to tell if the switch is in the "off" or the "on" position, and to retain it in either position. This is conveniently done by means of the flat spring H, recessed into and fastened to the handle by the screw, the other end dropping into notches cut in the collar B.

Taking the switch in detail, the handle-bar grip comes first. This should be turned from any suitable material, such as horn, vulcanite, or even ivory, if the expense is not objected to, to the dimensions given in Fig. 90. Make the bore a nice fit to the handle-bar tube, which is to be of 1⅛in. diameter by No. 16 B W.G. Braze a collar on the handle-bar, Fig. 89 B, making the taper of its outer edge a continuation of the taper of

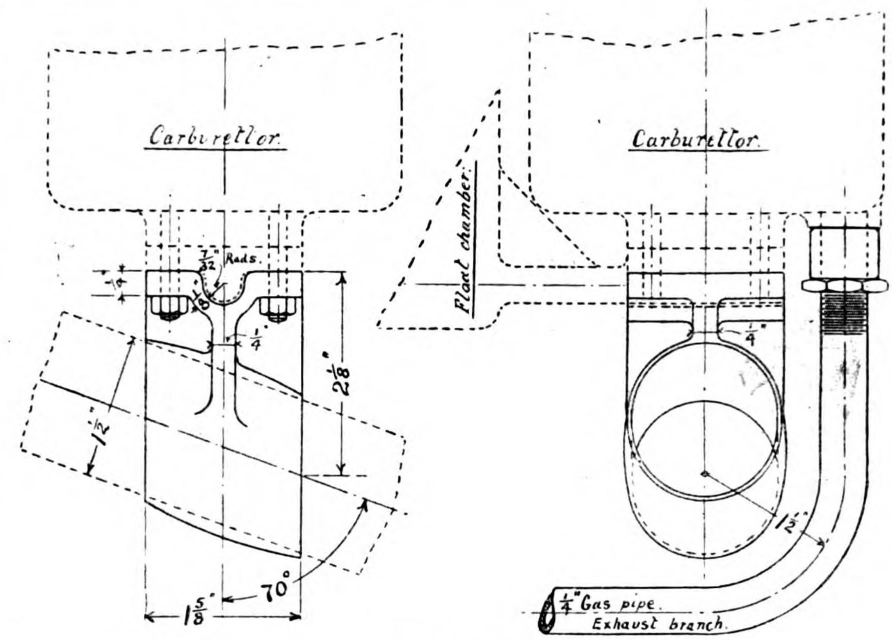

Fig. 88.

the horn handle. This is best made of mild steel, and should be turned to size and shape before brazing on. The insulating block is next turned up from a piece of vulcanised fibre rod to the sizes in Fig. 91. The dovetail grooves are to take the contact-strips, Fig. 92, which are of brass, bent and filed up to shape from 1/16in. plate. The narrow edge of the strip where the contact plug works should not be more than 3/32in. wide.

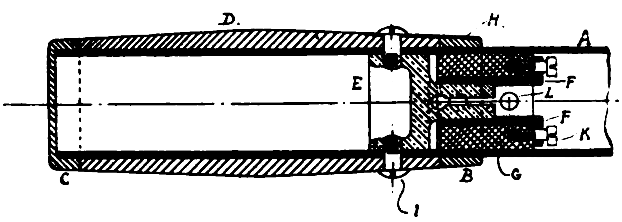

Fig. 89.

The strips should fit quite tightly into the grooves, and project very slightly into the bore of the insulating block, just sufficiently so to insure the contact-plug bearing on them, and making good contact. The back of the contact-strips need not be rounded. The contact-plug can be turned from brass rod or from a casting; but the drawn rod is preferable, as being more free from flaws and having more spring. Dimensions are to be taken from Fig. 93. The part of the plug which works in the insulating block is filed

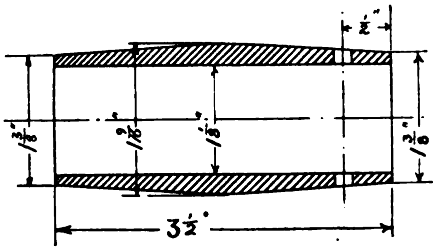

Fig. 90.

flat on both sides, leaving it 3/32in. wide for ⅜in. of its length. A rotary movement of the handle to the extent of ½in. will suffice to either turn on or cut off the current. To keep the handle in place, the cap, Fig. 94, is screwed on to the end of the handle-bar. It is made of mild steel, and the thread should fit tightly. When finished, it is to be plated, and therefore to prevent injury when screwing it on, two ⅜in. holes should be drilled through the back, into which the pins of a pinhole spanner may enter.

To assemble the switch we shall require the finished handle-bar, and the first thing to do will be to drill a hole ⅜in. diameter through the back of the tee-joint in the centre of handle-bar. This hole must be bushed with vulcanised fibre or vulcanite, the bush to have a 3/16in. hole through it. Now take a length of insulated flexible twin-wire, such as is used for suspending incandescent lamps by, and pass one end through the hole in the bush just inserted, and carefully thread the wire along the inside of the

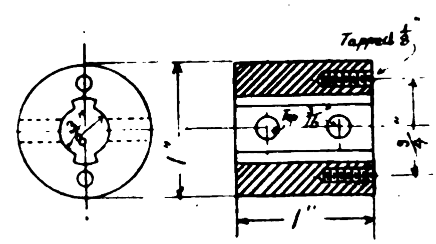

Fig. 91.

handle-bar, bringing it out at the left end. Untwist the end and twist each bunch of fine wires tightly together, so as to make it like a solid wire for about ¼in. back, the insulation being removed, of course. With a small

Fig. 92.

pair of pliers turn each end into a ring with an internal diameter of ⅛in. These ring ends are now to be soldered one to each of the contact-strips, which must be removed

from the insulating block (this latter being removed from the handle-bar) for this purpose. See to it that the soldering does not obstruct the hole through which the ⅛in. screw passes, and solder the wire ring concentric with the screw-hole. The contact-strips can now be replaced in the insulating block, the two screws put in, and the whole replaced inside the handle-bar and secured

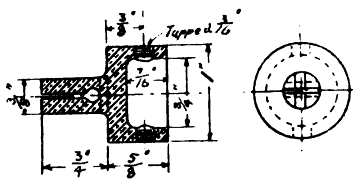

Fig. 93.

with four ³/₁₆in. countersunk set-screws. The face of the insulating block should be 3½in. from the end of the handle-bar. Any undue slack in the wire can be pulled back, but it should have a little, to avoid strain on the connections. Before fitting the block into place, note that the two ends of the wires where soldered to the contact-strips are not in contact anywhere. Now slip the handle, Fig. 90, on to the bar with the holes for screws above and below as seen in Fig. 89, which is a sectional *elevation*, not *plan*. Mark through these holes on to the handle-bar, and drill ⁵/₁₆in. holes to the marks. Push the contact-plug, Fig. 93, into the handle-bar till the tapped holes in the plug coincide with the holes in the bar. The switch is now in the "on" position, or should be if the insulating block has been correctly placed, and should be tested with a battery and galvanometer, or bell, to make sure. Remove the plug and elongate the holes so that the plug can be rotated by means of the screws I, Fig. 89, far enough to entirely break contact with the contact strips: the direction of rotation being in the contrary direction to the hands

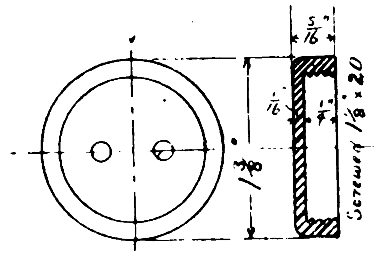

Fig. 94.

of a watch when holding the open end of handle-bar towards you. Having these slots cut, fit the two screws into the block through handle and bar, and let them fit tightly. Under the top one a flat steel spring about ¹/₃₂in. thick should be fitted, the part of the spring where it projects over the collar brazed to the handle-bar being ³/₁₆in. wide. File two shallow recesses in the collar, one for the "on," and one for the "off" position, bevelling the edges of recesses and under edges of spring to make disengagement easy. Stamp the words "on" and "off" in the recesses, screw the cap on the end of the handle-bar, and the switch is complete.

MILLWRIGHT'S WORK.—VI.

FIG. 30 illustrates wall-plates of cast iron, which are better than plates of wrought iron or steel, and neater in appearance. The bosses will measure from 2in. to 2½in. through, and the castings must make a fair bedding on the masonry.

When brackets for plummer-blocks have to be carried against the iron pillars of a shop, which is often a convenient arrangement, the brackets are either made to fit against facings cast to receive them, or they fit round an arc of the pillar. In the first case, studs or bolts are the means of attachment to the pillar. In the

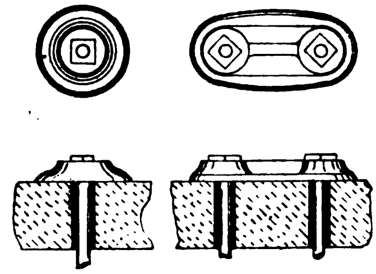

Fig. 30.

second, the bolts pass through caps behind, and the bracket is gripped by the friction of broad surfaces.

Fig. 31 shows a pillar bracket to carry a

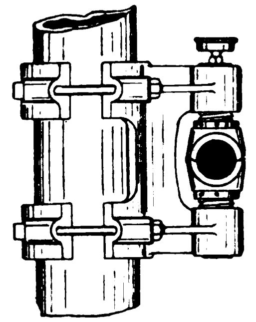

Fig. 31.

common block. Often, instead of separate clips A A, a single continuous clip is used, with set-screws in addition to the clamping bolts. This is heavier, but adds to the security of the fitting.

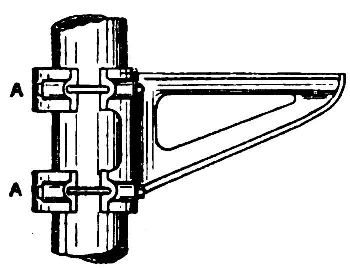

Fig. 32.

When swivel bearings are used, the outlines of the bracket are modified to suit. Then they are made either to be adjustable in the vertical direction only, Fig. 31, or in both directions, as in Fig 32. The latter of course have the advantage, because, though the bracket is fixed rigidly to the post, the swivel bearing can be moved up or down in its bracket, and the bracket can be slid laterally to and from the post, the bolts sliding in the grooves. These two designs are by the Unbreakable Pulley Co., of Manchester.

Hangers vary much in type. In the first

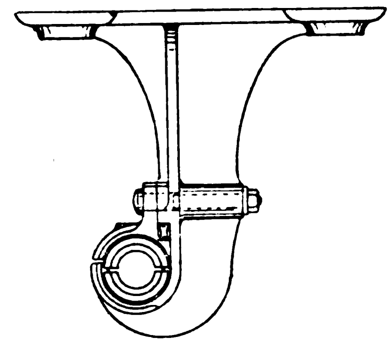

Fig. 34.

place, they are either single or double. One of the commonest of the latter is seen in Fig. 33. The idea in designing the double hanger is to avoid one-sideness in stress and strain. Except, however, for very heavy shafting, say over about

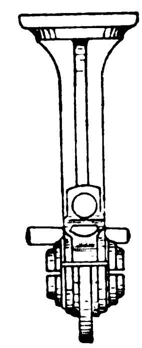

Fig. 35.

3in. in diameter, the single hanger is sufficiently good, when properly proportioned. The shaft also can more easily be put in place, because it need not be slid endwise.

The double hanger in Fig. 33 is shown with

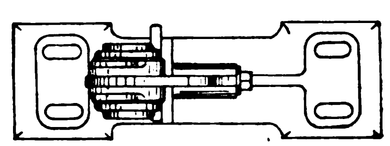

Fig. 36.

the brasses making a turned fit in their seatings. Angular brasses were formerly largely fitted, as in plummer-blocks. There is no power of adjustment in this bearing, excepting that in a lateral direction, by moving the hanger bodily by means

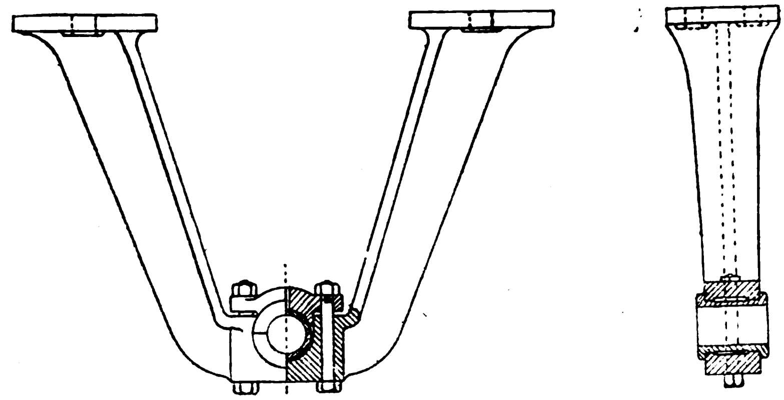

Fig. 33.

of its slotted bolt-holes. Many double hangers are cast with a bar connecting the feet, which lessens liability to fracture.

A form of hanger, of which, variously modified, the writer made a good many years ago, is shown

in Figs. 34-36 in elevation, side view, and inverted plan. The bottom brass fits into an angular seating in the main casting. The cap is secured with one bolt in a slot hole, to permit of vertical adjustment. To prevent the cap from slackening back, a wedge is inserted, as shown.

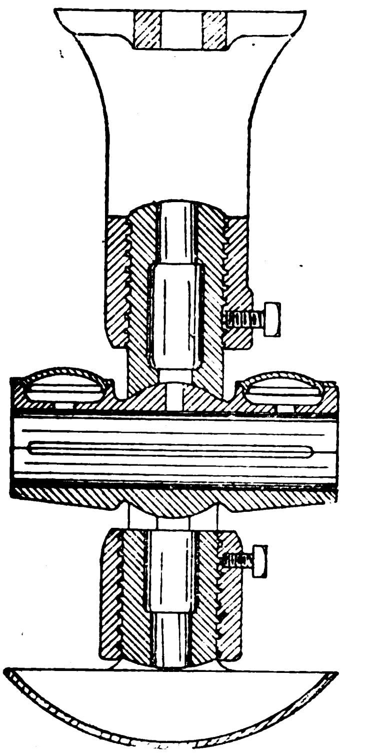

FIG. 37.

The hanger with adjustable bearings is now frequently used. In many cases it is a modified plummer-block, the foot of which is bolted to a face planed vertically in the hanger. In others, the stem, or stalk, of the hanger has a circular section upon which an extension sleeve of the bearing slides, and is pinched with set-screws. The conditions of fixing which exist in factories render many such variations in arrangement desirable.

The Sellers' hanger is shown in section in

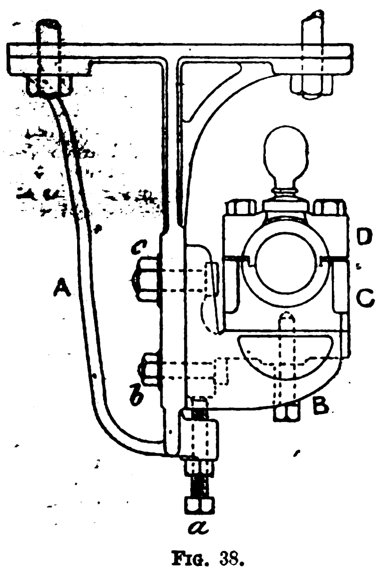

FIG. 38.

Fig. 37. It is seen to have the universal swivel movement of the Sellers' plummer-block, and the vertical adjustment also, by means of the screwed stems.

Figs. 38 and 39 illustrate a neat adjustable hanger made by Smith and Coventry. The hanger casting A has a flat vertical face, which receives a bracket B, which sustains the bearings C, D. B is adjustable vertically through slot-holes by the adjusting screw *a*. It is also capable of a pivoting movement about the bolt *b*, the bolt *c* moving in a slot-hole in B. The bottom bearing C fits B by means of a turned stud, and a screwed stud holds it down in place.

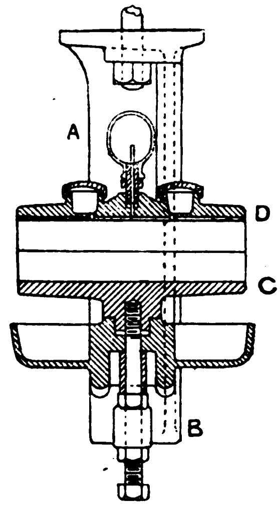

FIG. 39.

D is retained on C with set-screws. The lubrication is very similar to that already noticed in Article IV., a central needle, and side tallow cups.

Fig. 40 shows a hanger in which the bearing H is adjustable vertically through a sleeve sliding

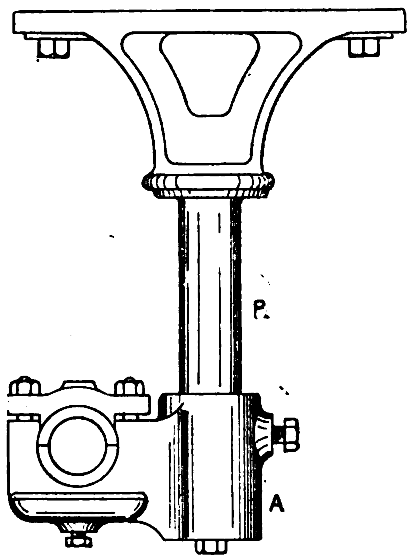

FIG. 40.

on a turned stem B. This also permits of swivel adjustment in a horizontal plane, and is suitable for the lighter shafting. J. H.

ORNAMENTAL TURNING.—XXVI.

By J. H. EVANS.

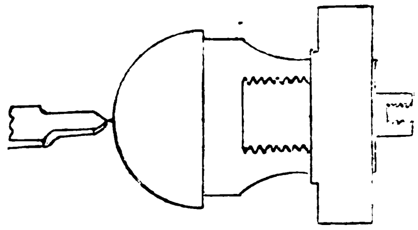
HAVING given the necessary details which will enable anyone at all proficient in the use of tools to make the additition of the dome or spherical chuck to his lathe, I now propose to continue the subject as suggested in my last, by showing as clearly as possible the most effective way of using it for the production of the many beautiful specimens of work of which it is capable.

A few simple diagrams will greatly facilitate our researches in this direction. We will take first the shaping and decorating of the simple hemisphere, and in doing this the first thing to do is to select the material, and, if for any specific object, decide the exact dimensions required for our purpose. This now is a matter of indifference, as we are simply defining the uses of the chuck, and the same movements apply equally for varying diameters.

The work must be chucked either in a metal chuck or a wood plug firmly driven into one, and as the range of adjustment in the slide of the chuck is necessarily somewhat limited, the chuck should be kept as short as possible. The work must then be reduced by hand-turning approximately to the desired shape—viz., a hemisphere. Of course, the more correctly the same is formed the less irregularities there will be to remove when on the dome chuck. Before the work is transferred to the chuck, the transfer must be placed thereon in order to insure the axial truth. Another point to study is this: be sure that the chuck which holds the work is less in diameter than the material to be operated upon, as it then admits of the cutter passing out at the extreme diameter if it is required so to do, which, in many cases it is.

The adjustment of the chuck for this, I may say, primary example, is a simple matter, and is as follows:—By reference to the diagrams Figs. 1 and 2, the settings will be clearly demonstrated. When the work is reduced to the desired form, a minute test-point should be left at the centre for the purpose of future adjustment; as to axial truth, there are two ways of adjusting the centre, as shown by Figs. 1 and 2. Having

FIG. 1.



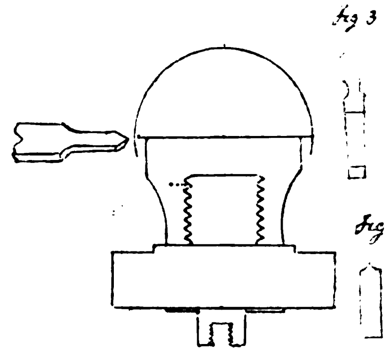


FIG. 2.

placed the work on the dome chuck, the latter is adjusted to the vertical position, as seen in Fig. 7 in my last. The slide-rest is set parallel with the lathe-bed, and a double-angle tool placed in it. This is moved laterally until in perfect agreement with the test centre, and to more conveniently ascertain this to be perfectly correct, the chuck is moved to the horizontal position, which will bring the test-point towards the operator, as seen in Fig. 1. The nut at the back of the right angle arm is now released, and the slide of the chuck moved out to the position. That will allow the tool to trace over the hemisphere, after which the nut is again tightened. If the plane form is accurately turned, the drill or fly-cutter may take the place of the fixed tool. If, however, any appreciable error exists, it is easily discovered, and that portion that is in excess of the other part may be removed by replacing the work on the mandrel nose and re-turning it, until by trial it is found sufficiently near.

The precise hemisphere, however, may be obtained in another way if thought desirable. The drill-spindle is placed in the slide-rest, having a broad square-end drill, and by taking a light cut, just enough to remove all superfluous material, to effect this the chuck is partially rotated under the influence of the left hand, arrested by the segment stops, and when the first cut is decided as to depth, the worm-wheel is moved two or three divisions only, and by repeating this process throughout the whole diameter of the wheel, the hemisphere is brought to the correct shape. This, I am bound to confess, is a very long and tedious job, and as it is not really necessary, I do not advise its adoption; at the same time, I explain it as it forms one of the movements which may be required.

We will now assume that the plain form of the hemisphere has been so far produced, and that it is desired to decorate it with a series of reeds;

there are two ways, again, of producing these. The drill-spindle carrying a quarter-hollow drill, Fig. 3, is perhaps the most suitable, for reasons that will explain themselves hereafter. The fly-cutter is always preferable, and whenever it can be employed without the framework interfering with the passage of the cutter through the work, I strongly recommend its use in preference to the drill. For our present purpose, if the vertical or universal cutter is used, a double quarter-hollow, Fig. 4, will be that which is most suitable for the purpose.

Having decided by the two proverbial trial cuts the amount of penetration required in accordance with the partial rotation of the worm-wheel, it only remains to continue the same movements throughout the entire diameter of the same, to complete the pattern. It is, I hope, needless for me to say that the number of divisions taken must divide equally into the 96. The result of these proceedings is shown by Fig. 4, which will be the same, whether the drill, Fig. 3, or the cutter, Fig. 4, is used; but, as I have already mentioned, the fly-cutter is always the most satisfactory.

The result, as seen in Fig. 5, is a very effective one, but the decoration of the dome is not by any means confined to this particular form—a round nose, or a step-drill, also a figured moulding tool may, of course, take the place of that we have just considered, and as it is only the difference in the precise shape of the tool, I need not say more on this point, except that, by leaving an interval of polished space between the successive reeds, is most effective; also these may be pierced

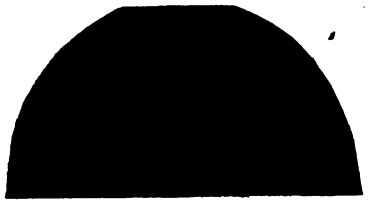

Fig. 5.

seriatim with a series of round-nosed tools varying in size, or cutting pearls after the same manner, but with a suitable bead-drill.

It may happen that when setting-out the divisions of the worm-wheel, the cut will be brought so close together at the top of the dome as to almost become obliterated, while at the diametrical line it will be all that is desired. This, to a considerable extent, may be avoided by slightly lowering the slide of the dome chuck, thus causing the depth of the cut to be correspondingly reduced at that part of the dome. This alteration, if considered necessary, would, of course, be carried out when deciding the penetration of the trial cuts.

By reference to Fig. 2 we see that the work represents more than the hemisphere. This is arranged in accordance with the desire of the operator, and it will be at once obvious that the increased proportion of the curve is accomplished by the further rotation of the mandrel between the segment stops.

We have now considered the decoration of the hemisphere sufficiently to clearly demonstrate the manipulation of the chuck for this particular purpose. Such subjects as may require a dome at the summit, but not of the pure hemispherical character—that is, a flatter curve may better answer the purpose—this, like that we have now studied, is first roughly shaped by hand to the desired curve, then placed on the dome-chuck, and the slide lowered until the point of the fixed tool traces as nearly over it as it can be made to do. By these adjustments a large variety of curves are available. Cylinders with circular tops are of much source for many decorative objects. This will be fully shown as we approach the illustration of finished specimens.

We come now to the production of the combined curves—by this I mean that the concave curve may be made to join the convex with equal precision, and a large number of solid forms of this character may be rendered very beautiful indeed. By reference to Fig. 6, this will be seen as placed on the dome-chuck, having been first shaped by hand. The chuck is then adjusted to follow the dome or convex curve, the centre of the tool being precisely coincident with the dotted line A. The fixed tool is then removed, and the Universal cutter substituted, adjusted to cut vertically, and the cutter selected suitable for the type of decoration desired. The cutter is set out to the necessary radius—as an example, the engraving, Fig. 6—the two curves are both of 1in. radii, therefore the tool must be set out to this extent; the cut is then set in by means of the depth-screw. I may here point out that the steel

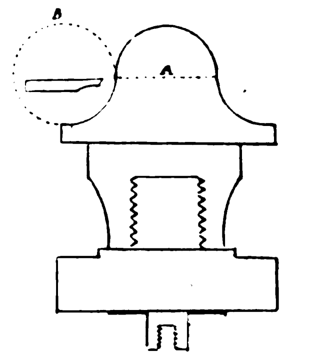

Fig. 6.

bridle, to place the top slide of slide-rest under control without the use of the lever, should in all cases be employed, more particularly with this chuck, as it will be recognised that both hands are already usefully employed. Having set the penetrations to the required depth, decided by the stop-screw, the concave curve will be thus cut. The cutter is still revolved at a high speed; but, until the chuck is moved, it passes out through the course of the dotted line B; but, on the chuck being rotated through the allotted space, the cut is passed over the dome or convex curve. This done, the chuck is returned to the vertical position, the cutter withdrawn, and the worm-wheel moved to the division that has been decided upon, and these movements being performed in unison through the whole diameter, the pattern will be completed. This particular example does not afford the opportunity for any display of elegance, but like those preceding it, is simply a rudimentary specimen, illustrative of the manner in which the combined curves are obtained.

There is a large field for the display of elegant taste in the designing of tazzas, vases, &c., composed of this class of work. The different ways in which such can be decorated is practically endless, and will afford a most interesting subject to study.

I have, I think, now given a fairly clear insight into the working of this chuck, for what

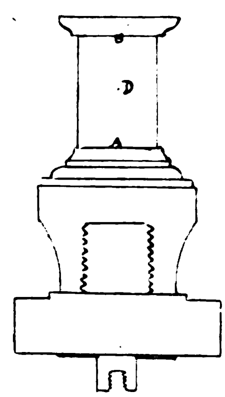

Fig. 7.

may be justly termed its legitimate purposes—viz., the cutting and ornamenting various curves, convex and concave. But it has still another, and I may say entirely independent, use; and this is the formation and ornamentation of polygonal solid forms, which may contain any number of sides or facets; these may be, as stated, contained in one solid form, or built up in several pieces, in which, of course, the same section is maintained throughout. Such work is found of great service for the decoration of caskets, boxes, and also pillars that may require a base and capital composed of like features. These are all obtained with equal facility as the foregoing examples already considered. The proceedings are as follows:—

The dome-chuck is again set accurately to the vertical position and tested by the set-square. In this position it remains securely held by the segment apparatus. The work is first shaped by hand approximately. In the circular form the dimensions must be considered with regard to the various diameters, as applying to the measurement across the corners when the polygon form is finished. When thus prepared it is mounted on the dome-chuck while in the before-mentioned vertical position, and if from any cause there is little or nothing in the shape of material to spare, the transfer chuck must intervene; if, however, there is sufficient space, this may be dispensed with, as the limited traverse of the slide of the chuck may be found inconvenient in the case of works of large dimensions.

The slide-rest is now set transversely, or at right angles to the lathe-bed, and the eccentric cutter takes the place of the fixed tool previously used to adjust the rest to the correct height of centre. A round-nose tool is employed to shape up the sides of the square, or whatever shape is decided upon. By reference to Fig. 7 we see an outline of a short pedestal as mounted on the chuck ready for process; the eccentric cutter is set out so that it will describe a circle covering the size of that part between the base and capital A to B, the work being adjusted by the slide of the chuck so that the centre D corresponds with the axis of the lathe mandrel. The cutter is now revolved at a high speed and passed over the part to be cut by the main screw of the slide-rest, and it is necessary to first cut somewhat nearly to the required depth, and then turn the worm-wheel round one-fourth, or 24 divisions, when the

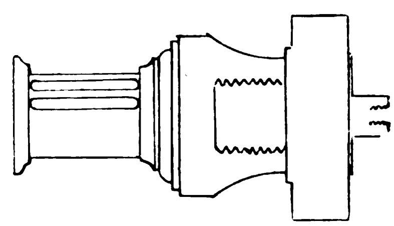

Fig. 8.

tangent frame is fitted as I recommend, to move in and out of gear, this is a very simple matter, and does not necessitate the repeated movement of the chuck from the vertical position, in order that the winch handle may be made to operate for the purpose of taking 24 monotonous turns of the same.

Having cut two sides, it will be easily seen if the depth is sufficient to bring up the corners, and until all four are cut a slight amount should be left, and the final adjustment as to depth made for the terminal cut. If the height of the pedestal be greater than can be covered in one cut, in consequence of the limited extension to be obtained in the slide of the eccentric cutter, the work must be raised or lowered by the main screw of the chuck, and the same process repeated. When the body is thus cut to the desired size the base and cornice may be shaped to the form of a square in the first instance, and afterwards shaped by moulding tools with the entire figure contained in one tool or by separate tools revolving in the universal cutter, set to operate horizontally, or by moulding drills in the drilling instrument. If the latter is employed, the work must be brought to closer contact for the succeeding cuts to complete the figure by again raising or lowering the arm of the chuck; but when the eccentric cutter is used this may be avoided by increased radius being given to the tool. When the base and capital are alike, both can be cut at one cut.

Referring to Fig. 8, we see that the same can be treated in still another way, and this is by a series of flutes or other decoration being continued along each facet. The dome-chuck is now turned to the horizontal position, which brings the work to the position seen, the centre being still, of course, maintained, the chuck arriving in this position by simple partial rotation. The example is illustrative of the power of fluting the flat sides of the square, and to effect this the work is raised or lowered by the slide of the chuck to the desired position to suit the number of flutes required, the traverse of the drill being arrested by the fluting-stops in the usual way.

I will now conclude what I may term the primary or rudimentary manipulation of this important instrument, and will introduce in my

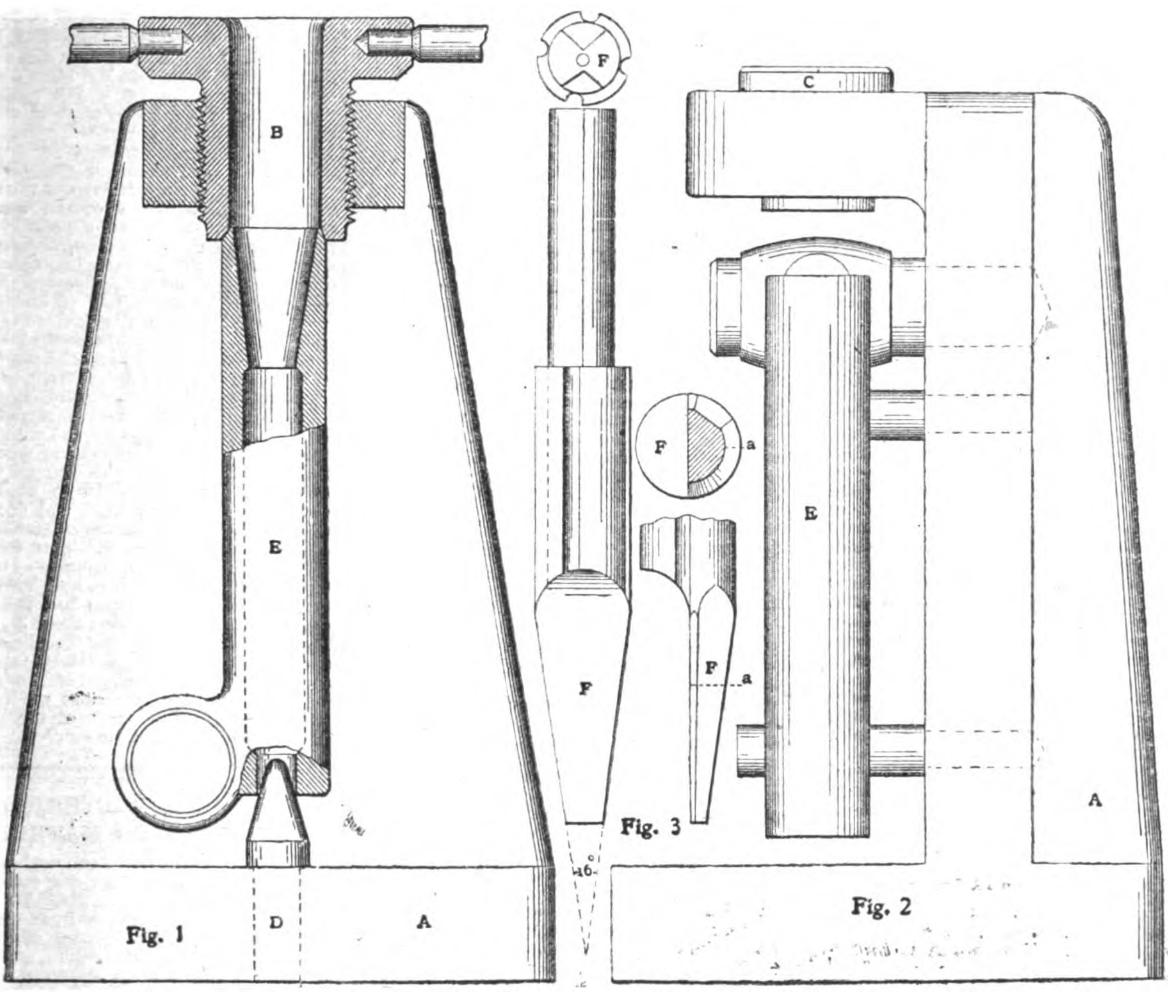

Fig. 1 Fig. 3 Fig. 2

next a few examples of more finished work, which may be regarded as an extension of what I have already described, and will, I trust, lead up to still more extensive and interesting productions.

A BICYCLE JIG.*

THE accompanying cuts illustrate another style of jig used frequently at the Peoria Rubber Company's works. Two views of the same style of jig serve to show different methods of holding work, and another cut gives an idea of a reamer for making the taper-hole for the seat post and handle-bar stand cones.

The machine business (generally prolific of conventional terms) gives the name of spider jig, I believe, to such a one as is seen in Fig. 1, owing to the appearance of the clamp-bushing combine at the top, with its four spreading arms or long handles. This bushing B clamps centrally the piece E and guides the reamer F, Fig. 3.

For opening the hole resting on the stud D, Fig. 1, the piece is held in a reverse position, as seen in Fig. 2, the offset hole in E resting on a heavy stud, with a smaller one for a back stop and another for a side stop. No clamping is done in this work, except to secure the jig to the drill-press table.

The reamer F is milled half-way off and bevelled, as shown, to cut, being 16° taper in this case, and well provided with flutes for the lubricator to run down, the latter being pumped on to the tool continuously. The material worked on is malleable iron, and the reamer illustrated here gives the best of satisfaction.

GERMAN WORKSHOPS.

WE extract the following from an extremely able and interesting report in this month's *Amalgamated Engineers' Monthly Journal*, a trade-union organ, which, as now conducted, reflects the highest credit on the splendid society that owns it, and on its able executive:—There are one or two general features common to German workshops. In the first place, the fencing of machinery, the general protection of workmen and provision for their comfort is much more complete than in this country, and the shops are more spacious and cleanly. This may be, to some extent, due to the stringent governmental inspection, brought about contemporaneously with, if not as the result of, accident and other insurance laws; but I am inclined to think that much of it is due to voluntary initiative on the part of employers. I saw many things which went much beyond the law's requirements, and which are altogether unequalled in this country.

Another common feature is the modern appearance of most workshops and the use of first-class appliances. Everywhere new factories are building, and most of the shops that I visited were extending. Machinery was everywhere being put down, and a great deal of that at work is dated this year or last.

And a no less marked feature common to German workshop life is the leisurely manner in which the men go about their work. Although piecework is common, I saw nowhere any bustle. With one exception, in all the shops visited, men smoked during working hours, and in most of them there were canteens or other provision for getting refreshments while at work.

Hours of Labour and Wages,

of course, compare unfavourably with those current in this country, although there is certainly not the marked difference which is here generally supposed. And when due allowance is made for the stopping time for refreshments, it is doubtful if the actual working time much exceeds that in the area covered in this country by the Employers' Federation. At Düsseldorf, the outside or inclusive hours are 60 per week, with one main break in the day—namely, from 12 to 1.30. In Augsburg the hours are the same as at Düsseldorf. But there are two recognised breaks for refreshments in the forenoon and afternoon, of a quarter of an hour each, which takes three hours per week from the inclusive time. At Chemnitz the hours are about the same, but vary a little from shop to shop. At the main place visited there is an elaborate coffee boiling arrangement in the middle of the shop to which the men can go three times per day and get coffee at 3 pfennig (1¼ farthings) per cup. In this shop the hours are from 7 to 12, and from 1.15 to 6.15, except one day in the week, when work ceases at 5. The inclusive hours are, therefore, 58¾ per week. At another, however, which was visited, the hours were 61 per week. At Berlin the working day is shorter than elsewhere; but, curiously enough, and very confusing to me in making inquiries, it varies considerably, in some cases being different in length in different departments of the same firm. The maximum inclusive time is, however, 59 hours per week, and the minimum 54, made up as follows:—6 to 12 and 2 to 6, except on Saturdays, when work stops at 5, = 59; from 7 to 12 and 1.30 to 5.30, = 54. But in each case deduction has to be made for refreshment stoppages, amounting to half an hour daily. And it may here be said that the shortest working day obtains in the largest, best equipped, most scientifically organised, and best paying concerns that I saw, those of the Allgemeine Electricitäts-Gesellschaft, which employ some 14,000 people, and Messrs. Siemans and Halske's, employing nearly as many.

The Wages Vary

more than the hours, not so much, however, as between town and town as between man and man. There is no standard or minimum wage rate inforced by the unions in the engineering trade upon their members, or, for the matter of that, the unions in any other trade except the printing. In most of the shops that I visited piecework was more or less general; one firm, however—that of Reinecker, of Chemnitz—absolutely bars it, every man being on day work. In the first shop visited at Düsseldorf the manager told me that the wages of the 1,200 people employed averaged over 4s. per day. This included boys and labourers. Most of the fitters and turners were on piecework. There was no sub-contracting, each man being paid through the office, and skilled men earning about 6s. a day as a rule; young men less. The smiths, however, earn more, the earnings of the leading heavy workman averaging 12s. to 13s. per day. The apprentices, who work altogether, get 9d. per day for the first year, and serve three years. I found that these conditions were those generally obtaining in Düsseldorf, excepting in regard to apprentices, who serve, as a rule, four years, starting at 6d. and advancing to 1s. 6d. per day, but earning by piecework an additional 30 to 40 per cent. on their day-work rate. Attendance at technical schools twice during the week is made a condition of employment on the lads in Düsseldorf, and is encouraged in the case of young men. In some cases wages are paid only once a fortnight. The wages of labourers are 3s. per day, those of moulders 7s. per day and over.

At Augsburg the wages are a little lower than at Düsseldorf, living also being a little cheaper. I was told, however, by Mr. Krantz, manager of the Maschinenfabrik Augsburg (of whom more anon) that no skilled mechanic there earned less than 5s. per day, and many of them earned more.

At Chemnitz the rate, or average earning, is perhaps a little lower than at Augsburg, and the general standard of life appeared to be lower than any other place visited. There is little regard here for women, who are seen carrying the hod, sweeping the streets, and even using the pickaxe, being paid

* By A. H. Cleaves, in the *American Machinist*.

from 1s. 9d. to 2s. 6d. per day. The average earnings of the engineers are about 5s. per day, exceptionally skilled men earning more.

At Berlin the earnings are distinctly higher, many of the men at Siemens and Halske's earning nearly a shilling per hour. It was somewhat difficult to get a knowledge of the rate for engineers throughout the district, but in the shops visited, which between them cover nearly 30,000 work-people, the earnings are about 38s. per week per man. I was told, however, at Berlin and elsewhere that the present level of wages is higher than ever before, and that this was due to the high tide in industry of the last few years.

In Regard to Holidays,

they are much the same as in this country, except that the minimum number is fixed by law. No work is allowed in any factory, or workshop, or place of business—excepting restaurants and certain other places scheduled in the Act—on eight days in the year. These are: Christmas, two days; Whitsun, two days; Easter and Good Friday, two days; Ascension Festival, one day; and Repentance, one day. Sunday labour is also forbidden, excepting under "urgency and emergency," even shops—except restaurants—being compelled to close at two o'clock. Concerts, theatres, &c., are open on Sundays, which is the principal day for entertaining enterprises. In addition to the above, there are holidays peculiar to districts. In the Lower Rhine district, for instance, the three days immediately preceding Ash Wednesday are generally observed as holidays, it being a time of carnival, to which the nearest approach in this country is the "wakes" week in the Lancashire towns. In Düsseldorf and most of the other towns on the Rhine there are two more holidays in July, when the Old Shooters' Guilds hold their annual festivals. These are called "Kirmes" (Kermess).

My observations covered three places in Düsseldorf, those of Messrs. Haniel and Lueg, the Hohenzollern Actiengesellschaft, and Ernest Schiess, which were visited in the order named. The first two are pleasantly situated in the outskirts of the town.

Messrs. Haniel and Lueg

are manufacturers of centrifugal pumps, mining plant, and hydraulic machinery. A speciality of their business is pipe-moulding, which is done by special machinery, invented by themselves, and over 2,000ft. per day are turned out. The railway runs right into the yard, which is roomy and set out by flower-beds, flanked by bicycle exercise space, having a lean-to at one end for the housing of the machines. Close by are shower-baths for the use of the men, and well-appointed dining-room and first-aid arrangements. The engines and much of the machinery were made by the firm. The woodworking machinery is from Leipzig, most of the lathes and planing machines from Schiess and another firm in Chemnitz; but there are a few of Whitworth's, and one of Davy's of Sheffield. There are some beautiful lathes in the turnery, one or two of them having three and four rests, but by no means worked to full capacity, which also applies to most of the machines. I noticed one or two cases of two machines being worked by one man. I also saw here a beautiful little machine (American) for slotting key-ways, being about 3ft. in height, the cutters being drawn down by gear in the base, the top being a turned surface about a foot diameter, to which a wheel, weighing perhaps half a ton, was attached in the course of a few minutes while I stood by. There are overhead cranes, and the works generally are well equipped and full of work, having some very heavy work on hand at present, some of the turned parts for mine drawing gear being over 20ft. in diameter, and being turned in horizontal plate lathes. The manager, Mr. Riemer, very kindly conducted me round, and was most willing to give all information. He had spent some time in England many years ago, and knew English conditions fairly well. He had been successful in obtaining hydraulic work for, I think, Italy, for which Messrs. Armstrong had tendered. The firm, he said, was doing well, and he looked forward to increased prosperity.

The second shop is not so large nor so well found as Haniel and Lueg's. It is being extended, however, on improved plans. The speciality is a locomotive without a firebox, it being charged with steam to run, if my memory serves me right, about 20 miles. The woodworking machinery here is from Robinson's, of Rochdale, and there are many lathes and other machines from Hulse's, Craven's, and Smith and Coventry's. Most of the new machines, however, are of German make, coming either from Chemnitz, Düsseldorf, or Hanover. Here, again, the men appeared to be working very comfortably and leisurely, and the boys had decorated the machines with green boughs and flowers, it being the day before Whit Sunday.

The third is the tool-shop of

Mr. Ernst Schiess.

In some respects this shop is even better than the first one visited, though more cramped, being in the centre of the town. It is, however, very lofty, and well equipped with electrically driven travellers and other modern appliances. The men are not catered for as at Haniel and Lueg's, although there are washing conveniences here as elsewhere. They make very heavy machine tools, and the work is really very good, although, judging from my observations, the firm is likely to find a difficulty in the world's market as far as price is concerned. All the machines in the shop are of their own make, excepting two or three of Brown and Sharpe's milling machines, and a very large planing machine also from America. The lifting tackle is very good, and made by a firm—Maschinenbau-Actiengesellschaft, formerly Bechem and Keetman—which I understand is a sort of German Tangye, in Duisburger. The men appeared to work just as comfortably as in the others, although I noticed one or two cases of men working more than one tool. I had a long talk with the managing director, a very genial man who spoke English, and who knew all about English makers, and spoke highly of Messrs. Craven's and Smith and Coventry's tools. None of his tools, he said, were yet in this country, or in America, although they had had inquiry recently from Carnegie's people, of Pittsburg.

The next shop visited was that of

The "Maschinenfabrik Augsburg,"

over which I was conducted by Mr. Krantz, the managing director, on the afternoon of the opening day of the Augsburg Conference. There are from 3,000 to 4,000 people employed here, the staple work being printing machines. The firm is the oldest printing machine makers in Germany (perhaps in the world), and have shops even larger than those at Augsburg situate at Nürnberg. Mr. Krantz proved to be quite an interesting personality, and a few lines may be appropriately devoted to him. A thick-set man of 50 or 55, with iron-grey beard, black shock head of hair, and boisterous manner, he put me in mind of Mr. Wm. Allan, of Sunderland. He wears loose trousers, a jacket of material something like felt, a peaked cap with flat top, and an immense leather strap round his right wrist. This latter may be a relic of other times, he having been an army officer and a huntsman, to which he was still partial, but for which, he said, he had now no time. He was most effusive in his welcome, and took me everywhere, being heartily in favour, he said, of all that I had advocated the night before, and of workmen's rights generally. Eight hours were, he thought, long enough for men to work, and he had been much interested in our struggle of two years ago, asking me for printed matter and full particulars, a request with which I afterwards complied. Altogether I found him a very fine type of man, combining a large flow of the milk of human kindness with, at the same time, disciplinary power. Smoking at work was here barred, and refreshments had been systematised. Prior to stopping times for refreshments, labourers went round to ascertain the men's wants, and then brought them beer, coffee, bread, sausages, &c., from a canteen. This latter place was visited, and we had beer, bread and sausage together. It was amusing to see, as we trotted about, the exchange of salutes between him and the men, most of whom touched their caps as he approached. He did not want it, he said, and, moreover, its discontinuance would be a saving on both sides, for he would not then have to salute them. But bowing and saluting in the district seems to be general, soldiers and priests coming in for special attention. The same day I had seen a little chap of about 10, meeting an old lady, put his little body at an angle of 30 with his legs.

As may be imagined, Mr. Krantz has very fine and large ideas as to

What an Engineers' Shop Ought to be,

and, as far as he can, he is getting these ideas put into concrete form. Some parts of the works are quite new, having been built right over the old parts before the latter were removed. But he is far from satisfied, and foundations are being got out for extensions which are, he said, to put everything there as yet into the shade. At present the works and yard cover an area of 600 yards by about 300 yards. The railway runs down the centre of the yard, the main shops being parallel with it, and skirted on the other side by a canal. Along the side of the shops there are wooden posts at intervals of about 15ft., with little wooden boxes on top, with holes for birds to enter and build their nests. Provision is made for the shops being all heated by piping, and, where there are two floors, there are interruptions in the ceilings for air outlet and lighting. There are also electric cranes, in some cases running one over the other, and the main turnery is 180 mètres (600ft.) long. Special shops are reserved for apprentices (who don't work piecework like the men), who are separated into gangs, each in charge of a man, for the first three years. After that, in the fourth and last year, the boys are placed with the men. All the shops are designed on strictly geometrical lines, the windows and bays being of a certain measurement, and the spans being multiplies of the same. The machine tools are good and also the work turned out. The tools are mostly of German make, some from Chemnitz, and some from Düsseldorf, but there is a little from America and from this country. The shop is full of work, and Mr. Krantz looks forward to continued prosperity, and is preparing for it. Some beautiful specimens of their work are being prepared for the Paris Exhibition.

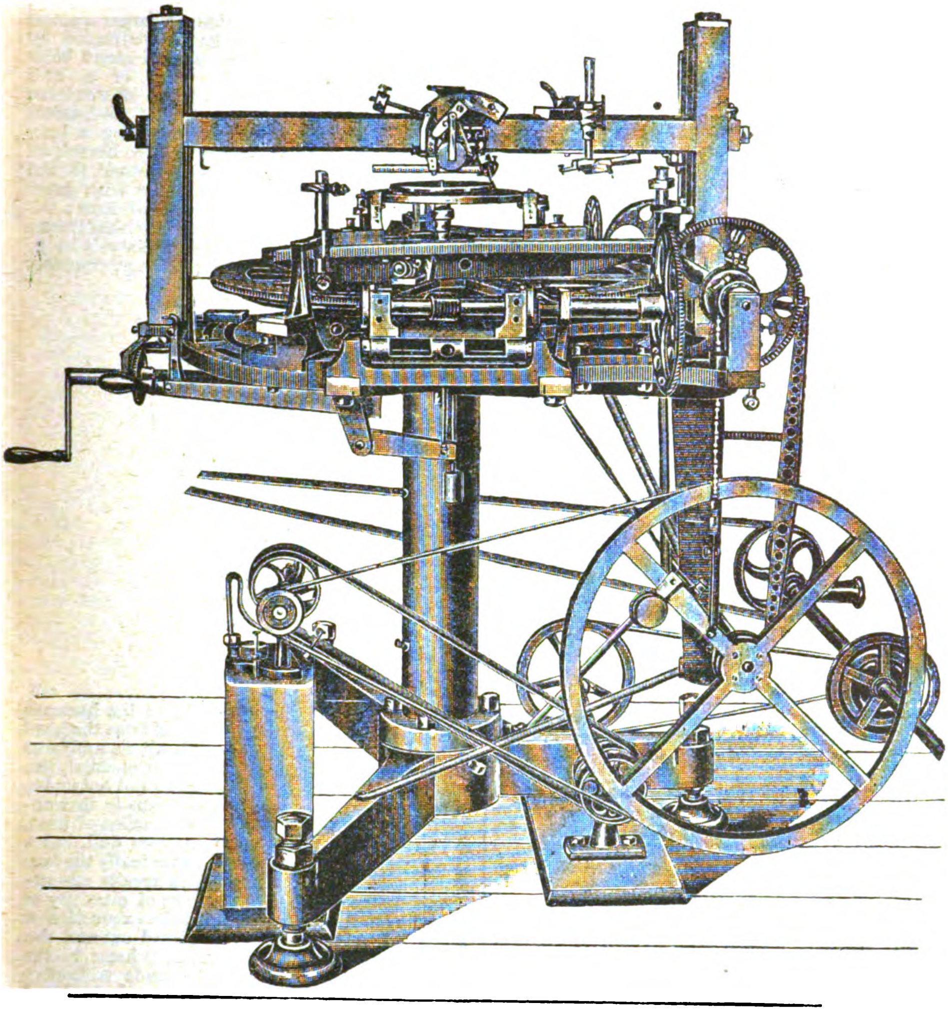
The adjuncts are arranged on a most generous scale. Five doctors attend the works daily (in addition to an eye specialist) and the men have the choice of the five. Of course, much of this is required under the Act, but the provision made goes much beyond the Act's requirements, and it had been so before the Act came into operation. I saw one of the forms which the governmental authorities required, giving particulars of accidents. It was brought for Mr. Krantz's signature as we sat in the canteen, and the particulars required were in respect to an accident that had happened three days before, when a man had had his thumb slightly injured. It required the man's name, occupation, wage, whether married or single, how long employed in the place, how the accident happened, the witnesses of it, if it necessitated the man ceasing work, and other details. After leaving the canteen we went into the baths, which are open to workpeople after working hours at any time, and during working hours to the boys or anyone on making application on the score of ill health. They include a small swimming-bath, as well as numerous shower-baths. Adjacent to the works there are blocks of dwellings for the workpeople who care to live in them, and I was told that the rents were about 3s. 6d. per week for three rooms. Altogether the whole place is conceived on a grand scale, and its manager brought to my mind Carlyle's figure of the "Captain of Industry." If the extensions are to be so much better, then, in the words of the poet of John Gilpin, "may I be there to see."

COAL AS A BACTERIOLOGICAL FILTERING MATERIAL.

MANY materials have been used as media in the filtration of sewage, and among these coal has given very good results. At the Wolverhampton sewage works there is, as we learn from a paper read before the Institute of Sanitary Engineers, by Mr. Ernest Berrington, a coal filter, 40ft. 6in. long by 20ft. wide by 5ft. deep, with an area of 90sq.yds., which is doing excellent work. It is constructed as follows:—A layer of 6in. of coal about ¾in. cubes in size is laid over the drain pipes. Above this comes a 3in. layer of ½in. cubes, and above this 3ft. 9in. of ⅜in. cubes. The top layer consists of 6in. of fine coal-dust. The sewage is applied by means of perforated pipes laid on the surface, and is allowed to percolate through the filter continuously. At the present time this filter is allowed to work for twelve hours, and is then allowed to aërate for a similar period. The rate of filtration is about 200gal. per square yard, equal to one million gallons per acre per day. The sewage is first precipitated in tanks, and the tank effluent passed through the filter. The analyses show the purification on organic ammonia effected by the tanks on the raw sewage to be 85 per cent., and 98·2 per cent. by the tanks and filter combined. On the "oxygen absorbed" test the purification of the tank effluent is 91 per cent., and on the "organic ammonia" the purification of the filter on the tank effluent is 88 per cent. These results show that coal makes a very effectual filtering effluent.—*Engineering.*

FLASHLIGHT PHOTOGRAPHY ON THE CHEAP.

I HAVE seen a great many hints on the taking of flashlight photographs, but very few on the way to make the necessary apparatus at a smal cost, so I hope this will prove useful to some. Firstly, get an ordinary clay pipe (½d. each) and a small piece of board about 9in. long by 2½in. to 3in. wide. Near one end of this make a hollow to roughly fit the bowl of the pipe, and from this a groove to take the pipe-stem; then, just on each side of this groove, bore two holes about 3in. apart, and by means of these tie the pipe firmly down with string. Next get some copper wire (1d. worth) and form it into a ring about 2½in. in diameter, and fix it about ¾in. above the pipe-bowl by twisting the remainder of the wire round the bowl of the pipe; then get an empty pound tobacco or soft-soap tin, and cut it in two from the top to the bottom, and nail it to the board about 2½in. behind the pipe-bowl, so as to form a reflector; then get a foot of india-rubber tubing (cost about 3d.), and fix this on to the end of the pipe-stem. This will complete a useful flash-lamp at the modest price of about 6d. For the screen get the lid of the largest cardboard box obtainable (for instance, a lady's dress box) and cut out the middle, leaving a margin of about 2in. all round, and gum a sheet of tissue-paper tightly over the opening; then make a hole in both top



corners, through each of which fasten a long piece of string. I will now explain how to use these. Take the screen and hang it from a picture or gas-bracket, or anything handy, so that it will come between the flashlight and the object to be photographed; then get the flash-lamp and wind some cotton-wool round the wire ring above the pipe-bowl and soak it in methylated spirits, and put the magnesium powder in the bowl of the pipe. When you have the sitter in the right position uncap the lens, light the cotton-wool, and give a sharp blow through the indiarubber tube, and "the deed is done."—A. M. B., in the *Photographic News.*

WURDEMANN'S DIVIDING ENGINE.*

SOME years ago Mr. William Wurdemann, of Washington, D.C., devised a novel dividing-engine now in the possession of Berger and Sons, of Boston, on which very accurate work has been done in graduating circles for astronomical instruments. As no account of this engine has ever been published, and but few persons are acquainted with its construction, a short description of it may be interesting to many readers of your valuable paper.

Engines of this kind as made by Troughton, of London, and others, consist principally of a circle or wheel supported upon a perpendicular axis and moved by a tangent screw gearing with teeth corresponding to the section of an internal screw cut in the edge of the circle. There are 2,160 of these teeth, so that one turn of the tangent screw moves the circle exactly ten minutes of arc. The circle to be graduated is secured upon the circle of the machine, and the cutting diamond or graver is moved in a radial line by means of a swinging frame attached to the framework of the machine.

The improvements invented by Mr. Wurdemann and embodied in his engine are many and of great importance, securing greater accuracy in results and requiring less attention from the operator, it being automatic in action and driven by a small motor.

The improved machine is shown in the engraving; in it two driving screws are employed, geared together so as to move in the same direction and at the same speed, and arranged on opposite sides of the circle. Driving the circle by two screws tends to divide and equalise any errors or differences arising from slight imperfections in the gear teeth or screws, and any wear of the parts has a tendency to eliminate the errors. Furthermore, in consequence of the greater contact surface between the moving screws and the engaging teeth of the circle, there is less pressure and friction on these parts and the bearing is relieved of side pressure.

The moving screw has a drum-head graduated to 120, so that the automatic movement may be arranged to five seconds of arc. There is also a second drum-head with 200 graduations arranged for dividing the circle according to the centesimal system.

The axis of the circle is of novel shape, it being a perfect cylinder where attached to the circle and ending below in a hard steel cone that bears the weight. The effect of this long cylindrical axis is that the circle turns with uniform ease under all conditions of temperature. The axis enters a cast-iron column, into which its upper end is perfectly fitted, so as to turn easily without any possible shake. The column is supported on a cast-iron tripod with three levelling screws that step into iron cups. On the upper part of the column is fixed a cast-iron frame, on which all the necessary moving parts are supported. The circle and its bearing are of hard cast iron; it will be seen that all the parts are made of a dense hard metal, having a small coefficient of expansion, consequently the working of the machine is not affected by slight changes in temperature.

The bars that carry the tracing works are placed on one side of the circle, so that these works stand out free and accessible in all their parts, while the tracing point is carried directly over the centre line of the circle, and is not interfered with in any adjustment that may be necessary during any one operation.

Although the circle of the engine is but 30in. in diameter, a meridian instrument circle of 45in. diameter has been graduated upon it to two-minute spaces, making 10,800 lines with a very satisfactory result, the probable error not reaching two seconds of arc, a degree of accuracy never before attained.

* By Capt. H. P. Sanders, in *Scientific American.*

UNUSUAL FOOD.

LION flesh is said to be very good eating, but tiger is tough and sinewy. Nevertheless, the latter is eaten in India, as there is a superstition that it imparts strength and cunning to the eater. Bear's flesh is a great favourite in Germany, and smoked tongues and hams are considered great delicacies. On account of the rarity of Bruin, they are expensive. Sausage—so dear to the Teutonic heart and stomach—is also made from bear liver; 25lb. of sausage can be made from a single liver.

There appears to be considerable diversity of opinion as to the merits of elephant's flesh. In India and Africa it is a favourite dish with the natives; but a European who has travelled much in Africa says: "I have tasted elephant over and over again. It is more like soft leather and glue than anything I can compare it to." Another traveller, however, declares that he cannot imagine how an animal so coarse and heavy can produce such delicate and tender flesh. All authorities, however, agree in commending elephant's foot. Even the traveller quoted above who compared elephant's flesh to leather and glue, admits that "baked elephant's foot is a dish fit for a king." When an elephant is shot in Africa the flesh is cut into strips and dried; it is then called "biltong." The elephant's foot is cut off from the knee joint, and a hole about 3ft. deep is dug in the earth, and the sides baked hard with burning wood. Most of these faggots are then removed, and the elephant's foot placed in the hole. It is filled up with earth tightly packed down, and a blazing fire built on top, which is kept burning for three hours. Thus cooked, the flesh is like a jelly, and can be eaten with a spoon. It is the greatest delicacy which can be given to a Kaffir.

Rhinoceros meat is something between pork and beef, and is not to be despised when no other flesh is to be obtained. In America a 'possum is esteemed a great delicacy. Kept in a barrel for a week and fed on sweet potatoes, and, when killed, stuffed and roasted, it forms a most delicate dish, resembling chicken in taste. A negro will spend all the night catching a 'possum for his Sunday dinner. Monkey meat is also good eating. Dr. Wallace, the well-known scientist, once breakfasted on monkey. "It was by no means bad," he wrote, "being something like rabbit." He also stated that: "Although the habits of the jaguar are filthy in the extreme, jaguar steaks are beautifully white, and remarkably like veal in taste." In the same way ducks, though feeding on grubs, worms, frogs, and mud, form, as everyone will admit, a delicious dish. Kangaroo steaks are splendid, and our Australian cousins assert that kangaroo soup is the finest in the world, and infinitely superior to ox-tail. Travellers are also unanimous in declaring that the flesh of the alligator and crocodile is extremely tender, white, and delightful to the palate. Seal flesh, though perfectly black, is matchless for flavour, tenderness, digestibility, and for heat-giving power. Squirrels are extensively eaten in some parts of rural England. Skewered nightingales is the great dish of Florence, and those who have conquered their sentiments and eaten the little songsters are loud in their praises. In Florida a stew of robins, jays, and bluebirds forms a most savoury and delicate dish, and if you did not know the names of the dishes, you could eat and enjoy rat pie, stewed cat, boiled horse-beef, fried snails, or any of the above dainties. As it is, the imagination is the autocrat of the stomach, and people will only eat what custom has made familiar. There is no reason—beyond that of custom—why man should not add some of the above dainties to his bill of fare.—*St. Louis Globe-Democrat.*

ARTIFICIAL PRODUCTION OF INDIARUBBER.

THE *Kew Gardens Bulletin* contains an article on Dr. Tilden's Artificial Production of Indiarubber, and quotes from his paper on the Spontaneous Conversion of Isoprene into Caoutchouc, read before the Birmingham Philosophical Society.

Indiarubber, or caoutchouc, is chemically a hydrocarbon. But what is called its molecular constitution is unknown. All that has been ascertained is that when decomposed by heat (distillation in closed vessels) it is broken up into simpler hydrocarbons, amongst which is isoprene. Isoprene is a hydrocarbon which was discovered by Greville Williams many years ago among the products of the destructive distillation of indiarubber. Later, in 1884, it was observed by Dr. Tilden among the more volatile compounds obtained by the action of a moderate heat upon oil of turpentine and other terpenes. It is a very volatile liquid, boiling at about 36°. Its molecular formula is C_5H_8, and it forms a tetrabromide, $C_5H_8Br_4$, but no methylic derivatives like the two homologues of acetylene.

Bouchardat observed that when isoprene is heated to a temperature near 300°, it gradually polymerises into a terpene, which he called diisoprene, but which is now called dipentene. This compound boils at 176°. A quantity of colophene, similar to that which is produced by the action of heat upon turpentine, is formed at the same time. When isoprene is brought into contact with strong acids, aqueous hydrochloric acid for example, a small portion of it is converted into a tough elastic solid, which has been examined by G. Bouchardat and by Dr. Tilden. It appears to be true indiarubber.

Specimens of isoprene were made from several

terpenes in the course of Dr. Tilden's work on those compounds, and some of them have been preserved. He was surprised at finding the contents of the bottle containing isoprene from turpentine entirely changed in appearance. In place of a limpid colourless liquid, the bottle contained a dense syrup in which was floating several large masses of a solid of a yellowish colour. Upon examination this turned out to be indiarubber.

The artificial indiarubber, like natural rubber, appears to consist of two substances, one of which is more soluble in benzene or carbon bisulphide than the other. A solution of the artificial rubber in benzene leaves on evaporation a residue which agrees in all characters with a similar preparation from Para rubber. The artificial rubber unites with sulphur in the same way as ordinary rubber, forming a tough elastic compound.

The constitutional formula of isoprene is now known to be:—

Methyl-crotonylene, $CH_2 = CCH_3 - CH = CH_2$.

In a recent letter, Prof. Tilden states:—"As you may imagine, I have tried everything I can think of as likely to promote this change, but without success. The polymerisation proceeds *very* slowly, occupying, according to my experience, several years, and all attempts to hurry it result in the production, not of rubber, but of 'colophene,' a thick sticky oil quite useless for all the purposes to which rubber is applied."

A 240-GEAR WHEEL.

ONE of the largest geared wheels ever built has just been completed, according to the New York *Sunday World*, by H. Fox, of 2,764, Boulevard, New York.

Its front sprocket contains 60 teeth and the rear sprocket seven; that is to say, the wheel is geared to 240. It is equivalent to an old-fashioned high bicycle equipped with a front wheel 20ft. high.

Assuming a running horse's stride to be 15ft., it must, in order to do a mile in 1·39, make over three and a half strides a second.

A man in doing a mile on the bicycle would only have to make a revolution of the pedals once in one and one-fifth seconds to beat the horse badly; or, to do a mile a minute, one revolution every three quarters of a second.

This wheel was built for Fisher, a Harvard man, who is engaged to ride it against some of the fastest horses on the French tracks at the Paris Exposition in 1900.

COMBINED DEVELOPMENT AND FIXATION.[*]

PUNNETT pointed out that chloro-bromide plates could be simultaneously developed and fixed. Hanneke has also written concerning similar experiments with bromide plates in the *Photographische Mittheilungen*, 1899, p. 141. The developing power of alkaline pyrocatechin upon bromide of silver is very little affected by hyposulphite of soda, and the quantity of the latter may be so far increased in relation to the former that development and fixation with a single solution may be effected in a few minutes. Theoretically, the matter is very interesting. But efforts are now being made, in Germany, I believe, to apply it practically, and under the name of "Elconal F." a strong, concentrated, fixing developer has been placed upon the market and sold in Vienna. Messrs. Elion and Co. have patented the process, but grant the right to use it to each purchaser of Ellon's pyrocatechin. The formula is as follows:—

No. 1.

Water	250 c.c.
Hyposulphite of soda	50 grammes

No. 2.

Water	75 c.c.
Sulphite of soda	30 grammes
Caustic potash (pure—in sticks)	7 ,,
Pyrocatechin	7 ,,

For developing and fixing a normal plate 13c. by 18c., take 12c.c. of developer No. 1, 20c.c. of fixing solution No. 2, and 30 c.c. of water. The process of development and fixation are simultaneous. We mention this novelty, as in some quarters it is spoken of as a great advance in photographic development.

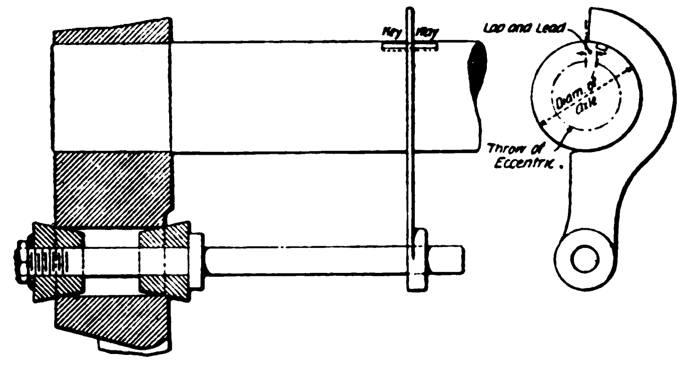
In our opinion the new method is very questionable. It is well known that the duration of development must depend upon the exposure, the lighting, and the nature of the subject; also that the temperature of the developer and many other subsidiary circumstances play a part. The fixing process proceeds independently, but the rapid interruption, or the prolongation of the development process, which are such important factors for the success of a fine negative in the hands of a competent photographer, become an impossibility.

It seems superfluous to demonstrate further to the professional photographer that combined development and fixation cannot be regarded as advance, and that it is not destined to replace the separate development and fixing processes in applied photography.

[*] By Dr. E. N. Eder, in the *Photographische Correspondenz*, translated in the *British Journal of Photography*.

LAYING OUT KEY-WAYS.

THE simple and convenient device illustrated by the accompanying engraving is used on the Baltimore and Ohio for laying out the key-ways on driving-axles, whereby the eccentrics are secured in position before the wheels are placed in position



under the engine. The drawing makes the method of operation clear with but little description. The spindle which carries the two conical plugs is self-centring in the crank pin-hole in the driving-wheel, and on the end of this spindle is an arm which partially encircles the axle. From this the key-ways are laid off with the proper angular advance. This device has been used for several years with very satisfactory results.—*American Engineer*, N.Y.

THE RELATIONS OF PHYSICS AND ASTRONOMY TO THE DEVELOPMENT OF THE MECHANIC ARTS.[*]

IT is but four months since, on January 18, you celebrated the seventy-fifth anniversary of the Franklin Institute. This is, therefore, an anniversary year, and it will not be long before January of the year 1906, when you will have an opportunity to celebrate the two hundredth anniversary of the birth of Benjamin Franklin, whose name is held in reverence and inscribed above your portals. You now propose to inaugurate a new branch of activity for the Franklin Institute. Not long since you added the Mechanical and Engineering Section to those already existing, and you have now added a fifth, to be entitled "The Section on Astronomy and Physics." The organisation of the Franklin Institute will, therefore, hereafter include, not merely a "Committee on Science and the Arts," and "Sections on Engineer and Mining and Metallurgy," but also special sections on important branches of science, such as astronomy, general physics, electricity, and chemistry. You have thus recognised the existence of certain relations between the advanced sciences and the practical arts. The Franklin Institute is devoted primarily to the promotion of the mechanic arts, but you have recognised that the sciences are so closely related to the mechanic arts that it is to your advantage to give them a distinct recognition in your organisation.

I.—The Mechanic Arts Closely Related to Physical Sciences.

This inaugural meeting of your new scientific section is, therefore, an appropriate occasion on which to consider with some detail the precise character of the relation between physics and the mechanic arts. I do not say astronomy and physics, because that branch of astronomy which we shall consider is itself known as celestial physics. We have celestial and terrestrial and molecular physics, three branches of knowledge that are all included under the comprehensive term physics, or the science that treats of force. Ages ago man recognised only those forces in which large masses of matter are involved. He studied projectiles, falling bodies, the equilibrium of forces, the buoyancy of vessels, the motions of waves and tides and winds, and even the motions of the heavenly bodies. But now he has learned that all chemical phenomena have to do with the motions and equilibrium of molecules; that heat and light and electricity and the photographic or chemical action of light are but the motions of individual molecules of ponderable matter, and of the imponderable ether atoms that drive the material molecules hither and thither; that sound is but the motion of larger groups of molecules. Everywhere he is confronted by the laws of force. If you strike a smart blow with a hammer upon the head of a cold chisel and make a cut into a piece of soft iron, you are doing one of the simplest mechanical operations, and yet you are awakening a long list of reactions that invade every branch of physical science:—1. The muscles respond to the eye and the will; the hammer moves with great acceleration, and strikes straight and hard; the energy of the blow comes from the chemical transformations going on within the workman's body, suggesting problems that belong to the profoundest depths of biology. 2. The stroke of the hammer calls forth a clear and cheerful sound from the head of the chisel—a musical ring with all its problems in acoustics. 3. The hammer, the steel chisel, the soft iron, and the chips become warm and hot under the repeated blows, suggesting problems in thermodynamics and the radiation and conduction of heat. 4. The edge of the hard chisel becomes dull, but a deep gash is cut in the soft iron; eventually the face of the chisel breaks; all of which results are explained by the study of the science of elasticity as applied to the flow of solids and the exhaustion of metals. 5. A better chisel is picked out and the hammering goes on all day without harm to the tool; such choice could not be made without a thorough knowledge of the chemisty and physics of steel. 6. If the anvil be a stone and both it and the hammer be properly insulated and connected with an electrometer, every stroke would be seen to produce electricity; this sets us to thinking about piezo-electric phenomena, and we perceive that as every change of pressure produces electrical phenomena, therefore the electrified condition of the whole earth, with its resulting atmospheric lightning, may be in part the result of the crunching of the geological strata that we call the earthquake, an idea that was first suggested by Clerk Maxwell. I need not weary you with illustrations of that which must be patent to every thoughtful mind; the general principle holds good everywhere and at all times that no invention can be made, no action taken, no great work accomplished on this earth, without involving many principles in nature that have already been recognised by scientists and others that still remain to be discovered. You, therefore, do well to combine both physical science and the mechanical arts into one institution. Your object must be, on the one hand, to apply physics to the proper construction of machines and the daily needs of the artisan. On the other hand, you may hope to add something —perhaps much—to our knowledge of physics, through your ingenious machinery, your abundant experience, and your keen thought. The manifold and intricate connection between the sciences and the arts may be treated from several points of view. Let us first glance at the historical development of this connection.

II.—Evolution of the Mechanic Arts.

The mechanic arts may be said to have existed before the dawn of history; they were coeval with the evolution of the Aryan language. We trace the art of weaving, as we now know it, back to the time, 3,000 years ago, when it was already well advanced in India, but the word *to weave* is far older than that. We trace the potter's wheel back to the earliest archæological potsherds, perhaps 5,000 years, and know nothing of its far earlier history. We trace the arts of cutting, sawing, and planing from our present magnificent machinery back to the first knives of jade used by the prehistoric Asiatic and American races. We trace our hoes, ploughs, and cultivators back to the sticks and the forked branches that were used to scratch the soil by the first tribes of men, but how many thousand years ago no one ventures to say. The modern railroad car, the elegant waggons and the fleet bicycles only became possible after the ancient architects had first learned to put rollers under the massive stone blocks and had put rude wheels to the carts drawn by oxen and to the wheel-

[*] By Prof. Cleveland Abbe, U.S. Weather Bureau, Washington, D.C., an address delivered before the Franklin Institute.

barrow pushed by man. The art of sewing leaves together, or that of spinning threads must have been an early suggestion after man had learned to twist grass and twigs together to form crude ropes. Our extravagant military engines, from the immense ironclads down to the Mauser rifles, go back step by step to the stones and slings, the bows and arrows, and the boomerangs of primitive man. I should say that the mechanic arts had no definite beginning; they have gone through a process of evolution so gradual and gentle that we can at no time say "this was the beginning." Mythology does, of course, tell us that Vulcan forged Jove's thunderbolts. To the mind of the child of to-day, just as to the childish minds of antiquity, everything on earth must have had a definite beginning—there must have been someone who first taught us how. Therefore the ancients demanded a cosmogony, a History of Beginnings, a Divine Creator, and a simple tangible method of procedure as to His inventions and creations. But the modern scholar who has studied carefully all the ways of nature among the plants, animals, and rocks of this earth and the stars of the universe beyond us, perceives that a series of changes, a gentle and gradual evolution, has prevailed everywhere. We are, therefore, prepared to recognise that this same principle applies to the industries and to the arts that have been developed through the agency of man. We are but the agents. The Creator is working, but through us, not for us. He moulds the world, not as the potter does the inert clay, but as the wise parent does the mind of the intelligent child.

III.—Evolution of Inventions.

The crude devices of primitive man were improved by successive inventions. In the history of invention, properly so-called, the simple collocation and juxtaposition of two ideas is often the critical matter. It is not science, or study, or art—it is simply the happy accident that brings someone's mind two thoughts that are suddenly seen by the inventor to have an important relation to each other hitherto unsuspected. For instance, someone is anxiously looking about for a pigment that will produce a special tint of colour. He is wandering along the roadside and sees the colour he needs in a piece of stone or discolouring a ledge of rock. If his mind is ready to receive the suggestion, it becomes seed sown in good ground. The idea of grinding that stone into pigment immediately occurs to him. He proceeds to experiment, and not only grinds, but oxidises and even roasts the stone. The invention was a matter of suggestions to the inquiring seeker, but the art was an application of physical and chemical science. Man's needs have stimulated him to discover and invent. Those who enjoyed the best surrounding have generally brought forth the best results. Those nations and individuals who were unfortunate as to climate, soil, vegetation, minerals, water-power, &c.—those who had neither stimuli nor opportunities, did little. In proportion as we to-day associate ourselves with the highest science, we bring forth the best inventions and manufactures. Someone asks why we cannot make a steamboat that will go fifty miles an hour by the use of the screw-propeller. The idea is good, but it is a mere matter of imagination, a dream, a useless suggestion until all the resources of physics and mechanics have been combined to evolve the modern high-speed vessel. Prof. S. F. B. Morse was an artist, but was also seeking to make some great invention. The idea of communication by means of electricity, with the speed of thought, early took possession of his mind, and he was always on the look-out for some method of realising the indefinite hope that haunted him. Ten years were spent in making every conceivable combination of electrical devices—but nothing came of them. At length Dr. L. D. Gale suggested that Joseph Henry's recent researches on the electro-magnet be put to use. That distinguished scientist was consulted at Princeton, and immediately it was found that the laws that he had discovered in relation to electricity and magnetism, and the apparatus that he had made, were those appropriate to the Morse telegraph, that, in fact, he had one already at work. Even if you do not agree that we ought to speak of the "Henry telegraph" and the "Morse alphabet," you will at least grant that every step in telegraphy, from its beginning to the modern perfection of the art, has only become possible by means of the knowledge resulting from investigations conducted by scientists, or by inventors who had to become scientific investigators before they could complete their work.

IV.—Invention Associates with Investigation.

We must be careful to recognise that the inventor is frequently also a scientist, and still more frequently is the scientist an inventor. The scientist cannot investigate without having instruments and apparatus, and must invent these to suit the needs of the case. The inventor frequently comes upon an obstacle that cannot easily be overcome until he has investigated some obscure point either in mechanics or physics. This principle is beautifully illustrated by the life and work of James Prescott Joule, who was the son of a brewer, and himself continued in that business for a long time. His scientific education under Dalton, in England, and Jacoby, in St. Petersburg, enabled him to fully appreciate the mutual relations of science and art. While others speculated on the use of the electricity from the galvanic battery as a motor, he, by studying the laws of thermo-dynamics, showed the exact connection between the amount of work that could be done by a pound of coal when burned in the furnace and a pound of zinc consumed—i.e., burned, in the galvanic battery. He then proceeded to the determination of the so-called "mechanical equivalent of heat"—viz., the fact that a unit of heat can only do 772ft.-lb. of work. He is justly considered one of the founders of the modern doctrine of the conservation of energy, whose principles must be obeyed by every mechanical device that man can invent. When anybody proposes to manufacture something out of nothing, no matter whether he calls it perpetual motion, or the Keely motor, or the liquid-air motor, you have only to show him that he proposes to violate Joule's law and he must subside. The changes of temperature produced by condensation and rarefaction of gases, especially of steam, are vital to the working of the steam-engine. These were early experimented upon by Espy, but more thoroughly by Joule and Kelvin; the arrangement of the cut-off of the steam-engine must be made in accordance with Joule's laws if the machine is to work efficiently, as indeed he, himself, first showed in his paper of June, 1844. At that time he said: "The principles I have established lead to a theory of the steam-engine very different from the one generally received. . . . Believing that the power to destroy belongs to the Creator alone, I entirely coincide in the opinion that any theory which, when carried out, demands the annihilation of force, is necessarily erroneous. . . . The theory here advanced demands that the heat given out in the condenser shall be less than that communicated to the boiler from the furnace in exact proportion to the equivalent of mechanical power developed."

V.—Mechanics, Experimental and Empirical, Associates with Science.

I choose the following case to illustrate this theorem:—In the *Philosophical Transactions* of the Royal Society of London for 1866 is a beautiful memoir on the theory or method of action of lubricating oils and other lubricators. This memoir, by Prof. Osborne Reynolds, seems to be the first satisfactory effort to unravel the physical actions involved in lubrication. There had been abundance of previous experimentation for 200 years past, and many empirical rules and tables had been formulated respectively applicable to each set of experiments, but the special experiments made by Mr. Tower gave Prof. Reynolds the first suggestion as to the truth concerning the method of action of the film of oil that we insert between a journal and its bearings in order to diminish the loss of power by friction. Reynolds had previously conducted a beautiful set of experiments on the flow of liquids in tubes and very small channels, and had shown that, although the resistance to flow is ordinarily proportional to the square of the velocity, yet there is a critical velocity at which it suddenly changes from the square over to the first power of the velocity. He was now able to show that lubrication is simply a case of the flow of a viscous liquid through a very narrow channel. When the journal presses upon its bearing, the intermediate space is perhaps the $\frac{1}{1000}$in., or more likely $\frac{1}{10000}$in. in thickness. This space, being filled with oil, constitutes the thin film that serves to convert the rubbing and tearing of the metals into the sliding and rolling of liquid molecules. It is as though we had inserted a myriad of minute steel friction balls between the journal and its bearings. You are all familiar with the thin films of the soap bubble. Perhaps you have observed that when the film is not too thin it may be said to consist of two surface films separated by a thicker layer of liquid. These two surface films may slide past each other. By careful watching you may see the beautiful spots of coloured light re-arranging themselves as the two surfaces draw nearer and nearer together and squeeze out the liquid between them. The thinnest part of the soap bubble is a film much thinner than that ordinarily dealt with in lubrication, while, again, the thicker parts are much thicker than lubricating films. By means of the apparatus invented by Plateau, the properties of these thin films have been abundantly studied. The motions of the viscous liquid particles must obey the laws of mechanics, as at first clearly expressed by Stokes, Kirchhoff, Helmholtz, Stefan, and other students of hydrodynamics. The results of these difficult researches in molecular physics have a direct application to the lubricating action of oils. Prof. Reynolds succeeded in elucidating the novel phenomena recorded by Mr. Tower, and established an important verification of the assumptions on which our modern theories of hydrodynamics and molecular physics are founded. I may be allowed to speak more fully on this subject, because these ideas have not yet found their way into many textbooks on machinery. Let us take up one simple phenomenon—viz., the heating of the journal and bearings. We have hitherto imagined that after the journal has worn a smooth bed in its bearings, and there is no objectionable and injurious heating or abrasion, that then its rapid revolutions proceed without the evolution of much heat. Now the fact is, that while the upper and lower surfaces of the lubricating film of oil remain in permanent contact with the steel journal and the brass box respectively, or at least change very slowly, and there is no abrasion of the metals, still, the thin layer of intermediate liquid is being rapidly torn away and renewed. The viscosity of the liquid resists this sliding of one layer of its molecules past the other, and thus gives rise to heat. The inner layer of the liquid film soon becomes a surface layer where the molecules are under great tension, and this change gives rise to more heat. As long as the journal is revolving heat is being evolved by the compression and internal friction or motion of the molecules composing the lubricator itself. Often we do not observe this heat because it is carried away by conduction through the metals and by the last breath of air almost as fast as it is generated. Everyone knows that the abrasion of dry metal surfaces evolves heat, but the abrasion of viscous films also does so. As the journal revolves rapidly, it carries its thin film of oil into the crevice between the journal and the bearing; it is a V-shaped or wedge-shaped crevice, and as the film crowds into the wedge, Reynolds speaks of it as going into the "on" side, because right above this crevice is the load bearing down upon the film. As the film squeezes through the crevice, being forced along by the rotating journal, it quickly approaches the off side of the load, where the pressure is taken off of it and it is again free to spread out over the journal: thus it is carried around until it again enters the "on" side and squeezes through a second time to the off side. You will see at a glance that the small area of film between the journal and the bearing on the "on" side must support the whole load, and this implies an enormous pressure, which, in the experimental work of Mr. Tower, was only 625lb. to the square inch, but must be far greater than this in many of the cases that occur in actual practice. Of course, the laws that hold good for perfect lubrication will not obtain for the case of imperfect and irregular supply of oil, or for cases where the lubricant has not the proper molecular and physical properties needed when very great pressures are involved. But when there is a full supply of oil and the pressures are not too excessive, then you will easily perceive that the film adhering to the journal and about to enter the "on" side of the crevice is not as yet under any pressure or constraint, except only that it is held to the surface of the journal by reason of some molecular attraction between the metal and the liquid. Ordinarily, we say that the particles of liquid cohere among themselves, while the liquid and the solid adhere together. Now, the liquid will not easily be forced from the free surface of the journal into that crevice between the journal and bearing where the pressure per square inch is so great, and yet it does both enter and pass through, and there is nothing to bring about this remarkable result, except the rapid motion of the journal and the adherence of the film to its surface. We must think of the liquid film as a small mass of matter thrown into the "on" side of the crevice with considerable velocity and, also, as dragged in by the journal. Its viscosity and its inertia combine to force it into the wedge-shaped space. It must be very considerably compressed therein. It must, also, have its molecules forcibly squeezed past each other as it passes through the narrowest part of the wedge, and slips onward to the large space in the rear. Of course, also, its forward movement with the journal is slightly retarded in front and accelerated in the rear. But the most interesting feature is the pressure—the static pressure within every part of the film. There must be a resultant pressure against the surface of the bearing, and another against the surface of the journal. These would be normal to the surfaces, and equal in intensity and opposite in direction if the journal were not in rotation; but when rotating the pressure keeping the two surfaces apart is greatest in the front half of the lubricating film, while in the rear half it becomes negative—that is to say, it tends to bring the two surfaces together. This surprising result may, perhaps, be easily reconciled with our current ideas if we remember that the same powerful adherence which carries the oil with the journal forward into the funnel must also, in the rear of the latter, carry it away from the funnel. As much oil must leave the funnel in the rear as approaches it in front. There is a push in front, but an attraction in the rear. It is evident, therefore, that the force that keeps the journal from absolute welding contact with its bearing is the adherence of the oil to the journal and the coherence of its own particles.

The resistance that we call friction in a smooth-running journal is an exaggerated case of that which we call viscosity in hydrodynamics. It is the force required to make one layer of liquid glide past another. The other friction that occurs when no lubricant is used, or when the supply of the lubricant is too limited, of course, involves the tearing asunder of the particles or molecules of the metals themselves. This abrasion is not considered in the theory of lubrication. Prof. Reynolds' hydrodynamic theory, as checked by Mr. Tower's experiments, seems to give us a complete statement of the relation between the frictional resistance, the load and the speed for any lubricant that is supplied in abundance, and he has given us a general formula applicable to all cases that can occur. When there is but a limited amount of oil available, an increase in the load—i.e., the pressure—will diminish the thickness of the film around the journal in general: but will increase the length of the pad of oil that bears the weight, thereby increasing the area of the surface films, whose sliding past each other produces the frictional resistance, and, therefore, increasing the friction. The relation between the increase in friction and the increase in load for this case is more complicated than for the case in which an unlimited amount of oil is available, which latter case is experimentally realised by wholly immersing the journal and its bearings in a bath of oil. The result of the whole research is to show that, not only in case of intentional lubrication, but whenever hard surfaces under pressure slide over each other without abrasion, they are separated by a film of some foreign matter, whether perceivable or not; that the action of the revolving journal is to maintain the film between the surfaces at the point of pressure; that if there is any abrasion when the surfaces are well lubricated and well filled, it must be due to the foreign particles in the oil—particles introduced at the first grinding or subsequently as dust.

I may add that when the lubricant has thickened or is entirely absent, we have a condition analogous to that of the swiftly revolving wheel of soft lead, which is used to cut into the harder metals, to which I will refer later.

I give this long review of Reynolds' work as but one among many illustrations of the advantages that accrue to empirical mechanics when illuminated by sound science.

(*To be continued.*)

WHITWORTH SCHOLARSHIPS.

THE following is the list of candidates successful in the competition for the Whitworth Scholarships and Exhibitions, 1899:—

1. Scholarships (tenable for three years; £125 a year each):—

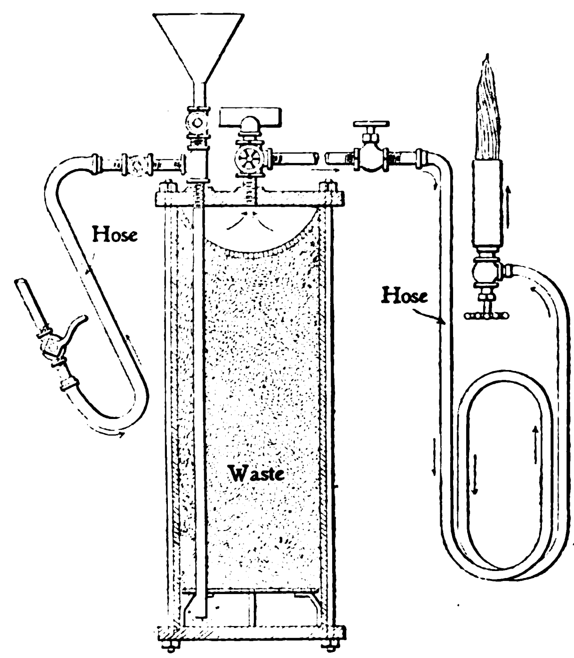
Name.	Age.	Occupation.	Address.
1. Quennell, A. W.	21	Engineer........	London
2. Topham, H.......	22	Engineer.........	Gt. Horton, Bradford
3. Shearer, W. V. .	21	Eng. Student...	Langside, Glasgow
4. Wall, G.	25	Student	Oldham

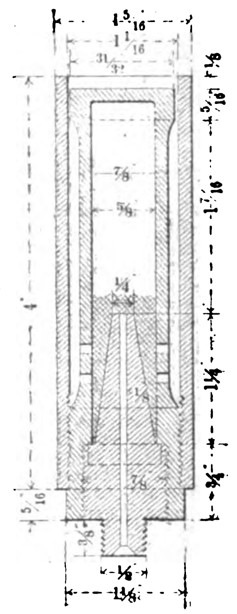
2. Exhibitions (tenable for one year; £50 each):—

1. Spencer, A. J. ...	20	App. Fitter......	Portsmouth
2. Turner, G. F. ...	23	Engineer.........	Sheffield
3. Philpot, H. P. ...	23	Draughtsman .	London
4. Adams, W. H....	19	App. Fitter......	Devonport
5. Moyle, E. C.......	19	App. Fitter......	Devonport
6. Scoble, W. A. ...	18	App. Fitter......	E. Stonehouse, Devon
7. Alexander, A. D.	18	App. Fitter......	Portsmouth
8. Edmonds, S. A..	18	App. Fitter......	Devonport
9. Cowley, G. F. A.	20	App. Fitter......	Portsmouth
10. Wilson, A..........	21	Draughtsman .	Leeds
11. Britton, E. J. ...	19	App. Fitter......	Portsmouth
12. Duncan, H.	20	Engineer.........	Plumstead
13. Rhodes, S. C. ...	20	Engineer.........	Morley, Leeds
14. Andrew, H. M....	22	Fitter	Manchester
15. Traill, A. P.......	21	Draughtsman .	North Shields
16. Bairstow, L.......	18	Student	Halifax
17. Butlin, W. T. S.	23	Student	Bristol
18. Dodridge, A. E. .	19	App. Fitter......	Devonport
19. Lowe, J.	22	Draughtsman .	Alloa
20. Rodd, W. J.	20	Mech. Engineer	Plumstead
21. Rendle, F. C. ...	23	Fitter	Plymouth
22. Heywood, T. E. .	21	Eng. Student...	Cardiff
23. Paul, J.	23	Engineer.........	Woolwich
24. Raitt, C. P.	20	App. Fitter......	Portsmouth
25. Booth, C. H.......	18	App. Engineer .	Bolton
26. Howarth, E.......	20	Fitter	Oldham
27. Down, P.	22	Draughtsman .	London
28. Straw, M. H. ...	25	Draughtsman .	Sneinton, Nottingham
29. Matthews, R. B..	21	Engineer.........	Swansea
30. Crossley, S.	23	Mechanic	Oldham

PAINT BURNER.

THE annexed illustration shows a very successful form of paint burner which is used by the Southern Railway. The reservoir is 36in. long by 12in. in diameter. It is completely filled with clean waste, packed as tightly as possible. The reservoir has a false bottom and top, both of which are perforated. The air pipe extends into the space between the false and true bottom, and the air becomes thoroughly saturated with gasoline, with which the waste is saturated, before it reaches the corresponding space at the top into which the discharge pipe enters. An interesting feature here is the use of a pressure gauge upon the discharge pipe, and a valve at this point for controlling the supply.





The burner is of peculiar construction, and is designed with a view to still further mingle the air and gasoline. The supply enters the burner through a nipple, having an aperture $\frac{1}{8}$in. in diameter. This nipple is inclosed in a cap, having its outer extremity closed, but with a series of perforations below the tip of the nipple. There are 35 of these perforations, $\frac{1}{8}$in. in diameter, in four rows staggered. The inside of the cap is lined with a fine-mesh brass-wire netting, covering the perforations. Outside of all is a shell 4in. in length and extending $\frac{1}{8}$in. beyond the end of the cap described. The outer circumference of the cap is flared near the end, so that the only place for the escape of the gas is an annular space $\frac{1}{32}$in. wide between the cap and the shell.

The course of the mingled air and gas in the burner is from the nipple to the closed end of the cap, back through the netting and perforations, and through the narrow space inside the shell to the end of the burner. The gas and air become so thoroughly mingled that the combustion is nearly perfect, and the flame is almost entirely blue.—Frank Johnson, in *Locomotive Engineering*, N.Y.

MILK PRESERVATIVES.

OUT in Omaha it has been found that dairymen are using a "patent fluid" to prevent milk spoiling. A spoonful of the antiseptic, which is sold for three dollars a gallon, keeps a can of milk for several days. Children are dying from the use of this milk—so it is reported.

Among the milk preservatives, which include salicylic acid, borax, and boric acid, the disinfectant formaldehyde is the newest, and it is probable that the Omaha "preservaline" is a preparation of formaldehyde. Not long ago the New Jersey State Health Department prosecuted some thirty or more dairymen for using formaldehyde.

Very little of this antiseptic or any other has been used by dairymen who send milk to this market, undoubtedly because the farmers fear the New York Health Department. The Sanitary Code says that nothing must be added to or taken away from the pure milk as it comes from the cow.

Dr. Ernst J. Lederle, consulting chemist to the Health Department, has found some use of antiseptics in New York milk. Their use in milk, he says, should be absolutely prohibited. They interfere with digestion, and may do great injury to infants and invalids.—*Practical Druggist.*

DEATH OF PROF. BUNSEN.

BY the death of Robert Wilhelm Eberhard Bunsen, F.R.S., &c., science has lost one of the most famous chemists the world has known, and Germany one of her most illustrious sons. His father was a distinguished theologian of Göttingen, in which city Bunsen was born in 1811, and graduated at the University (which, by the way, was founded by George II. of England) as Ph.D. at the age of twenty. After spending a few years in study at Paris, Berlin, and Vienna, in 1836 he succeeded Wöhler as Professor of Chemistry in the Polytechnic School at Cassel. Two years later he went to Marburg; then, in 1852, after a short interval at Breslau, he was appointed to the chair of experimental chemistry at Heidelberg, where he remained, in spite of a tempting invitation to Berlin University, until his resignation in 1889. Many academical distinctions, of course, fell to his share, both in this country and abroad. In England the Royal Society—which in 1858 elected him one of its foreign members—awarded him the Copley medal in 1860, and seventeen years afterwards chose him and his fellow-worker Kirchhoff to be jointly the first recipients of the Davy medal.

He first showed his ability in the prosecution of a difficult and dangerous investigation upon a series of poisonous and explosive organic compounds of arsenic, and in the course of these experiments he met with an accident which nearly cost him his life; but, undaunted, he pursued his work until he succeeded in placing the chemistry of the whole subject in a clear light. The discoveries in almost every branch of chemistry made by his unwearied assiduity would fill a treatise. The Bunsen voltaic battery, which supplanted the more expensive form bearing the name of Grove, was generally used as the cheapest and most effective mode of generating electricity until the dynamo displaced all forms of batteries. Then came the Bunsen gas-burner, which, it is not too much to say, is now not only a necessity in the laboratory, but in every household and every manufactory where a clean flame is wanted. About his discovery of this simple and effective apparatus an interesting tale could be told, says the *Times*. No one before Bunsen had thought it possible that a mixture of coal-gas and air could be made to burn without explosion from a simple tube burner. His clear conception of the laws which apply to the inflammation of such a mixture showed him that it was possible to arrange the dimensions in such a way that a steady, smokeless, and highly combustible mixture could be obtained; but a long series of delicate experiments was needed before the perfect burner which now bears his name resulted. Of other investigations carried out by Bunsen may be mentioned those on the chemistry of blast-furnace gases, in conjunction with the late Lord Playfair, on actinometry and the chemical action of light with Sir Henry Roscoe, and on the geological conditions of Iceland and the theory of the geysers, the result of a visit to that island in 1847.

The research, however, by which, perhaps, more than any other the name of Bunsen will go down to posterity, linked with that of his colleague Kirchhoff, is the discovery of spectrum analysis, for this opened out a field of experiment so new and so vast that it may well be said to be the most important scientific result accomplished during the latter half of the century—a time pregnant with work of a truly marvellous character. To have added a new branch to chemical science which throws a clear and wholly unexpected light upon the constitution of terrestrial matter, which has been the means of discovering many new chemical elements, and of proving the widespread distribution of others hitherto considered as rare, would in itself have been a work of primary significance; but when to that is added the fact that by means of this far-reaching method the bounds of our planet are outstepped and a knowledge not only of the chemical composition of the sun and of the far-distant stars but even of their rates of motion have thus been

obtained, an idea may be formed of the debt of gratitude which all interested in human progress must feel to the two great twin brethren who, in their quiet laboratory at Heidelberg, revealed such hidden secrets. But these, though the best-known and most popular of the achievements of the Heidelberg master, are not more important from a scientific point of view than many others all known and valued by the chemist and physicist. To have first instituted methods of almost astronomical precision in the measurement and separation of gases, and thus to have laid on a firm foundation the branch science of gas analysis, is in itself sufficient to have marked him as one of the first experimentalists of the age. Add to that his numerous memoirs on purely chemical subjects, all marked by the same accurate work; add, again, his researches in physical chemistry; on the measurement of the chemical action of light—carried on in conjunction with one of his pupils—and, again, one on a new and improved method of determining specific heat, not forgetting his chemico-geological researches, which constitute what may well be termed an epoch-making discovery as to the composition of the volcanic rocks of our planet, and it is not much to say that for variety and importance the theoretical and experimental work proceeding from his brain and hands has rarely, if ever, been exceeded.

This work, although great, is by no means the only or even the greatest work achieved by Bunsen. He has built up a vast and enduring reputation by his labours as a teacher and as a master craftsman.

USEFUL AND SCIENTIFIC NOTES.

A NEW form of caisson for executing work under water, the invention of the Russian engineer, L. Astarchoff, is about to be tried in the Neva by a committee of technical experts. The caisson in question has a conical form, and its inventor claims that, by its use, work can be carried on on the bed of a river at a lower atmospheric pressure than is now the case with the present caissons.

Royal Exhibitions, National Scholarships, and Free Studentships (Science), 1899.—The following is the list of successful candidates:—Royal Exhibitions: William M. Selvey, 18, apprentice fitter, Devonport; Edward C. Moyle, 19, apprentice fitter, Devonport; Archibald D. Alexander, 18, apprentice fitter, Portsmouth; Charles W. Price, 18, apprentice fitter, Devonport; George F. A. Cowley, 20, apprentice fitter, Portsmouth; Edgar Sutcliffe, 16, student, Blackley, Manchester; Sydney A. Edmonds, 18, apprentice fitter, Devonport. National Scholarships for Mechanics (Group A): Francis P. Johns, 20, apprentice fitter, Devonport; George F. Turner, 23, engineer, Sheffield; Walter A. Scoble, 18, apprentice fitter, East Stonehouse, Devon; Arthur J. Spencer, 20, apprentice fitter, Portsmouth; William H. Adams, 19, apprentice fitter, Devonport. Free Studentships for Mechanics (Group A): R. Borlase Matthews, 21, engineer, Swansea; William H. Outfin, 19, apprentice fitter, Devonport. National Scholarships for Physics (Group B): William R. Daniel, 16, student, Levenshulme, Manchester; William J. Lyons, 21, science teacher, Cork; James Lord, 20, student, Chadderton, Oldham; William M. Varley, 20, student, Slaithwaite, Huddersfield; Wilfred H. Clarke, 21, science teacher, Kidderminster. Free Studentships for Physics (Group B): John H. Shaxby, 19, Aberystwyth; †Gerald Henniker, 17, student, London. National Scholarships for *Chemistry* (Group C): William D. Rogers, 17, assistant science teacher, Smethwick; John H. Crabtree, 24, cotton weaver, Todmorden; Howard E. Goodson, 18, laboratory assistant, Armley, Leeds; Arthur H. Higgins, 18, student, Bradford; Montague W. Stevens, 17, student, Plymouth. Free Studentships for Chemistry (Group C): John R. Horsley, 16, student, Canterbury; †Arthur C. Nicholson, 20, student, Newark. National Scholarships for Biology (Group D): Eric Drabble, 22, student, Chesterfield; Louis E. Robinson, 17, student, Bradford; Ernest A. Wraight, 20, London; Reginald F. G. Bayley, 19, Eltham; *Harold B. Fantham, 22, teacher, Birmingham. National Scholarships for Geology (Group E): William H. Goodchild, 19, analytical chemist, London; Thomas Thornton, 22, cloth looker, Briercliffe, Burnley.—(* Extra Scholarships transferred from Group E. † Extra Free Studentships transferred from Groups D and E.)

SCIENTIFIC NEWS.

THE programme of the British Association, which meets at Dover on Sept. 13, under the presidency of Sir Michael Foster, Sec. R.S., has been issued, and to a certain extent is of special interest, as the meeting this year partakes of an international character. The members of the French Association will visit Dover on Sept. 16, and the members of the British Association are invited to visit Boulogne on the following Thursday. It is anticipated that the gathering will be memorable by the large attendance of the most eminent men of science in America and on the Continent. The Mayors and Corporations of Dover and Canterbury, the military authorities of the South-Eastern District, and the leading scientific and educational institutions, will take part in the entertainment of the Association. The Castle at Dover and National Harbour Works will be open for inspection during the meeting. The first general meeting will be held at the Connaught Hall on Wednesday, Sept. 13, when Sir Michael Foster will assume the presidency in succession to Sir William Crookes, and deliver his Presidential address. On the following evening there will be a soirée in the School of Art, and on the Friday evening Prof. Charles Ritchet will deliver an address on "La Vibration Nerveuse." The professor next evening will discourse on "The Centenary of the Electric Current." In the Mathematical and Physical Science Section Prof. J. H. Poynting will preside; in the Chemistry Section the president will be Mr. Horace T. Brown; and the presidents in the other sections will be: Geology, Sir Archibald Geikie; Zoology, Mr. Adam Sedgwick; Geography, Sir John Murray; Economic Science and Statistics, Prof. Henry Higgs; Mechanical Science, Sir W. H. White, Chief Constructor of her Majesty's Navy; Anthropology, Mr. C. H. Read; Physiology, Mr. J. N. Langley; Botany, Sir George King; conference of delegates and corresponding societies, Rev. T. R. R. Stebbing. A special feature of the Association will be demonstrations of Signor Marconi's wireless telegraphy, and the Rev. Mr. Bacon, it is anticipated, will give an address on his recent balloon experiments.

Observations of the Perseids seem to have been fairly successful this year, and it is probable that when all the notes come in some useful data will be obtained.

Dr. Frank Schlesinger, of Columbia University, New York, is to take charge of the observations on variation of latitude at Ukiah, California, under the scheme of the International Geodetic Association.

In France the finance minister has granted to MM. Hermite, of Besançon, the sum of £50 towards the expenses of making experiments with free balloons. Some of these experiments will be made at Boulogne during the meeting of the French Association for the Advancement of Science.

Dr. Daniel G. Brinton, the distinguished American anthropologist is dead, in his sixty-third year. He was for many years Professor of American Archæology and Linguistics in the University of Pennsylvania, and has bequeathed his valuable library to that institution. Dr. Brinton had very little work to do in connection with his professorial duties, and had therefore so much time to devote to research that he became the most accomplished man in America in connection with the many languages of that vast continent.

The death is announced of Mr. Thomas Francis Rivers, of Sawbridgeworth, Herts, who was well known throughout the civilised world as one of the most successful of the modern professors of fruit culture.

According to a Reuter's telegram which deals with other matters, Capt. Welby has made an important expedition in Abyssinia and the regions to the south-west. After some preliminary excursions, it appears that Capt. Welby collected a "caravan" and then struck south, skirting the western shores of the Abyssinian lakes. The last of these, Lake Obai, is surrounded by mountains over 10,000ft. in height. The country from this point was practically unexplored. Capt. Welby found it very fertile and thickly populated by Gallas, who are tributary to the Abyssinians. It is purely agricultural, and the natives, many of whom had never seen a white man before, were everywhere friendly. Leaving this region, the party continued their journey to the north end of Lake Rudolph, Capt. Welby being able to satisfy himself that the River Womo runs into that body of water. The east shore of the lake, which was next visited, was found to be practically uninhabited. Here the great majority of the caravan animals died of anthrax. One tribe met with—the Tirkana—were of immense stature, most of the men being 7ft. in height. They had long hair extending to the waist, and matted like felt. This they generally wear turned up in such a manner as to form a receptacle for small articles and nick-nacks, the ends being finally twisted into a tail with a thin stick, about which they are very particular. Abundance of game was met with, and elephants were numerous. The chief articles of commerce in the new region explored are camels, donkeys, sheep, and agricultural produce, brass, iron, copper, and amber. No precious metals were seen, but there is a large supply of white marble. Payments are made in beads, salt, and iron bars.

It is announced that Mr. Weld Blundell and Lord Lovat have presented to the British Museum the fine collection of birds made by them during their recent expedition through Southern Abyssinia to the Blue Nile. They travelled through nearly 300 miles of country which had never been previously explored. The collection is said to be one of the most interesting that has ever been obtained in Abyssinia, and is remarkable for the number of species it contains new to science. A detailed examination has not yet been made, but at least twenty new birds have been discovered by the ornithologists of the Museum.

The neighbourhood of London has been infested with mosquitoes during the hot weather, as have most ports to which ships from the Tropics come; but the sting of these mosquitoes is not so bad as that of the malarial mosquito, which it is announced that Dr. Ronald Ross has found. He was sent out by the Liverpool School of Tropical Diseases to study the subject, and to determine which species of mosquito is the disseminator of malaria.

Some rather extraordinary statements are made as to Marconi's system of wireless telegraphy, and it is said that the possibility of communicating with the United States has been almost demonstrated. It appears that messages have been sent and received from stations between which some miles of cliff 400ft. high intervened, and it is considered settled that messages can be sent from Paris to London, and that it is probable they can be sent from England to America. When the British Association meets in Dover next month experiments are to be made, and attempts will be made to signal over very great distances.

It is stated that Signor d'Azar's maritime telephone consists of two sections, or "sound collectors," one of which is lowered into the water on each side of the vessel, both being connected by a special mechanism to a microphone provided with a vibrating membrane. A movable hand indicates the direction of the sound-waves upon a quadrant, which is placed on the deck, so that it is quite possible to learn the approach of a vessel and its course at a distance of five miles in the darkest night or thickest fog. Should two vessels wish to communicate with one another, they need only make use of a special clapper-apparatus, the strokes against the side of one vessel being registered on a Morse machine in the other. All semaphores along the coast can also communicate with ships at sea by means of specially-constructed buoys. Apparently it is an important invention, but further details will be awaited with interest.

At the meeting of the Iron and Steel Institute the important question of carburised iron was brought up by Dr. A. Stansfield, who said that metallic alloys behaved as saline solutions did, and bringing carburised iron into line with alloys was rendering a good service to industrial and theoretical chemistry. A solution need not be a liquid, but in certain solids, especially when they were at a high temperature, an added element tended to diffuse itself uniformly through the mass, from which, however, as from the liquid solution, it might be crystallised out on cooling. Such a solution was white-hot steel. The solution theory of carburised iron affirmed that this substance was, when fluid, a solution of carbon in iron, and that under certain conditions the solidified mass also formed a solid solution. It

further affirmed that these liquid and solid solutions obeyed the ordinary laws of solution, which had been fully studied in the case of aqueous, saline, and organic solutions. The solution theory could, therefore, be invoked to explain both the mode of solidification of carburised iron, and the molecular changes that took place after solidification. The president expressed himself as being quite in accord with the author, who, he thought, had advanced the subject by his elaborate paper.

The autumn meeting of the Iron and Steel Institute appears to have been very satisfactory from all points of view, but the papers read were necessarily too technical for prolonged discussion. The question of the utility of microscopic analysis in the steel industries was introduced by Mr. C. H. Ridsdale, who pointed out that, valuable and interesting as many of the communications and discussions had been, they had been so chiefly either from a general or else from a purely scientific point of view. He then explained in detail how he had systematised the microscopic study of steel, and rendered it available for every-day use in a busy laboratory, where commercial objects must ever predominate, so that it might be carried on with minimum demands on time or of specially expensive appliances, or other serious cost, while it should be of such value as to really have a *raison d'être*. He also gave some of the results of his study of soft steel up to the present time. The President observed that he had given a great deal of attention to the subject of the paper, which was a very important one; and the only doubt in his mind was as to whether the method of examination adopted by Mr. Ridsdale was the best one for the purpose. In expressing that doubt he wished it to be distinctly understood that he in no way decried the labours of the author, or of the principle involved; he simply questioned one or two points of practice. M. Greiner, of Seraing, said he highly appreciated the principle of microscopical analysis, and suggested that the Institute as a body should set to work to formulate a systematic method of procedure, by means of which uniformity of results might always be obtained. Prof. Porter, of Montreal, stated that the importance of the subject under discussion was fully recognised in the United States and Canada, and he was engaged in equipping an expensive micro-laboratory in his college at Montreal.

The Wellmann expedition has been brought back to Tromso from Franz Josef's Land. It is reported that the explorers reached the 82nd parallel of north latitude. A member of the expedition named Bentzen, who wintered with one companion in a stone hut on the island of Wilzienland in intense cold, died. In February Mr. Wellmann had his foot crushed in an ice-squeeze, and is still obliged to use crutches. The expedition killed 103 walruses and eight bears. No trace of the Andrée Expedition was found. The *Capella* picked up the expedition on the 27th July, and sailed homeward on the 10th August. On the 6th inst. the *Stella Polare*, with the party of explorers, headed by the Italian Prince, the Duke of the Abruzzi, on board, was sighted in Broejens Sound 80° 20′ N. latitude. The full report will be received shortly, and with interest, as it appears some important observation have been made.

At the Zoological Gardens the new zebras deposited by the Queen are much better for their rest in roomy quarters, and thrive on the improved rations served to them. A Burchell's zebra has been born, and attracted nearly as much attention as the far rarer animals deposited by her Majesty. This species does well at the Gardens; and, with so magnificent a collection of wild asses—self-coloured and striped—as there is at the Zoo, it is suggested that they should be utilised for experiments on similar lines to those carried out by Prof. Cossar Ewart at Penycuik, for these would be sure to throw considerable light on questions of hybridisation, reversion, and telegony. There is also an economic side to the question, to which the society in its early days gave some attention; nearly seventy years ago a pair of quagga mules drew one of their carts about London. A puma cub has been born in the lion house, but will not be shown for some days. Then visitors will have an opportunity of seeing how these New World cats, which are of a uniform colour when adult, are spotted and have the tails ringed in their cubhood. To the aviaries have been added, by purchase, three pink-headed ducks from India. Though nowhere common, they are most plentiful in Bengal. A pair were imported in 1874, and secured for the Gardens, but they did not breed. In 1887, when the late Mr. Jamrach secured several pairs, he found ready purchasers, chiefly on the Continent, at from £40 to £60 a pair. They should make fine birds for ornamental water, the clear rose pink of the head and neck showing up well against the chocolate and brown of the back. Since 1874 only one other specimen has been exhibited in the Regent's Park aviaries.

In reference to the colliery explosion in South Wales, it is probable that there will be an inquiry into the conditions, which may help to elucidate the fact such explosions should not occur unless the circumstances are exceptional. It is doubtful whether it is ever really safe to work a mine with naked lights.

According to a news par. from New York, the movement started at Chicago to obtain a national petition to Congress to suppress copper money has reached New York. Experiments made by Chicago bacteriologists showed that there were many cases of communication of disease to children through coppers. No copper coin examined by them was free from disease germs.

Similarly from Coney Island, the news comes that the lemonade has been made of "citric acid by unscrupulous dealers," owing to the scarcity of lemons, and "there are many cases in the hospital." The reporter does not apparently suspect the ice, and he evidently does not know that citric acid is made from lemons.

A new regulation on Russian weights and measures is officially published. The Russian pound, which is fixed as the standard of weight, and declared to be equal to 409·512 grammes, a pail or vedro should hold 30lb. of distilled water at 16 2-3 (Celsius), and a garnez 8lb. of water. The unit of length is the Arshin, equal to 71·12 centimètres. The metric system is to be optional, and may be used on a par with the Russian in commerce in dealing with contracts, accounts, &c., and after mutual agreement by State and municipal authorities. Private persons are, however, to be under no compulsion to use the metrical system when dealing with the above-named authorities. Apparently there are some signs of progress in Russia.

The latest remarkable news from America is sent by the New York correspondent of the *Morning Leader*, who writes:—"A powerful electro-magnet, the invention of Dr. Haab, a German professor, recently added to the equipment of the Manhattan Eye and Ear Hospital, was tested with great success a few days ago, when an operation was performed on a patient, who was brought to that institution almost blinded from a sliver of steel which had been hurled into his eye from a rapidly-revolving lathe. The steel had cut almost through the entire eye into the posterior chamber in the vitreous fluid, where it was impossible to reach it with an instrument. The consequence of its remaining, however, would result in blindness possibly of both eyes. The giant magnet, which is so powerful that it will seize a large bunch of keys thrown at it with a vice-like grip (*sic*) was brought on the scene. The patient was moved gradually toward the magnet, and as the eye came nearer and nearer it was drawn far out from the socket. The pain was almost unbearable, but as the piece of steel came slowly through the opening it had made going in, and flew like a flash to the magnet, the socket fell back in its place. The eye would have had to come out entirely were it not for the magnet, and it is believed that the patient will soon recover. The magnet is shaped at each end like a torpedo; it is 22in. long and 14in. in diameter, and is strong enough to draw a nail from a board."

Further and most decisive trials of the submarine boat *Holland* took place in Picnic Bay, New York, last week. She was submerged when proceeding at a speed of 7½ knots, and disappeared in less than five seconds. She remained submerged on an even keel throughout the distance of a mile, and she discharged a dummy torpedo without any disturbance of the surface water.

The important scheme for making a canal between Marseilles and the Rhone is being pushed forward with much energy, the promoters having succeeded in obtaining a promise of a large Government subsidy. The course of the canal will be from the northern end of Marseilles Harbour, through the mountain chain of Rove by means of a tunnel four and a half miles long to Lake Solmon. Thence, by way of Berre and Martigne, it would effect a junction with the existing Canal Maritime, the course of which would be followed as far as Port de Bouc, where a short connecting water-way would open into the Arles Canal. From that point to the Rhone is only a short distance.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

REPORT OF THE PARIS OBSERVATORY FOR 1898—THE HUYGHENIAN EYEPIECE—REDUCING INTENSITY OF SUNLIGHT—OPTICAL DEALERS—TRADITIONS OF THE DELUGE—STELLAR PHOTOMETER—"THE STORY OF OUR PLANET"—INCLINATION OF THE PLANETARY POLES, &c.—ABSOLUTE TEMPERATURE.

[42712.]—THE Annual Report of the Director of the Paris Observatory for the year 1898 scarcely yields to any of its predecessors in interest, showing as it does how M. Lœwy, its gifted head, has contrived to overcome difficulties before which many men might well have stood helpless. One of the principal works in which he has been engaged is in a successful attempt to insure and preserve the stability of the meridian instruments, a work the importance of which it would be difficult to over-estimate. Beginning with the Meridian Circle in the Garden, whose piers were originally erected on made earth, they are now carried down on to a solid bed of concrete, some 40ft. thick, which rests upon the limestone rock beneath. Furthermore, the circle was read by six microscopes affixed to the east pier, with which anomalous results were obtained. Now, a second series of six microscopes has been attached to the west pier, so that both circles are read, and the improvement is notable, *inter alia*, in the determination of the Nadir point. The revolving hut of the small equatorial coudé has been covered with cork, thus protecting the instrument from variations of temperature. But M. Lœwy has been met with a new and unexpected difficulty, and one which, it seems to me, must perforce involve the removal of the observatory from the familiar site which it has occupied for the last 230 years. As all visitors to Paris know, the extensive grounds to the south of the observatory face on the Rue Cassini, and although the vibration of the tram running down the Rue Denfert-Rocherau close by sometimes renders the use of the mercury collimator difficult or impossible, yet until last year the east part of the Rue Cassini, adjoining the garden of the Observatory, was always closed to traffic. But in Paris, as in London, nothing is sacred to the builder, and an important building has been erected in that part closest to the meridian instruments, and the City of Paris has entered into an agreement with Madame André, its proprietor, to open the street for carriages for its entire length. The Minister of Education has, at the instance of the council and directors of the Observatory, tried in vain to get this latter order cancelled. The utmost he has succeeded in obtaining is a promise that the pavement shall be asphalte and the roadway wood. The effect of this upon the precision of meridian observations must be only too apparent. Turning from this to the actual work achieved, the section of the photographic map of the Heavens confided to the Observatory may be considered as complete, a very few lacunæ, caused by the bad weather of certain seasons of the year, alone remaining to be filled. Hereafter, the principal object of photographic work will be the obtaining of the image of stars up to the 14th magnitude. The splendid atlas of the moon of MM. Lœwy and Puiseux progresses apace, and one of their exquisite clichées of our satellite when between 20 and 21 days old forms a frontispiece to the present Report. Some interesting

results, pointing to the mode of origin of certain familiar lunar formations, have been deduced by the authors from their photographs. M. Bigourdan has used the western equatorial for the observation of the physical and chemical structure of nebulæ, while M. Hamy, on the nights when the great equatorial coudé was not employed in photographing the moon, has employed it in the determination of the diameters of small stars by the method of interference. He has thus successfully measured the diameters of Vesta and of Jupiter's satellites. That of Vesta he finds to be about 0·4″. Of the general meridian work, the reduction of the stellar photographs, &c., &c., it is needless to speak at length. Anyone and everyone interested will find ample evidence of the energy and its concomitant success, alike of the director and his staff in the perusal of the "Rapport" itself.

Among much that is interesting in the August number of the *Journal* of the British Astronomical Association, I would call attention to a paper by Mr. E. M. Nelson on the Huyghenian Eyepiece, which will well repay perusal. The particular form of it devised by Mr. Nelson has a field of 33°, which is ample for all practical purposes; and further possesses an advantage which will be appreciated by all observers—viz., that the annoying secondary image, known as a "ghost," which is visible in some eyepieces, is wholly eliminated.

In connection with what Mr. Ellison says (in letter 42662) on p. 576, of Vol. LXIX., concerning the reduction of the intensity of the sun's light and heat in the telescope, I may mention that more years ago than I care to count, the late Andrew Ross fitted some of my eyepieces with tubes which carried coloured glasses within the solar focus of the instrument, and so intercepted the rays from the objective before they arrived at their point of highest concentration. The late Mr. C. L. Prince, F.R.A.S., produced the same effect by the aid of a piece of smoked glass placed in the diaphragm of an eyepiece. The first of these devices is that, as he will see, which your correspondent has reinvented. That of Mr. Prince pretty quickly got unpleasantly hot.

"Hear Both Sides" (letter 42664, p. 577, Vol. LXIX.) quotes more than one case in which it seems to me the aggrieved party had a legal remedy. It has been decided in the High Court of Justice that: If a tradesman sell an article for a particular use or purpose, he thereby impliedly warrants that it is fit for that particular use and purpose (vide "Jones v. Bright," "Brown v. Edgington," &c.), and can be made responsible in damages. It seems, then, to me that to take a single instance, in that case of the £50 6in. achromatic, so far from the purchaser having "no redress," he could have sued the vendor, and certainly got a verdict against him.

I am at a loss to imagine upon what grounds Mr. Rouse (letter 42665, Vol. LXIX., p. 577) asserts that *I* "incline to the belief that this tradition (of the Flood), which seems otherwise to have spread all over the globe, had originated in an extraordinary overflow of the Nile." I stated, in letter 42529, on p. 442 of that volume, that Sir George Airy expressed that opinion, but most certainly not that I held it. My own idea is that the legend of the Deluge had its origin in the finding of fossil shells in mountains at a great altitude above the sea-level by people whose knowledge of geology was, *ex necessitate*, nil. That great and devastating local inundations may have given rise in the regions in which they occurred to legends of a Flood originally, is quite possible; but the belief in the universality of such a cataclysm would be most materially strengthened by the finding, as I have just said, of shells in rocks elevated many thousand of feet above the sea. Mr. Rouse's peroration is really delightful. The derivation of Cucumber from King Jeremiah seems almost a poverty-stricken conception beside it.

The most simple photometer that I can recommend to "X Y Z" (query 96432, Vol. LXIX. p. 584) would take the form of a series of diaphragms to fit over his object-glass. The first thing is to procure one of exactly 1in. in aperture, and determine from Argelander the smallest of his magnitudes *just* discernible on a clear moonless night with this. Call this L, or the limit of vision for 1in., then the limit l for any other aperture will be $l = L + 5 \times \log.$ aperture. This is known as Pogson's formula. Now suppose that "X Y Z" finds, as he probably will, that the 9th magnitude is the *minimum visibile* with his inch diaphragm, what is the magnitude of a star he can just perceive with an aperture of 0·2in.? Here we have $l = 9 + 5 \log. 0{\cdot}2$, and as $\log. 2 = \bar{1}{\cdot}301030$, five times this is $\bar{4}{\cdot}505150$. Finally—

$$\begin{array}{r} 9 \\ \bar{4}{\cdot}50 \\ \hline 5{\cdot}50 \end{array}$$

gives us 5·50 as the smallest star visible. Or, what is the limit of vision for 3in. of aperture? Here we have log. 3 = 0·47712, and this × 5 = 2·38560. If to this, then, we add 9, we get 11·39 as the *minimum visibile* with the aperture specified. Another form of photometer consists of a graduated wedge of coloured glass sliding before the eyepiece. The value of different parts of this must be obtained by comparison with some such catalogue as that of Pickering's Harvard Photometry. Wesley and Son, 28, Essex-street, Strand, London, would be the people to obtain this from.

I recommended Prof. Bonney's "Story of Our Planet" to "Glatton" (in letter 42659, p. 576 of your last volume) as a most interesting and readable book at a moderate price; but as this seems to have raised the ire of "E. L. G." (letter 42694, p. 15), I would say that Lyell's "Students' Elements of Geology," Geikie's "Textbook of Geology"; or, in short, any standard work on the subject will answer just as well.

The following data, derived from Young's "General Astronomy," will probably answer the purpose of "J. R. J." (query 96467, p. 22)—

Planet.	Inclination of Orbit to Ecliptic.			Inclination of Planet's Equation to its Orbit.

* The planes of the five inner orbits sensibly correspond with the plane of the Ring.

I must absolutely refuse to touch the monkey puzzle, the discussion whereon is the veriest logomachy.

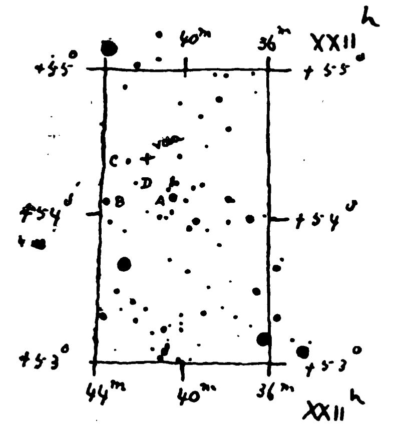
If, as is presumably the case, by "absolute temperature" "B. L." (query 96476, p. 22) means the absolute zero of temperature, this was found by Joule and Lord Kelvin to be −461° Fahr. (Olszewski has actually measured −373° Fahr.!) There is no satisfactory determination of the temperature of space, for temperature can only exist where there is matter. The boiling point of liquid hydrogen is that at which it passes from the vaporous to the liquid form, or vice versâ.

A Fellow of the Royal Astronomical Society.

THE VARIABLE STAR ES-BIRM. 735—A NEW NEBULA—THE CLUSTER H. VI. 30 CASSIOPEIÆ, AND A POSSIBLE VARIABLE STAR.

[42713.]—(1) Es-Birm. 735, R.A. 22h. 43·7m., N. Decl. + 54° 38′ (1900). This star was found in sweeping on Oct. 20, 1887, and a circle reading led me to identify it with B.D. + 54° 2865. It was only in 1893 that I found it was really to be identified with B.D. + 54° 2863, whose magnitude in Argelander is 9·5. As it was a whole magnitude; brighter, suspicion of variability was at once aroused. The telescope being employed in sweeping for stars of type III. and IV. makes it impossible to follow up the variable stars accidentally detected, but occasional observations are made of suspected variables when the telescope is in use in that part of the sky. The following are all the observations I have of this star:—1887, Oct. 20, 8·5; Dec. 4, 8·2; Dec. 7, 8·5; mean = 8·4. 1893, Oct. 8, 8·5; Oct. 11, 16, Dec. 1, 1894 Jan. 9, 8.3; mean = 8·3. 1894, Sept. 10, 7·9; Oct. 21, 7·4; Oct. 29, 8·0; Nov. 29, 7·6; mean = 7·7.

These results are interesting, as showing that the variation is very slow. In 1887, 1893 the variation was inappreciable; in 1894 there seems to have been fluctuation, and the mean shows the star considerably brighter. It will be noticed that it has never been seen so faint as given by Argelander. Can the star have slowly brightened since his time? The variation has been confirmed by Parkhurst and Backhouse, and it would be of interest to see their observations. I inclose a tracing from Argelander, showing the position of the star. The magnitudes



Es-Birm 735

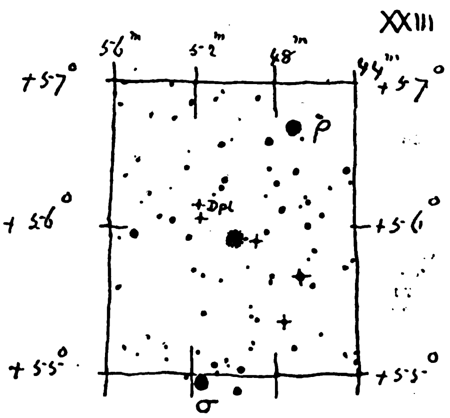
of the stars A, B, C, D are respectively 7·1, 8·0, 8·5, 9·0. The four large stars are in Argelander all 6·0 mag. For those who have not equatorials, it may be helpful to state that a line from Alpha Lacertæ to 9 Lacertæ projected to twice the distance between these stars will find the 6-mag. star south of the variable. The other bright star N is B.A.C. 7961, and its magnitude 5·4 in the Harvard Photometry.

(2) In the sweeps with the 17¼in. it is customary to note any nebulæ that are come across, and on Aug. 13 I found a large diffused nebulosity not a difficult object, the centre of which is—

R.A. 21h. 47m. 54s., N.Dec. 46° 34′ (1855).

It is fairly circular, and fades away on all sides, and some 10′ in diameter. Much to my astonishment I found next morning that it is hitherto unrecorded. I should think it is not more difficult than the Merope nebula, but like it, it requires a low power.

(3) Between ρ and σ Cassiopeiæ lies the cluster H. VI. 30, R.A. 23h. 52m., Decl. N. 56° 9′. Celestial



Cluster H. VI. 30 Cassiopeia
Coloured stars marked +

Objects, p. 75. With a low power a lovely object, and with a higher one quite resolved stars 10 to 14 mag. on Aug. 13. I examined it for red stars. P is an orange red (Es. 1249), mag. 8·7, showing a well-developed III. type spectrum. F is a 9·0 mag. orange red, with apparently similar spectrum. About 6′ N. of this star a pair caught my attention, the *comes* being a dull-looking object. With a higher power it turned out to be deep red. The neighbouring star prevented any satisfactory observation with the spectroscope. I estimated the pair as—

P = 230° ± D. 15″ ± mag. 9·3, 9·8.

The star is B.D. 56° 3126 R.A. 23h. 51m. 45·8s.,

Decl. + 56° 9·5′. Now on turning to the Hels.-Gotha zones, I find this star is mentioned as a double in zone 109 (1870, Oct. 12), mag. 9·2 "dupl. 16″ sq. *comes* 9·5." It would thus appear that the preceding or red star was then the brightest. The pair is very like U Cygni, and the red will probably turn out to be a variable. A tracing from Argelander showing the cluster, and ρ and σ Cassiopeiæ, with the coloured stars marked, may be helpful.

Tow Law, Co. Durham, Aug. 15.

THE PERSEIDS, 1899.—II.

[42714.]—In continuation of my former letter (42690, p. 14), I subjoin an account of watches recently kept for meteors. These were as follows:—Aug. 11, 10h. 5m. to 11h. 13m. (16 meteors, including one seen during a momentary glance at the sky at 9h. 55m.); Aug. 12, 10h. 25m. to 12h. 15m. (30 meteors); Aug. 14, 10h. 50m. to 13h. 0m. (24 meteors). Total, 5h. 8m. (70 meteors). All were determined by clouds. The hourly rates of meteors during the period of observation on the several nights were 14, 16, and 11 respectively.

Another meteor as bright as Jupiter was observed by my brother at 10h. 35m. on Aug. 14. It travelled swiftly from 2° + 55° to 357½° + 10°, and left a streak.

The times, &c., of the 70 meteors are set out in the annexed table.

Date.		Radiants.	Meteors.
F.	Aug. 11	4° + 50°	(93, 99, 101, 102).
G.	,, 11	45 + 57	(88-90, 92, 95, 96, 98, 100).
H.	,, 12	0½ + 54	(103, 114, 126, 127).
I.	,, 12	48 + 58	(104, 106-8, 111, 113, 116-118, 120, 122-124, 129, 131).
J.	,, 14	5 + 52½	(137, 140, 145, 147, 155).
K.	,, 14	50 + 58	(135, 144, 146, 148, 153).
L.	,, 14	343½ + 52½	(136, 138, 139, 141).

MAGNITUDES.

In my letter above referred to in last week's issue, for "4" as the magnitude of meteor of No. 11, read "♃."

Walter. E. Besley.

The Chase, Clapham Common, Aug 19.

OBSERVATORY LIGHT.

[42715.]—Has anyone devised a really satisfactory light for the amateur observer yet? After trying many different lamps, I have now a 2½c.p. 8-volt incandescent lamp, worked by a small four-cell Pitkin accumulator, with variable resistance to adjust light for micrometer illumination, &c. The lampholder has flexible wire attached, and finding eyepieces, reading circles, looking at star maps, &c., are all easily performed. The trouble lies with the accumulator. No charging station within easy reach, heavy to carry, constant loss by local action when not in use, and life of plates not interminable. That I have put up with these objections, however, for two or three years speaks well for the battery and general convenience and cleanliness of the light when once obtained. Still, I should much like to hear whether Mr. Bottone or some other kind friend can improve upon it.

Would it be practically possible to drive a small dynamo by a falling weight? I mean something that could be wound up by hand with a windlass, and, if allowed to fall continuously, say 6ft. or 8ft., keep a small lamp going for perhaps a couple of hours. Of course, the light would not often be wanted for many minutes consecutively, and no doubt the weight could be controlled by some form of brake. Would such a plan be feasible?—and if so, what would be the most suitable design for the driving apparatus, to be erected outside observatory? I understand the armature of a small dynamo requires to be driven at between 2,000 and 3,000 revolutions per minute? If this could be accomplished, it seems to me that the plan would have the double merit of durability and that complete independence of gas and electric companies needful in out-of-the-way places.

F. D. C. Baly.

SOLAR EYE-SHADES FOR TELESCOPES.

[42716.]—I have never tried placing a coloured-glass shade between the eyepiece and the object-glass, so cannot speak from experience; but it seems to me that unless the quality of the glass of the coloured shade was of the finest, it would seriously affect the definition, as any imperfection in the glass, and consequent distortion of the image, would be magnified when in that position; though I see that Mr. Ryle (letter 42688) says that he has found the definition under these conditions to be excellent.

I have used coloured eye-shades for direct vision with both a 2¼in. and a 5in. refractor; but with neither of them were the shades of any use. With the 2¼in. fusion took place after three or four short observations (in mid-winter); with the 5in. they fused almost instantly, and in one case, with a low power (75), the glass was shivered the moment I turned the instrument on to the sun; fortunately before I had time to apply my eye to the eyepiece. Since this accident I never attempt to observe sun by direct vision with the 5in., but always use an ordinary stellar prism, which, with the shades that were supplied for direct vision, gives most satisfactory and most comfortable views, much superior to those given by Sir Howard Grubb's "combined polarising and Dawe's solar eyepiece." It is only fair, however, to say that the inferiority of this latter eyepiece is due to its coloured shade not being deep enough, and too yellow. Slate-blue I find by far the most comfortable shades to use.

N. Maclachlan.

Rontenburn, Largs, N.B., Aug. 20.

TO "H."—DIVIDING POWER OF AN OLD GREGORIAN.

[42717.]—My humble appeal in letter 42576 has failed to elicit any fellow-sufferer's London experiences with small telescopes, but had the good fortune to be noticed by so eminent a contributor to your valuable journal as "H.," in his interesting letter 42668. This encourages me to give some further experiences with my old 3¾in. Gregorian, hoping that they may be of interest, at least from an historical point of view, in the matter of instrument-making.

Since writing the above-mentioned letter some tolerably favourable observing nights occurred in West London. On one of these—July 19, about 10 o'clock—I succeeded, to my great pleasure, in unmistakably dividing Epsilon Böotis (distance 2·6″, according to Webb), with my highest power—about 180 or 200. It was not easy; but required the utmost strain and perseverance in seeing; yet once caught, I succeeded more easily in seeing it again. The appearance was that of a faint point of light glimmering close upon, but clearly separate from, the principal star, being, however, immersed in the latter's interference rings. This dim, ghostly little light seemed an infinite distance behind the bright principal, thus presenting a very weird and fascin-

ating picture. But no colours were caught, nor were the discs as clean and round as I saw those of γ Leonis, as mentioned in my letter No. 42576.

I guarded myself against possible deception, first by moving eyepiece and head without any effect on P.A.; secondly, by frequent comparisons with α Coronæ, which showed no ghostly points of light whatever; and thirdly, by estimating the P.A. correctly to within about 20 degrees, without any previous knowledge of it.

This may be no special feat for a 3¾in. Gregorian, as the late Prebendary Webb divided ε Boötis "perfectly" with 2¼in. achromatic; but, considering that my eyes are quite untrained, and that the speculum doubtlessly has an imperfect spherical figure, not to speak of beginning signs of old age, it bears good testimony, I think, to the skill of its maker, and proves that even old Gregorians need not be quite worthless. Perhaps "H." can kindly furnish nearer data of its origin if I mention the inscription on its back-plate. It is, "James Short, London—$\frac{11}{503}$ = 18." The small specula have no adjustment for centring, and the focussing screw is carried right along outside the tube. Also terrestrially it performs well. At the seaside it showed distinctly, with p. 45 or 50, the whole network of ropes on vessels at least 12 to 14 miles away, judging by the known distance of a lightship.

C. H. Stielow.

GREGORIANS, &c.

[42718.]—I SHOULD indeed be wanting in courtesy if I did not thank and *heartily* thank "H." for his kind expressions in letter 42689; but at my age and with my many ailings I can but recognise that the time must soon come when the correspondent through 70 vols. of the "E.M." will correspond no more. Till then, however, I shall do what little lies in my power to help others as "H." and others have so often helped me.

One thing more. I can truly say that, though (as "H." remarks) we may have occasionally differed, I have derived more information from "H.'s" masterly letters than from all the textbooks I ever read, and their number is not small.

Apologising for this long "personal" preface, I will take up the several points in his letter. I do not think "H." and I really differ about the relative aberration in Gregorians and Cassegrains. I said in my former letter (p. 557) "The total amount of aberration *to be dealt with*, &c." If the mirrors were theoretically perfect the aberration would *have been*, and not "*to be*," dealt with, and both telescopes would be (apart from "Schaeberle error") equally perfect. If, however, the mirrors are *not* "theoretically perfect" (and they never are, for even Short had to "match" them by trial), I certainly think the remaining aberration would be more in the Gregorian than in the Cassegrain, assuming the actual amount of error in the mirrors to be the same in both.

In this connection I confess to having doubts as to the accuracy of figure of modern Newtonian mirrors whose performance is said to be "improved" by using a Barlow lens! "Ell Hay's" comparison between the Gregorian and Newtonian form of his telescope is interesting, but would have been far more so if he had told us how he managed to secure a correct curve for his small mirror, or whether he found it necessary to make several, and select the best by trial.

As regards a comparison with *old* Gregorians, the latter would have had a focal length of only two-thirds that of this "Newtonian-Gregorian."

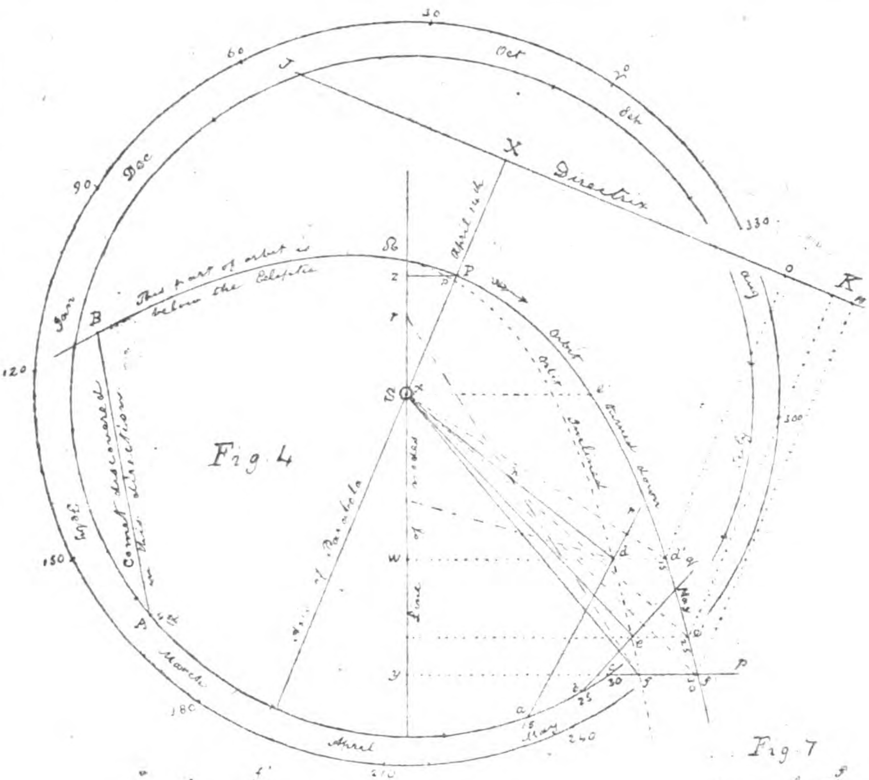
In using the term "aplanatic," I did so with some hesitation; but I thought "H." would understand thereby a secondary image lying wholly in one plane, of which the straight line V L in his diagram represented a section. From his original diagram of a Gregorian, it is evident "H." is as handy with drawing instruments as he is with his (mental) calculating machine. I wish he would draw a large mirror of short focus (say three times its diameter, as used by Kitchiner), and a corresponding small mirror, using any curves (conic sections) that he pleases, and assuming a *straight* line (as V L) to represent the secondary image; then, selecting a few points in V L, let him draw the rays, proceeding backwards till he obtains the directions of the incident rays; then, if these are found to be parallel to the axis, it proves that the curves required *are* conic sections, and vice versâ. I think they will *not* be parallel to the axis.

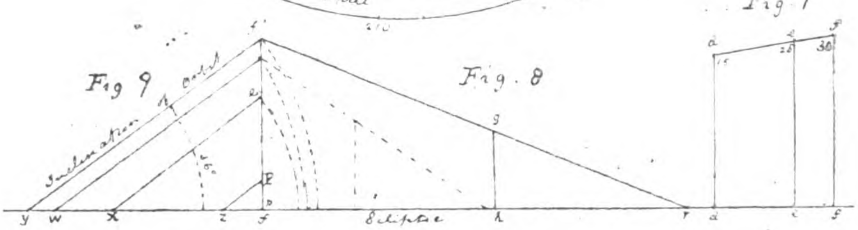
I quite agree with "Balolo's" remarks as to "H.'s" ingenious method of finding size of eye-hole and its correct position.

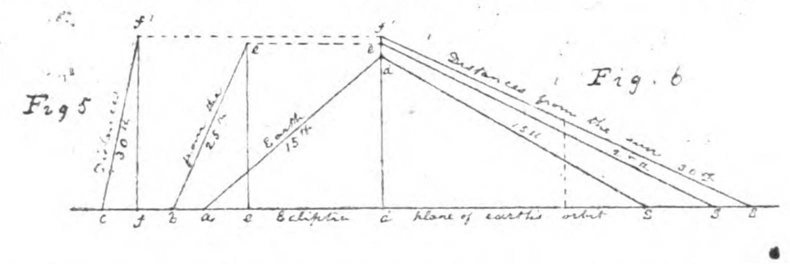
A. S. L.

ORBIT OF SWIFT'S COMET BY PROJECTION.

[42719.]—THE accompanying diagram will further illustrate the method for finding the orbit of a comet by projection, described in letters (42555, p. 464) and (42581, p. 488). In those letters the orbits found were for fictitious comets for the purpose of clearness in description. The present illustration of the orbit of Swift's comet was projected by the method described in the above letters, the figuring and lettering being the same as in the previous diagrams, as near as may be, so that description can be used in this case.







The projection of this orbit was not undertaken with a view to its publication, so no special care was taken with that end in view; but I have thought since the above letters were inserted that it might be desirable to present the solution of a real orbit, and so the original drawing has been reduced for that purpose, and sent to our obliging Editor.

It was not until May 15th that any first observation of position of the comet was obtained, and the other positions used were at intervals from that date, of ten and five days respectively, my last observation being on the 30th; but my positions having been obtained by home-made apparatus, can only be roughly approximate it would be a great convenience if observed positions were published.

The following were the positions used in finding the orbit:—

Time.	Longitude.	Latitude.
May 15	4·7°	41·25
,, 25	350·5	66 6
,, 30	309 0	79·35

And the elements of the orbit came out. Time, April 14·4th:—

Longitude of Perihelion	11·0°
Longitude of ascending node	33·6
Inclination of orbit	36·0
Perihelion distance	·376

Motion retrograde.

Do not know how these elements compare with those given by professionals, as I have not seen any other list of elements for this comet.

The general observer may find it interesting to notice that at the time of discovery the comet and earth were moving from one another until near the time of perihelion passage; after that event they were approaching one another until the end of May, when the comet was distant from the earth a trifle more than half the earth's distance from the sun; it will also be seen that about the beginning of April the comet was in the direction of, and beyond, the sun, so that when at its brightest it was impossible to see it from the earth.

With reference to suggestions in letter 42582, p. 490, upon this subject—(1) the scale, Fig. 2, was not intended to be used to check the correctness of the diagram. (2) When working by trial and error, it would be inconvenient to have to find the velocity for each different distance between each trial; but when the points are found by the scale, the work can then be checked, and, if needful, corrected by calculation. This remark will also apply to other parts of the problem.

Wimbish, August 12. J. Lane.

THE DELUGE AND ITS BLESSINGS.

[42720.]—IT is very astonishing that nobody can be induced to examine Nouri's diluvial relics. "Do we advance much?" asks "J. W." Seven years after the discovery, nobody can explore the few miles.

The Rev. Samuel Graham Wilson, M.A., fifteen years a missionary in Persia, writes a book on "Persian Life and Customs," living at Tabriz, about 100 miles from the alleged ruins. He says, "In 1883, the *Levant Herald* published a detailed account of an alleged discovery of the Ark on Mount Ararat. In 1893, Dr. Honri, a Chaldean archdeacon, claimed to have seen the ancient 'house boat.' It would be interesting to know what it is that has apparently deceived these worthy, and no doubt veracious, chroniclers?"

What has *deceived* them? Why on earth must they have been deceived at all? In Heaven's name, what is a missionary for, if not to investigate such discoveries?

Mr. Dormer says, "I do not mention why extinct animals alive in 3102 B.C. were not preserved in the

Ark? Where is the promise that all then living were to be preserved? God promised to bring to Noah those that were to save seed alive; not all that were living. We may thank Him we have no woolly rhinoceroses, mastodons, and especially no salve-toothed tigers. A great destruction of flesh was threatened because the earth was filled with violence through them. Partly by human violence, but also that of other flesh that had corrupted its way. We may take it as pretty certain that the Deluge was necessary to preserve our species even another century. Without it, there may have been children to Shem and Japhet, but hardly grand-children. E. L. Garbett.

THE DELUGE.

[42721.]—May I venture to inquire what would happen if the South magnetic Pole was moved, say, a thousand miles or so nearer north. I have an idea that before the Flood the South Pole did occupy such a place, and that the movement into its present position cause the Flood, by throwing the seas upon the land. The long-promised millennium may be a restoration of the South Pole to its former position, and movements of the magnetic Pole may have caused the return of the shadow on Ahaz's dial.

I believe my idea to be perfectly original. But it may be stale. Little Bookham.

[42722.]—I hope before the propounders of the Mount Ararat in Armenia and the cometary theory of the deluge retire that you will permit me to state, as a student of all theories, that I think the most reasonable and pleasing explanation of this Biblical mystery is that of the Allegorists. Fraser, in his "Golden Bough," and Prof. Max Müller, in his "Science of Religion," touch upon this subject, and show clearly that as an allegory it is undoubtedly founded upon a universal system of mythology and the religious system of allegorising astronomical facts and natural phenomena, which is found as the common stock property of all religions—Pagan, Jewish, and Christian.

The recent hot spell of weather in London has, however, somewhat shaken my faith, and I have panted for the snow-clad summit of Ararat, where, in the company of the genial "E. L. G.," one might camp out, and boil their pot with some of the remains of the Ark, which your correspondent assures us is to be found there.

40, Spondon-road, Tottenham. T. May.

[42723.]—The paralysis of common sense seems indissolubly connected with this subject. There has been clearly a continuity of land-life at least since the coal-measures were formed. One regrets, therefore, to see "J. W." (letter 42692) advocating universal deluges every 22,000 years. Similar opinions were prevalent in the early years of this century, and Darwin was inclined to explain the extinction of certain species of animals in South America catastrophically in consequence. But with a fuller acquaintance with facts accumulated later, he acknowledges in the "Origin" that his astonishment was groundless, and cataclysms superfluous. Has "J. W." imbibed the idea by reading some geological literature of half a century ago? J. Dormer.

[42724.]—The question of a universal deluge is one of considerable interest, though our conclusions will largely depend on the amount of trust which we place in early traditions. Mr. Garbett's theory, however, is that this Deluge took place at a different date from that usually assigned to it, and that it was caused by a comet composed of water. He seems to me to have done nothing towards proving that a great comet actually visited us at the date mentioned by him, and still less, if possible, towards proving that this or any other comet consisted of water, whether solid, fluid, or gaseous. But it would be interesting to know how he came to fix upon the date which he assigns to the Deluge. As to the geological evidence to which he appeals, I do not suppose that any geologist could fix the date of what he regards as diluvial deposits without a possible error of 1,000 years. On the other hand, the Bible, if the existing text can be relied on, gives a date differing considerably from Mr. Garbett's, and if, as that writer holds, the Book of Genesis was written as late as the time of Samuel, its authority is not thereby strengthened, especially in the matter of dates.

I hope Mr. Garbett will try his hand at solving Mr. Ellison's problem of the fly. He holds that large quantities of water may be suspended in the air without increasing the atmospheric pressure at the earth's surface. The fly would, I presume, be in the same position, as, indeed, would the largest eagle when in flight. It reminds me of the old question why a live fish did not add to the weight of the water, while a dead fish did so. W. H. S. Monck.

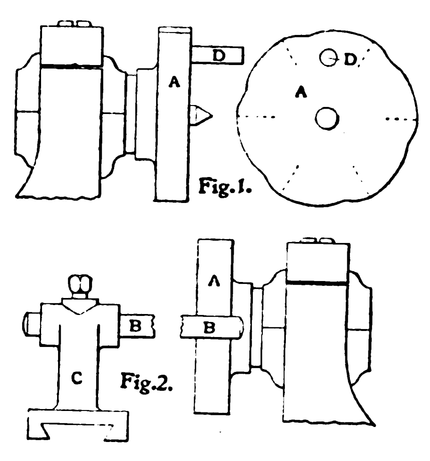
"PROF. BONNEY'S STORY."

[42725.]—I have received a copy of your paper in which a Mr. E. L. Garbett (p. 15) is making free with my name. He asserts, if I understand him aright, that I get "£1,000 a year indisputably" for teaching on Sundays a doctrine about the Flood, or, if he likes, maintaining certain views on theological questions which are not generally held by scientific men. So far is this statement about my income from being indisputable, that I beg leave to inform him it is grossly false. T. G. Bonney.

[42726.]—Your correspondent, E. L. Garbett, evidently knows nothing of Prof. Bonney. Had he been a listener at Great St. Mary's Church one memorable Sunday in the late seventies, he could never have made such a blunder as to allege that the learned gentleman's Sunday story differed from his story of any other day. One thing Bonney never preached on Sunday or any other day of the week, and that is E. L. Garbett's story of our planet. C. P.

BACKING OFF CUTTERS.

[42727.]—The following note by Mr. C. H. Whipple, of Chicago, which I found in the *American Machinist*, may be of use to your readers. He says:—We back off our cutter in a simple way. We have a face-plate, A, which on its edges is a



cam with as many teeth as the cutter, and with the proper amount of rise and fall for the clearance. The casting C, Fig. 2, is fitted to the carriage at the back of the lathe, and can be set at any point on the carriage cross slide. The bar B is of tool steel, hardened, which will draw the cross-slide forward as every tooth in the cam passes, and a suitable spring can be applied, or weights, to draw it back, or rather to keep the bar B always in contact with the cam A. This device is applied to a Pratt and Whitney lathe, with a rise and fall rest, which allows of the cross-slide being moved back and forth. The arbor with the cutter is driven by a straight-tail dog and a driver pin on the face of the cam. The dog must, of course, be tied to the driver-pin, to prevent its getting away when the tool finishes its work on each tooth.

Cleveland, O. J. M.

WHO MADE THE SCREW PROPELLER A SUCCESS?

[42728.]—Having my attention called to a letter in your journal of July 28 (42627, page 534), in reference to "Who Made the Screw Propeller a Success?" wherein it states that experiments had been carried on by "Dowson and Pilgrim, and that both had unsuccessfully experimented with the screw," as regards screw propulsion, I cannot allow it to go before the world at large without contradiction. Being the son of the Thomas Pilgrim referred to, I may say, without any fear of contradiction, it was through his engineering abilities and indomitable perseverence, after he had joined Francis Pettit Smith (who had conceived the idea in 1834) in 1836, in the uphill fight to produce a method of propelling vessels other than by paddles. They both at that time had no knowledge whatever that any other people had been trying the same method of propulsion. Smith has often told me that if it had not been for my father's great perseverance, he would have given up the attempt. In 1836 they converted a canal-boat on the Grand Junction Canal at Paddington, which was a success. The screw at first was two entire turns of a single thread, and soon after reduced to one turn. She was the first vessel, other than models, that was propelled by a screw, and from that vessel has sprung all the screw vessels afloat at the present day. Therefore how can "Justice," in any fairness, say that my father, as an engineer, failed in the attempt to perfect the screw as a propeller for ship propulsion?

"Justice," again, says at that stage of failure Henry Wimshurst obtained permission to repair and test the capabilities of that converted canal-boat, after she had gone through her successful trials, which is erroneous, as he had nothing whatever to do with her or her method of propulsion. And again, in the same paragraph, one would imagine that Wimshurst was the ruling genius in the construction of the *Archimedes*. "Justice" must mean the parlour business at his bankers had reference to the *Novelty*, not to the *Archimedes*. It is true he built her from designs handed to him by Smith's Screw Propeller Company; that was his only share in her construction. Although I am fully aware he wanted to claim all the credit, he had nothing to do with the *Archimedes* after he had finished building her, and as to his advice in regard to experiments with her were *nil*. They rested entirely with Smith and my father. Early in 1839 the vessel went to sea with a screw of one turn, and before the year was over the one turn of a single thread was altered to one-half turn of a double thread, at my father's proposition (which was three or four years before Wimshurst built the *Novelty*). Therefore, how could he have been the introducer of the shorter length of aperture in the deadwood of the run of the ship for the propeller. The *Archimedes* in 1839 and 1840 went to all the principal ports of Great Britain and the Continent with well-known success. In 1841 she went to Bristol to experiment for the best form and length of screw for the *Great Britain*, building there by the Great Western Steam Ship Company, which had been laid down as a paddle ship, and when that company knew of the success of the *Archimedes*, they determined to alter her for the screw. The experiments were carried out by my father, who advised the shortening of the screw, and the various pitches and number of threads, and the result was, after a series of trials, that one-sixth of a turn of a double thread was the best, though with a triple thread there was less vibration. The screw at the present day remains the same with very trivial difference. All this took place before Wimshurst had built the *Novelty*; therefore, how can it possibly be said it was by him that the screw was shortened and perfected? Justice is a virtue; therefore let it fall on those to whom it is due.

In regard to the portrait of Wimshurst with his hand on the model of the stern of a screw vessel, in the Patent Office Museum, South Kensington, that was taken in 1856, to form a collection of men who had been in any way connected with the screw. Had "Justice" looked round the museum, he would have noticed an oil painting of Smith pointing to the offspring of his fertile brain, which was painted in the middle forties.

In conclusion, I can inform "Justice" where they failed—and that was in not reaping a competency to procure for them the comforts of life in their old age. Unlike Stephenson with the locomotive, who amassed a large fortune, they were comparatively penniless, and not a long distance from poverty; and myself, the last of the two families, is in anything but affluent circumstances. Which idea has been of most importance to the nation I most humbly say the screw. The nation's magnificent fleet, for the protection of our homes, colonies, and commerce, could not possibly have been so effective without it, or some other better method of propulsion; and in justice to the two men who wrought out the screw to a practical result for the benefit of the nation, it is a disgrace to that nation that those men were so ill provided for.

Apologising for troubling you on this subject, and the length of this communication.

King's Lynn, August 18. C. F. Pilgrim.

REDUCING THE INTENSITY OF LIGHT.

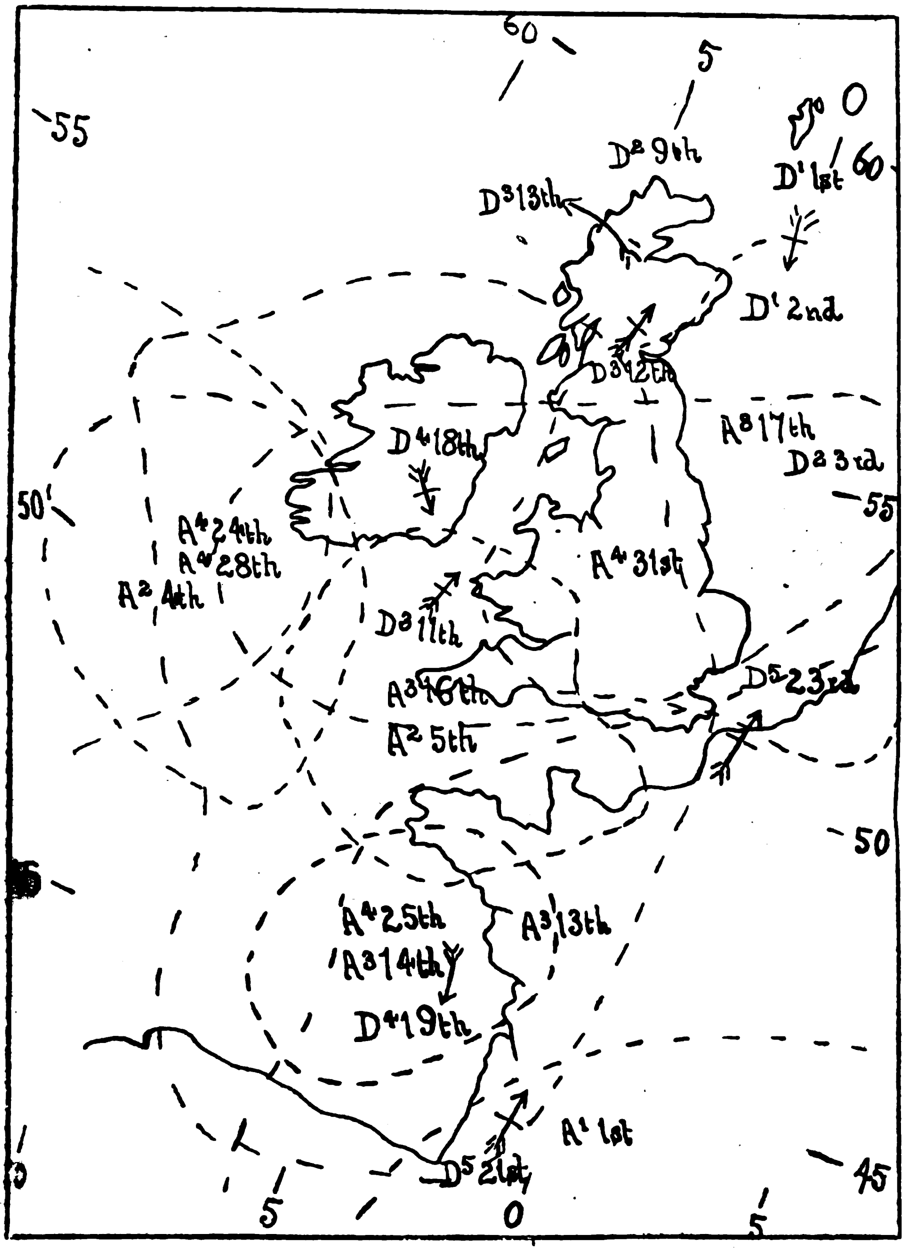
[42729.]—I have also been trying the effect of a stop, perforated with numerous medium-sized holes placed in front of the object-glass of my telescope, a 3·1in. refractor, although my eye-screens of coloured glass push into the tubes of the several eye-pieces in front of the field-lens. Even in this position they crack when the full aperture is employed. My experience coincides with that of Messrs. Ellison and Graythorp in every respect. While the light was greatly reduced, definition was ruined; but why this should be so, I cannot at present see, especially as the holes in the stop were large—⅜in. in diameter.

Perhaps "A. S. L." (who, I hope, may soon be quite recovered) or "H." would come to our assistance.

Trin. Coll., Oxon. J. M. W.

THE WEATHER OF THE BRITISH ISLES IN JULY—THE DROUGHT.

[42730.]—The writer has to commence by thanking "No. 7" for his appreciative remarks with regard to the chart and attempted elucidation of the mysteries of British weather, and the Editor for the admirable way in which it was set out. He has also to reply to a question (letter 42603) as to



whether it is not unusual for a halo and "mock-sun" to be observed with an anti-cyclone to the westward. In answer to this query, it may be said that halos and mock-suns frequently occur on the "edges" of anti-cyclones, and it may be as well to add that such phenomena are by no means an infallible sign of rain—i.e., of the approach of a depression.

Returning to the weather of July, and retaining the tabular form of "cause" and "effect," we arrive at the following conclusions:—

Date.	Cause.	Effect.
July. 1 to 3	Depression off the N.E. of Scotland. High pressure over the Iberian Peninsula.	Unsettled generally, especially in the north and east.
3 to 5	Atlantic Anti-cyclone. Low pressure over the North Sea.	Generally fair.
6 to 10	Anticyclone covering the whole of our islands.	Fine, warm weather throughout.
11 to 13	Depression to westward. High pressure area on the S.E.	Very hot, fair generally, but sudden heavy local falls of rains.
14 to 18	Anticyclone almost central.	Very fine and hot.
18 to 23	Small shallow depressions to W. and S.W., moving N.E. up the English Channel.	Heavy local thunderstorms on our S.W., S., and S.E. coasts, also in London and district on the 22nd. Generally fine.
24 to 31	Atlantic anticyclone.	Very fine and warm.

It is difficult in a month such as the one under consideration, which literally *teemed* with anti-cyclones, to preserve their individuality on the small chart at our disposal, but a careful examination will discover their centres, and the dotted lines around will show the areas. For a full explanation of the chart readers must refer to letter 42595, page 492.

Before finishing these remarks a word about the drought will not perhaps be out of place. July was the third consecutive month with a rainfall much below the average over the whole of England, though Scotland has generally benefited in the way of rainfall from depressions which have, until lately, constantly skirted our northern and north-western coasts. Should this state of affairs continue, as it did last year till mid-October, the question of water-supply will become an ever more serious matter than hitherto. **Meteor.**

TURN THE TOES OUT.

[42731.]—"S. R.," in letter 42708 (p. 18), seems to me to be so completely on a wrong line, that I am induced to make a few remarks on the point.

Perhaps I may claim to write with some authority, since I have charge of the orthopœdic department in a London hospital of repute, and make the study of orthopedics as part of orthopœdics my special professional work. (N.B.—Orthopædics, from *orthos* and *pais*—child, means childhood's symmetry; not pes, a foot merely.)

On my return from my present summer holiday, I intend to submit to our Editor a full article, with illustrations, on the main points in the mechanical structure of the human foot, and I will at present only remark that, "S. R." is quite in the right in saying that the posture in walking of the turned-out toes is taught in "drill" both in military and in dancing academies, and also that many town-dwelling educated people walk in this manner on the level, rigid surface of our pavements.

I must differ from "S. R." in his statement that "acrobats" and "ballet dancers" habitually assume the position of everted feet—the weak and unnatural position, except as a momentary action in some special movement or exercise.

The military and school drill, with the faulty, rigid nature of most of our modern boots (rigid I mean at the waist or instep of boot), are some of the most prolific causes of that result of civilisation, *flat foot*;—this I state from ample experience.

The British army will not enlist a flat-footed man; but men with good feet enter the ranks and often acquire flat-foot as a result, whilst it is only by virtue of the active habits and objection to artificial bodily postures which healthy children show, that the stupid teaching of the "dancing academies" fails to produce more cases of flat-foot than we see.

Nations conquer by their brains, not by their feet; and the higher the civilisation, and the more advanced the education, the more artificial is the physical environment; bringing with it many evils in the form of the sacrifice of natural gifts and powers of the body, and the acquiring of many faulty habits in physical movements; this everted foot being one of the worst of that class of habit.

"S. R." will, perhaps, understand my reasons for thus differing from him after he has read the paper which I hope to contribute later, in the course of a fortnight or so.

Gerard Smith, M.R.C.S., &c.
8, Nottingham-place, W.

MULTIPLYING WITH THE FINGERS.

[42732.]—In the "E.M." for 4th inst. (p. 551) there is an interesting account of the invention by a Polish mathematician of a system of multiplying numbers together by certain arrangements of the fingers. There is a very lucid explanation of details; but for my present purpose it must suffice to say that the fingers of both hands are used in three ways to represent as many series of numbers—namely, 6 to 10, 11 to 15, and 16 to 20 respectively. The method of what may be called visual multiplication together of any two of the five numbers included within any one of the sethree series is made perfectly clear; but, in the absence of further information, there appears to be a radical difficulty which would prevent application of the system to the requirements of everyday arithmetic calculation. Probably I shall best make my meaning plain by asking the question. Is this finger method capable of providing for the multiplication together of numbers *which are not in the same series?* Taking a few numbers at random, for the sake of illustration, I may instance 9 by 14, 12 by 17, and 19 by 8.

C. B.

MOTOR CYCLE: INFRINGEMENT OF PATENT.

[42733.]—With reference to long bolts of cylinder, in the year 1883 I made a double-cylinder horizontal engine for a stern-wheel steamer in that way. It was for Africa, and so made to save weight in single pieces on account of land transport.

G. W. H.

[42734.]—Regarding the point raised as to the advisability of using gunmetal cylinders by letter 42710, p. 18, I am told that cast-iron cylinders automatically harden themselves by the treatment they undergo. If this is so, it is presumably owing to their exposure to a high temperature in a carbonaceous atmosphere. But will cast iron harden under these conditions? It is an interesting point. I have it on good authority that the cylinders and covers become too hard to be touched with the file.

G. E. O.

[42735.]—Owing to pressure of business, several letters on this subject have escaped my attention. My reason for putting flanges to the brake-drum is to keep the brake-band in position sideways. I do not see any objection to these flanges. Will "Faber" (42657) let me know why he dislikes them?

In reply to "Monty" (42672), I should be glad if he would put the first paragraph into plainer wording. The way it reads at present seems to me to imply that I "followed" some of his suggestions in my drawings. The only reply needed is that both drawings and M.S. for the whole of the motor were in the Editor's hands before his letter appeared,* and I never saw them again until published, which precludes the possibility of their having been altered. The next point raised is the valve in crank chamber. This is shown in Fig. 11, and described in the text. With regard to size of inlet and exhaust, the dimensions I give are in excess of gas-engine practice, and with the speed of motor not exceeding 1,800 revs. per minute, will be found of sufficient size. In any case, they do not fall below the Dion. I agree in condemning elbows. That used for the exhaust of the Dion must check the flow of burnt gases, besides getting very hot.

* That is so.—Ed.

I am obliged to "R. J. V." (42710) for so graphically pointing out the difference between the Dion contact-breaker and the one I describe. I also believe there is a direct anticipation of the "master patent" claimed for the long cylinder bolts, and will spare no trouble to find it. Perhaps if "R. J. V." will write me, c/o the Editor, we may be able to join forces. As I am in the South (London) and he in the North, it will have to be by correspondence only, unfortunately.

The Writer of the Articles.

MOTOR CYCLES.

[42736.]—WOULD the writer of the article on "Motor Cycles" give an opinion on the possibility of motor bicycles taking the place of motor tricycles? If a satisfactory motor can be produced for a bicycle such as the one by "Armand Gancan," which was illustrated in the ENGLISH MECHANIC a few weeks ago, I think they would prove as much superior to the tricycle just as the ordinary pedal-driven bicycle is to the pedal-driven tricycle. I would like to build a tricyle, but if their place is to be taken by bicycles when a satisfactory motor is produced, is it worth while building one? Could "H. H. S." inform me where full particulars, details, &c., can be had of the motor bicycle illustrated in the "E.M." of June 30.

Glasgow. J. W.

THE FUTURE OF AERIAL LOCOMOTION.

[42737.]—I so fully endorse our Editor's remarks on p. 16, Aug. 18, that I have been disinclined to write again on the subject of mechanical flight until something effective is really accomplished. Mere correspondence without facts calls forth obnoxious criticisms from unknown persons who have done nothing in the way of any definite experiments.

I was one of the promoters of the Aëronautical Society of Great Britain, inaugurated on Jan. 6, 1866, and for many years served on the council. We received a number of communications, some of them of such a fantastic and grotesque character as to be beyond the pale of public notice. Some proposed complicated arrangements of levers and cords and internal movements, by which the effects of gravity were to be neutralised or inverted by creating a persistent unbalanced force which even these schemers themselves could not verify.

A few attempted to demonstrate the problem by mathematical deductions. Sheets were fitted with symbols, starting from a mere assumption, the end culminating in the position of "as you were," showing that mathematics in such cases is an artificial reasoning, that forms no substitute for the inventive brain of practical mechanics. There appears to be a lamentable ignorance of previous experiments with flying machines which have before been found to fail. If such had been studied, with the causes of failure, many abortive schemes would not have been attempted, and so have spared the loss of time and money of inventors. If Mr. Maxim, who has built the largest and most costly steam flying-machine, consisting of an immense and nearly square *flat* plane driven by screw vane, had looked up and carefully noted precedents, he could have foreseen causes for failure, as similar arrangements had been tried long before. He may have obtained a lifting effect of the whole contrivance; but what of that? For in a brief free flight the machine would have come to grief by reason of improper stability, and the first voyage of any foolhardy persons who ventured out in it would certainly be their last.

It may be asked, What right or reason have I for criticising? I first noticed the question of flight, and began to experiment on the subject in the year 1858. At the first meeting of the Aëronautical Society in January, 1866, I gave a *résumé* of these experiments, and the deductions derived therefrom. These appeared in their *Transactions*. I find them also published as an essay in book form by Messrs. Cassell and Co., of which I possess one copy, under the title of "Aërial Locomotion." I did not assume any fanciful movements or actions to explain bird flight, which I accounted for on tangible dynamic experiments and reasoning. To acquire flight with a machine constructed in imitation of a bird's mechanism is utterly impracticable, for such an arrangement can never meet with success. Flapping wings as a means of support for a flying-machine is an impossibility; like arrangements were first tried a century ago, and they have all ended in failure. The only feat of bird-flight that approaches the condition of an aërial machine is when birds soar at a level for nearly a mile at a time, with outstretched and motionless pinions. This occurs with the largest and heaviest species, such as vultures, pelicans, the albatross, &c. Yet in the face of all previous knowledge we still have proposers of machines to be supported by vibrating wings; I have stated that the lifting effect of the down-stroke of a surface is almost nil. Try at first with a lady's fan, say not surface enough, increase this till all your strength is used up in waving it up and down, still no considerable supporting effect. Do not try to imitate nature as in animal progression. If the first pioneers of locomotion, such as Murdoch or Trevithick, had done so, they would have produced a hideous multipod affair resembling a huge centipede! Whether the flap of a wing is directly downward, figure of eight, or any other delineation of stroke, no marvellous difference of effect will result. Flight is most likely to be obtained by a *continuous* force.

Of all the numerous models that I have seen during my lifetime, I have observed nothing to surpass in performance the screw-bands rotated by a spring, or wound string, and set free in air. At one time, I tried many of these, made of tin-plate, for the convenience of altering the pitch and beating the surface into form. These usually flew round with circling movements with bird-like performance, and sometimes went away fairly straight to a distance of more than one hundred yards so far out of sight that I lost several. These screw vanes, made out of stamped sheet iron, all to one form, for flying shot practice, are now sold, with a coiled spring projector, by the leading gun-makers in lieu of the hollow glass balls thrown up from a catapult. These screws are remarkable for their stability. From this position they do not deviate till struck by a charge of small shot, when they will sometimes turn a somersault. In my papers of 1866 I gave an estimate of the approximate force required to prolong the flight of such a screw, and found it to be 3H.P. per 100th raised; but this power consumed is far in excess of the reality, as the maximum of economy is at the time of the first start. Towards the end of the flight, when the velocity ceases, there is a waste of lifting power on the ever-yielding air, accompanied by a pitch unsuitable for a decreased velocity. Screw vanes are destined to play a most important part in aërial machines as propellers, and probably in part as lifters; but no model that I have seen has a form of surface adapted for obtaining the maximum of abutment on elastic air. The surface should have an expanding pitch—that is, an increasing angle in a highly progressive ratio. There is also loss from centrifugal force, tending to drive the air outwards. This must be counteracted by curving the surface of the blade downward, the curvature increasing rapidly towards the extremity. The component of these curves will produce a very hollow surface of what has been termed a "conchoidal" form. I intend to test this by making a screw in accordance with these conditions. The principle of aërial flight is not a very abstruse one. In this we have the problem of supporting a heavy inelastic body on a medium of light weight and great elasticity. We can only do this by quickly grasping at a large body or wide stratum of the light element before it has time to yield; bringing the law of first impact or undisturbed inertia into action, to serve as a substantial support. A rapid forward movement in still air appears to me to be the only way of successfully effecting this.

All arrangements acting continuously, with no forward progress, set the air in gradual movement without lifting the weight. In fact, as the speed of "drift" is increased, so is the "lift" increased by reason of the yield of the stratum of air for support becoming less. All this I demonstrated by experiment near forty years ago. I carried my experiments to the verge of personal safety. The constructions were deficient in lateral stability, swerving from side to side like an inverted pendulum. I would willingly have continued to experiment, but then had to engage in more substantial business as a mechanical engineer, from which I could spare neither time nor capital. Mr. Chanute, who has experimented on a large scale, says the condition of stability is one of the most difficult problems in the construction of a flying-machine. It was, no doubt, a deficiency in this respect that caused the death of Lilienthal at one of his celebrated soaring flights. F. H. Wenham.

LOCOMOTION PAST.

[42738.]—IN my present communication I raised the question as to whether any of the first pioneers of land locomotion had taken ideas from the action of animal leg propulsion. I find that some did so, as they could not realise the possibility of propelling a vehicle by road wheels rotated by internal power.

At the beginning of this century Mr. W. Brunton constructed a steam vehicle propelled by two jointed stern legs lifted alternately, just in the way that a man pushes a truck; he named it a "mechanical traveller." Though the engine was 6H.P., the machine only progressed at the rate of two and a half miles per hour.

Another, on a similar plan, was patented by Mr. F. Baynes in 1819.

In 1824 Mr. D. Gordon patented a steam-road vehicle propelled by six legs beneath, having knee joints and elastic soles on the feet, which lifted consecutively. This carriage was made and run on the road. It has been a comical sight with these six legs scampering below, like the Irishman that was thrust in and run through the puddles with a sedan-chair without seat or floor.

In 1825 Mr. G. Gurney patented a similar device acting the same way with legs beneath.

Another grotesque affair was patented by Mr. T. S. Hollander, 1827. This was a vehicle of inordinate length. The method of progress was similar to that of some species of caterpillars known as "Land Measurers," which have a few legs only at the extremities, by which they attach themselves and get along by drawing and throwing their long bodies alternately.

Moral: Don't attempt to imitate nature in terrestrial or aërial machines.

F. H. Wenham.

E. WILSON'S AERIAL SHIP.

[42739.]—WOULD it not be useful if Mr. Wilson would give some explanation of the singular figure you have printed on page 17 of August 18? What are the 14 two-bladed screws (I suppose that is what they are meant to represent) intended for? The stern screw will be a poor propeller. Might I suggest a centrifugal fan, drawing in air from the front, and blowing it out at a great velocity at the stern, would be more effective? G. A. Haig.

BALLOONS IN SECTIONS—ERRATA—ARTIFICIAL WINGS.

[42740.]—BALLOONS constructed in sections—the theory advanced by Mr. G. Parker—is, I regret to say, impracticable when reduced to practice. For instance, when a balloon ascends into the rarefied atmosphere, the gas expands in volume owing to decrease of pressure, thus necessitating the opening of the neck to allow for the escape of the expansion of gas. What would result, then, if, say, "one or more independently controlled sections" remained closed? Of what practical utility would be the other independent section? Not the slightest, I assure Mr. Parker. Again, if it were practicable to open simultaneously all of the sections, this would be tantamount to opening the proper one—to wit, the neck, and with this practical disadvantage that the increase of weight (a great drawback) would be totally useless in extremity.

Errata: Inadvertently, owing to being very much occupied at present, I should be glad if one or two errors may be pointed out in my last two letters. In describing the oblique fall of the eagle (letter 42704), I wrote "vertical" tail for "horizontal" tail; also in letter 42705, helicop*teral* was misprinted for helicop*heral*, whilst in the same letter, *re* the artificial bird system, should be "whatever power is employed to raise the wings, *re-acted* in a downward," &c.; not *reached*. I also, in letter 42704, inadvertently put "fallacy" of this reasoning (page 17, first column), instead of "correctness."

Although I have retired from any further discussion respecting systems of artificial or individual flight, permit me to point out to Mr. Challis that he takes an erroneous interpretation of the flexure and extension of the wing. Gravitation does not do all the work in progression through the air, as the bird's pinions when in action is essentially a forward motion, gravitation largely assisting, of course—an opinion endorsed by the more advanced investigators in the ENGLISH MECHANIC. And that is why, without attacking Mr. Challis, I have found by experiment to be more efficient for my purpose the artificial wing marked Fig. 1, letter 42704, than Dr. Pettigrew's, to form when in action *alternately at will* a kite, screw with reversing planes, or parachute or propeller, precisely similar to the action of bird's pinions in my minor experiments in individual flight. E. Wilson.

EXTREMES.

[42741.]—I PERUSE your useful weekly paper with considerable interest. I, however, differ with a writer of an article you quoted from the *Photographic News* (in your issue of 18th inst., p. 8). Amongst other directions for beginners in the art of photography, they are advised to either aim at under- or over-exposure. My own idea, Sir, is *correct* exposure. How would it do to advise a man to paint—telling him to use too much colour, or not enough; or to tell a man about his diet, that he must eat too much or too little? The wisest plan I have found by my own observation and experience is to obtain a good make of plate (and I agree there is nothing better than Mawson's), it is advisable to have a first-class lens (giving such definition as Wray's secure), and, after such exposure as seems suited to the plate, development according to the plate-maker's directions will give the best possible results. Detail, according to my idea (more especially in photographing landscape, seascape, and architecture), cannot be too clearly shown. A lens should supply for our picture all that the keenest-sighted eyes behold. What do people do when there is a dimness in their natural sight? Why, of course, they obtain the best glasses they can afford to see detail; and so it is with regard to objects at a distance: people are not satisfied to see events without detail, but use opera or field-glasses and telescopes, so that every procurable detail may be observed. I have no sym-

pathy with the hazy photographers, although their pictures obtain prizes occasionally. I am not a prize-winner; but having supplied photographic illustrations for several of the leading London journals, I hope, without egotism, I have gained a position which qualifies me to give an opinion concerning photography.

It is not only in the photographic world we find people going to ridiculous extremes; but if we look at cycling we see some strange absurdities. The man who designed a "bone-shaker" had good common-sense, and saw that a bicycle must be made with a brake for safety, and that a machine must be made of sufficient strength to carry a man safely. Further wisdom was manifested by later manufacturers, who secured strength and reduced weight too. Then the ingenuity of makers introduced mudguards, and the air tire was, of course, forthcoming; then silly faddists began to lead makers, insisting upon having machines too light for safety, casting aside brakes and mudguards, and dropping handle-bars into absurd shapes. Results —of extreme lightness, fatal accidents; casting aside brakes, hundreds of accidents, serious and fatal; dropping of handles, a rider's position about the most absurd in which humanity can be seen to-day—one at which even apes must surely smile. The discarding of mudguards was another fad of "the knowing"; and who has not viewed with pity and disgust the bespattered cyclist returning from a country ride after a shower?

It seems to me, Sir, that extremes are undesirable, and that when writers try to teach people to work against material-makers' directions, or when clerks and others ignorant of mechanical skill try to lead cycle makers, the results are not for improvement of matters, but the reverse.

William H. Morris.

STEREOSCOPES.

[42742.]—The original stereoscope was invented by Prof. Wheatstone about 1840. At that time photography was in its infancy, and the first stereos were such objects as cubes, cones, prisms, &c., drawn as they would be seen with either eye. The spectroscope was a reflecting one, consisting of two mirrors set about at right angles to each other, so that the images of the pictures placed at some distance on each side appeared to unite behind the mirrors. The angle at which the mirrors were placed could be adjusted for pictures of various sizes.

About 1855 or 1856 I made some stereoscopic pictures of Indian temples with an ordinary camera, taking pairs of pictures, shifting the camera about a foot between the pair. Some of the prints were sent to Negretti and Zambra to mount, and they requested me to do them a set, sending me a very perfect stereoscopic camera for the purpose. It had twin lenses like an ordinary binocular camera; the dark slides being square, so that two sets of pictures were made on one plate. The camera could also be set upright, fitting on to a system of parallel bars, an arrangement devised by Mr. Latimer Clark. The photos. were taken so that the right-hand picture was taken on the left-hand side of the plate, and so did not require to be shifted after printing. The camera, with slides, fitted into a box, on the top of which the shifting bars were fixed, the bottom of the box screwing on to the tripod stand. I have lately done some very satisfactory stereos. with a hand-camera, making the exposures first from my right hip, and then from the left.

I do not think that it is very generally known that stereoscopic pictures can, with a very little practice, be seen without a stereoscope. Perhaps the simplest plan of educating the eye is to place two coloured wafers on a sheet of white paper about 2in. or rather less apart. On looking towards them the eyes will tend to converge and form one image. The distance between the wafers can be gradually increased till the eyes can unite them at 2½in. to 3in. apart.

On first trying to unite stereoscopic slides, it is as well to select some with a marked feature, which facilitates the uniting the picture. After a short time, however, there is no difficulty, even if the slides are less marked. The magnifying power of the lenses of the stereoscope is a great advantage if the prints have much delicate detail.

L. Paxton.

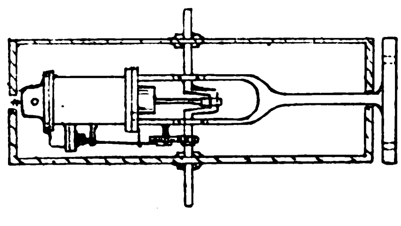
TREATMENT OF DISEASE.

[42743.]—The very able address recently delivered in Portsmouth by Dr. Geo. Wilson, and published in last week's issue of the *British Medical Journal*, ought to give pause of those members of the profession who are doing their level best to persuade the municipalities of the country into endowing researchers in bacteriology. The germ theory of disease is nowhere universally accepted by the closest investigators. It has its opponents in America and on the Continent. English authorities on the subject declare that it is a gigantic mistake. The theory regarding the "police corpuscles" of the blood is now discredited. It is a fable. Many eminent bacteriological experts are strongly opposed to certain forms of inoculatory treatment for so-called microbean diseases. Pasteur's anthrax vaccine is so dangerous to animals and men that it has been prohibited in Hungary, and is condemned by our Board of Agriculture; his rabic virus has actually increased the mortality from hydrophobia. In the English edition of Dr. Lutaud's lecture on Hydrophobia and Serotherapy (published by the Anti-Vivisection Society, 32, Sackville-street, London) it is conclusively proved that the treatment has given what is called laboratory-hydrophobia to many persons not affected with the true disorder. Dr. Wilson has tried the newer methods of preventing disease, and found them wanting. He says boldly that there should be some pause. "The more I have studied them the more firmly I feel convinced that they are based on errors," and he enumerates, with their appropriate epitaphs, the exploded "cures" invented by Koch and Pasteur and their imitators. It would, indeed, be a great mistake to accept unquestionably all the magnificent theories and speculations which nowadays emanate from the laboratories. Joseph Collinson.

53, Chancery-lane, London.

SMALL ENGINE.

[42744.]—Inclosed is a sketch of an idea of mine for a small gas or steam-engine. The feature of it is that the flywheels, instead of being of the usual



size, are very large, the rims of each extending inwards to within 1in. of one another, which is sufficient to admit gas or steam-pipes, also the standard which forms the bedplate of engine. The flywheels are, of course, very light, and have solid webs instead of spokes. This arrangement makes the engine look very compact, and there is plenty of room for an exhaust silencer inside. The engine may, of course, be either horizontal or vertical.

90, Ferry-road, Leith. W. Ewart Gibson.

USEFUL AND SCIENTIFIC NOTES.

Two-thirds of the beef consumed by Englishmen comes from America.

The Hamburg-American line is continuing its experiment with carrier pigeons for the purpose of conveying news from the vessels at sea either to New York or Hamburg. The *Augusta Victoria* recently set several pigeons free during a voyage to New York; one of these homed from mid-ocean, 1,500 miles to Hamburg, within two days(!)

A German patent has, according to the *Journal* of the Franklin Institute, been granted for the treatment of articles of plaster of Paris with an aqueous solution of ammonium borate, for the purpose of hardening them and rendering them insoluble in water. This is said to give results superior to anything that has heretofore been proposed. The solution is prepared by dissolving boracic acid in warm water, and adding thereto sufficient ammonia to form the borate which remains in the solution.

Poultry and Egg Culture.—We continue to talk about the importance of poultry-breeding, and we likewise continue to import eggs to the tune of many millions per annum. We are certainly exceedingly slow, says the *Estates Gazette*, to learn that we could, without difficulty, and with great advantage to the country, provide for our own needs in the matter of eggs and poultry, and Mr. Long seems to think that if he gave a little grant in aid the process would be hastened. Perhaps; but the only true way to encourage the industry is to show that it can be carried on at a real profit. The poultry-crammers make, we believe, a very good thing of it. The breeding and rearing of fowls is, however, a more ticklish business, and it seems probable that, if we are to keep our 14 millions a year at home, instead of sending more and more money abroad, every farmer and miller will have to make the growth of fowls and the production of eggs a well-recognised and properly-managed part of his business. It is obvious that a few millions a year added to the resources of the rural districts would make all the difference in the world. From particulars gathered at the recent Royal Agricultural Society's show we were much impressed with the advance in modern poultry culture, and believe the matter well worth the attention of many country millers.—*The Miller.*

REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96304.]—**American Organ.**—Might I ask what is the object of this funny arrangement of bellows for an American organ, p. 496, and also for some few particulars of that organ, which, according to Mr. H. Bevan Swift (p. 514) was patented in America "some years back"? It seems to be a cranky idea; but there may be something in it, and as we have a sketch on p. 496 of an extraordinary bellows, it would be interesting to learn how it is supposed to work—that is, if it does work.

Organon.

[96305.]—**Motor Cycles.**—The querist has no doubt seen the articles on the subject which have been published recently; but if he wants a general book there is Farman's (Whittaker and Co.), which covers the ground. I do not know of any book which gives details, but the articles on motor cycles, the eighth of which appears in the same number as the query, are about as full as possible. It is not unlikely that the querist has never seen them. No doubt if he sends a specific query he will obtain an answer. N. F. J.

[96315.]—**Fish Tank.**—What does this querist mean? He must have a pump, or some other means of raising the water, so as to get sufficient head to form the jet. As he wants that "without the aid of a pump," he can manage by carrying the water up to a sufficient height, or by having the water supply laid on to the requisite height. There must be something not explained in the query, for that as it stands is simply idiotic. W. M.

[96333.]—**A Monkey Puzzle.**—"Scorpio," on p. 538, says that the moon goes round the earth in 28 days. I think not. I would say it goes round the earth's axis in 28 days. If it moved 28 times faster, it would certainly move round the earth's axis 28 times as fast; but for all that it would not move round the earth. I think S. Bottone and D. J. Carnegie, on p. 538, are quite right: this problem is not easily answered. At least, I think so. Now about those on p. 581. Mr. Bottone is right here again. "Lyttle Booke" is right also. The man could only go round such objects as were in his plane. Further, such objects would have to be stationary; or, if revolving in the same direction, they must revolve at a different and slower rate. I ask this: Suppose the monkey went round faster than the man, or in the opposite direction, what would be the result? I have puzzled myself over this, but can find no satisfactory answer to my liking. To resume, however: A man walks round St. Paul's. Has he been round the cross? No; the cross is on a plane above him, therefore he cannot have been round it, although he may have seen opposite sides of it. He, in order to have been round any object, must not only see opposite sides of it, but he must also be successively at all points of a circuit, being at one time at a place diametrically opposite to where he was at another time. In the case of the cross this is impossible, unless he could walk in air without any support, which nobody can do. The same in respect to the balloon. As for the wheel, if the rim and spokes were to revolve round the hub, the wheel would break. "Lyttle Booke" and "J. H. S." are both right here on p. 581. The rim, spokes, and hub all revolve round the axle, and when the axle is fixed immovably to the wheel, then both wheel and axle revolve round their axis. This axis is a line, and a line has length, but no breadth or thickness. If "Jec" cannot manipulate his house as suggested, let him try the same thing with the turntables found at railway stations. We don't go round the earth in 24 hours, but we go round the earth's axis. "W. J. G. F." is not quite right in thinking that the man goes round if the centre lies within the monkey. If the monkey were the centre, then the case were different; but as "Lyttle Booke" says, this is not possible. "J. H. S." (p. 581) is quite right, I think. The two boxers do not revolve round one another, but revolve round an axis common to both, and being situated either between them or in one of their bodies. I agree with "J. H. S." in regard to the earwig. I also agree with him in regard to the ring. If he held firm hold on it he would not get round it, although he tried for a year. I don't agree with "C. P." (p. 19.) I don't see through his reply as I should like to. As "F. C. S." (p. 19) says, "If the monkey were a geometrical point in the centre of the pole," then it would be possible to go round it. That is just what the monkey cannot be. The centre of the pole is a point, and a point has only position, but no magnitude (or size). Now to "Low Fell" (p. 19) I say, Suppose you did as you suggested with the string, then the string would encircle the pole, but not the monkey. I suggest "Low Fell" to do as follows:—Tie another string to the monkey's arm, both strings being the same length. Now go round a few times. What is the result? The string fixed

in the ground certainly encircles the pole, but not the monkey. The other string does not encircle either monkey or pole. Let "Low Fell" try and see. As the string does not encircle the monkey, he has not been round it. Let him try for himself with a friend instead of the monkey. I mean no disrespect here. I only try to explain as well as I can. To "Scorpio" (page 19) I would say that the man cannot "go" round unless he himself is in motion. The question has aroused a lot of interest, and I would like to see settled what is right.

A. Drysdale.

[96333.]—**A Monkey Puzzle.**—I have been asked to express my opinion on the monkey puzzle, and in order that there may be somewhat less ambiguity of the terms of the question, I would take this opportunity to reply to Mr. Bottone. He says the real question is, "Do we see the other side of the monkey?" Mr. Bottone will pardon me, but the original question did not stand so; if it did, it would not have had any sense in it, so that that reading is out of court, and only the question of real motion remains. If the monkey is in the centre, and rotates on his axis in similar time to the man's obital revolution, then the man has by real motion gone round the monkey in one revolution. If the man turns on his axis in similar time, he will know it by being permitted to see the monkey during the whole time while the different Signs of the Zodiac are marshalled past him, assuming him suspended in space, for it has become an exploded idea that they can go round the man in say, 24 hours, although I begin to think that the Ptolemaic system has still some adherents, and that some believe we don't go round the sun. The monkey, too, will know that the man has been round him by referring to the same signs, but he will deny that the man has rotated. Now take the monkey and place him revolving and rotating, but in an orbit inferior to that of the man. The man will still revolve round the monkey by virtue of his superior velocity in equal time, whilst the monkey will appear to revolve round the man; but it will only be apparent motion. Now place them both revolving in orbits exactly equal, and they will revolve around one another; and if anyone has a difficulty in believing this, let him sit for a little while twiddling his thumbs, and let the thumbs touch as they twiddle, and for once this noble recreation may have proved not a waste of time. The same real motion will exist if they (the man and monkey) are made to rotate as well as revolve, only it will not be so easily seen, the one motion concealing but not cancelling the other.

J. R. J.

[96348.]—**Eczema.**—Querist will find considerable relief in occasionally bathing the affected parts in a cold solution of borax. He must not take too much sugar, on account of its heating properties. Fish is also highly objectionable, especially salmon and mackerel. Ripe, uncooked fruit should be taken daily. If querist can take cocoa he will find it more beneficial than either tea or coffee.

Alpha.

[96372.]—**String and Key Experiment.**—I tried the experiment with the help of my wife and door-key and piece of ordinary string, which I surmise is correct. First I held the string at arm's length and noticed the swinging motion of the key, and at the same time noticed something else. Then I asked my wife to place her hand on mine and stand at right angles to me, and I found that the key made a direct circle. "Please stand this way, about half the distance." She did so, and the key made an egg-shaped circle, so to speak. "Now stand right opposite to me"—and I find the key goes in a direct line again. "Now please breathe at the same time as I do"—and I find the key nearly stops. "Now breathe in opposition to me"—and I find that the key swings with greater vigour.

P. C.

[96379.]—**Motor Car.**—Has "Petrol" noted if his Daimler has lost compression, which might be caused by either the exhaust or induction valves not closing? Has he at any time removed the ignition tubes? If so, in replacing them he may have failed to notice the small steel loose collar which is at the inner end of tube. These may have dropped down and closed the ignition port sufficiently to prevent ignition of the charge. If he will advertise his address, and lives in or near my district (Croydon), I will give him what help I can, as I know the Daimler motor extremely well.

The Writer of the Articles.

[96385.]—**Electric Fishing.**—The so-called electric fishing is nothing but a blind. It is a plain tank, 1ft. deep, 4ft. diam., with a false bottom, which is revolved by an electric motor. The fish are made of tin, with a few hooks soldered to the head and tail. When the false bottom is revolved it carries the fish round with it. The water is mixed with common washing blue, so that you cannot see the fish. Ordinary hook and line are used to catch the fish. A prize is generally given to the person who catches the first three.

R. S.

[96390.]—**Motor Cycle.**—As "Monty" has apparently overlooked this query, I venture to reply. The vaporiser, as shown in querist's sketch, will not work satisfactorily, if at all. The part of wick through which air is drawn is too far from surface of petrol. Follow the design given in the articles on Motor Cycles now running in "Ours."

The Writer of the Articles.

[96426.]—**Magnetism.**—There is no substance known which will prevent the passage of magnetic force in the same sense that an opaque body will prevent the passage of light. The only method is to interpose a screen of iron, as stated by Mr. Bottone. Owing to the great magnetic permeability of the iron in contradistinction to the magnetic reluctance of the air, the lines of magnetic force are diverted along the readier path through the substance of the metal. The best effect will be obtained when the screen takes the form of a hollow sphere surrounding the magnet. The reply by "Regent's Park" is quite incorrect.

W. J. G. F.

[96426.]—**Magnetism.**—No substance is absolutely impervious to magnetism. Some substances permit the lines of force to pass easier than others do. If somebody were to find a substance that would absolutely stop the lines of force, he (or she) would discover "a boon and a blessing to electrical men" in many cases. The best thing to prevent lines of force is to interpose a sheet of soft iron, as, on account of its great permeability, the lines of force select it for their path, and thus it acts as a shield to other objects.

A. Drysdale.

[96427.]—**Boot Polish.**—Yellow wax 4oz., oil turpentine, 8oz. Melt in water bath, strain, stir occasionally until paste turns creamy, then add the following solution: Nankin brown 15gr., phosphin 5gr., water 4dr.; stir constantly until the mixture is perfect. Brown's tan polish and Oxford and Cambridge ditto are two other mixtures, sold by stores and oilmen at 6d. bottle upwards.

Regent's Park.

[96428.]—**Motor Cycles.**—"Worried" can reduce the width of the machine; but it is not advisable. With the width he proposes there would not be so much stability when turning a corner. The bridge-tube, being shorter, would necessitate the exhaust silencer and coil being slung at right angles to the positions given in my drawings, and this would look bad, besides making the connections of the pipes awkward.

The Writer of the Articles.

[96429.]—**Steam Pump.**—"Old Reader" does not give a full enough description of his pump for one to say with certainty what is wrong with it. His description would apply to a Tangye's "Special" pump, but that firm is not dead. If he will send a drawing of valve I will be pleased to help him. What might a "shooting hole" be.

Mabel.

[96436.]—**Motor Cars.**—You must have a differential gear on the driving axle or first-motion shaft. Starley's "Jack-in-the-Box" is the most common. If you have ever attempted to turn an old "Cheylesmore" tricycle to "starboard" with the back-pedalling gear in, as I did once (only), you would have no doubt in the matter.

Mabel.

[96437.]—**Cold in the Head from Bathing.**—Bathing after cycling is one of the worst things querist could do. The best time for a bath is early in the morning before taking any food. If the shore is far distant, it is advisable to walk there slowly, taking a short rest before entering the water. People who bathe in the early morning seldom take chills from so doing.

Aqua.

[96439.]—**Quadratic.**—Both exp. on left must be arithmetically rational, or we should get either a surd = difference between surd and rational, or a surd = a rational. Therefore it follows—

$$\sqrt{(x+3)} = \text{a rational} \ldots\ldots\ldots\ldots (1)$$

$$\sqrt{(x-2)} = \text{a rational} \ldots\ldots\ldots\ldots (2)$$

$$\therefore (x+3) \text{ and } (x-2)$$

are exact squares, and their difference is 5. We find by trial that these squares must be 9 and 4, or—

$$\sqrt{(x+3)} = 3,$$

$$\sqrt{(x-2)} = 2,$$

which gives $x = 6$. If one wished to waste half an hour one might solve by quadratics by taking an assumed value in equation marked (1) thus—

$$\sqrt{(x+3)} = \text{a rational} = a \text{ (say)}$$

$$\therefore x + 3 = a^2.$$

Substituting in (2) squared—

$$x - 2 = a^2 - 5,$$

or—

$$a^2 - x - 3 = 0,$$

when one could find a by quadratics and thus find $x + 3$.

H. C. Donnithorne.

[96439.]—**Quadratic.**—"Inductorium" (p. 20) is not quite accurate in saying that the equation—

$$\sqrt{x+3} + \sqrt{\frac{x-2}{x+3}} = \frac{11}{3}$$

is one "which cannot be solved in any of the ordinary direct methods." It is interesting from the circumstance that *one* value only will satisfy, it being, as already stated, of *one* dimension. It may be put under a simpler form by writing $\frac{x-2}{x+3}$ in its equivalent form $1 - \frac{5}{x+3}$, and by putting $x + 3 = y^2$, whence we have—

$$y + \sqrt{\left(1 - \frac{5}{y^2}\right)} = \frac{11}{3}$$

or—

$$1 - \frac{5}{y^2} = \frac{121}{9} y^2 - \frac{22}{3} y^3 + y^4$$

or—

$$0 = 5 + \frac{112}{9} y^2 - \frac{22}{3} y^3 + y^4.$$

This may be solved by any of the direct methods in use, and gives us $y = 3$—i.e., $x = 6$. Dividing this equation by $y - 3$, we obtain the cubic—

$$0 = y^3 - 4\tfrac{1}{3} y^2 - \tfrac{5}{9} y - 1\tfrac{2}{3},$$

which gives $y = 4{\cdot}546$, or $x = 17{\cdot}665$. Again reducing this cubic by dividing by $y - 4{\cdot}546$, we obtain the quadratic—

$$0 = y^2 + {\cdot}213 y + {\cdot}4132,$$

which gives $y = \pm {\cdot}634 \sqrt{-1} - {\cdot}1065,$

and— $\therefore x = \pm {\cdot}135 \sqrt{-1} - 3{\cdot}623.$

Of these four values, $x = 6$ is the only perfect solution, and the only one which can satisfy the original equation.

West Norwood. Henry T. Burgess.

[96440.]—**Engine Power.**—I suppose you mean resistance in pounds per ton. If so, W. S. Hutton gives: Divide 2,240 by rate of gradient. This is due to gravity. Resistance due to velocity: Rule, square speed in miles per hour, and divide by 171, add 8 to quotient. Add 50 per cent. to quotient for curves, road imperfection, and wind. Tractive power of engine: Rule, multiply square of diameter in inches of one cylinder, by length of stroke in inches, and divide product by diameter in inches of driving wheel. The quotient will be the tractive force in pounds for each pound of effective pressure per square inch on piston, and the quotient multiplied by the effective mean pressure in cylinder gives full tractive force in pounds. Effective mean pressure in piston equivalent to a given tractive force at rails found thus. Multiply diameter of driving wheel in inches by total equivalent tractive force at rails in pounds, and divide the product by product of square of diameter of cylinder in inches by length of stroke in inches. Prof. Rankine gives formula:—Let W = weight to be dragged up; f = proportion of resistance to load on a level; i = sine of angle of inclination of ascent. Then—$(f + i)$ W should not be greater than P, or i should not be greater than $\frac{P}{W} - f$.

Lineham gives in tractive force total mean pressure in both cylinders multiplied by stroke equals tractive force multiplied by half wheel circumference. Or—

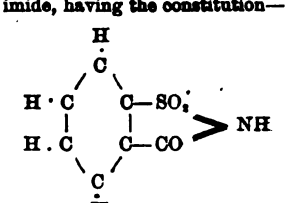
$$2 \times \frac{p \pi d^2}{4} \times l = T \times \pi r$$

$$\therefore T = \frac{p d^2 l}{2r}$$

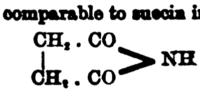
He also gives adhesion per ton on driving wheels: very dry, 600lb. per ton; very wet, 550lb. per ton; average, 450lb. per ton. Greasy, 300lb. per ton; frosty, 200lb. per ton. Prof. Perry gives on pull thus:—The weight multiplied by the coefficient of friction between wheels and rails represents the greatest pull of engine. Suppose weight on driving-wheels to be 15 tons, and the coefficient of friction of wrought iron is about 0 2, the greatest pull is 15 × 0·2 or 3 tons. Coefficient: ·33 for very slow; ·19 for 29ft. per second; ·127 for 66ft. per second. John Goodman, of the Yorkshire College, has much (with formulæ) to say on subject of friction in "Mechanics Applied to Engineering, 1899," of Longmans and Co.

Regent's Park.

[96446.]—**Saccharine as a Food.**—I should like to know what earthly bearing "Regent's Park" considers his more or less incorrect information has on this query. "Saccharine" (so called) is a derivative of benzene — viz., ortho-benzoyle, sulphonic imide, having the constitution—



and therefore comparable to succin imide—



It has a remarkably sweet, though somewhat peculiar, taste. Whether it has a deleterious effect

on the human organism I do not know; but it is sometimes allowed to be used (in cases of gout and rheumatism) when ordinary cane sugar is forbidden. Of course, not being one of the "sugars," which are carbohydrates, it cannot undergo fermentation by means of yeast. I remember some little time ago a query appeared in these columns about it under the erroneous name of "benzole sulf-imide."

Trin. Col. Oxon. J. M. W.

[96446.] — **Saccharine.** — When one reads "Regent's Park's" wonderful reply (p. 584) one feels that saccharine ought, for decency's sake, to turn itself into a sugar as quickly as possible. The habitual use of saccharine is considered harmful. I fancy the particular lesion it induces is renal; but, perhaps, some other correspondent can give a more definite reply. J. DORMER.

[96455.]—**Shoes without Heels.**—I wish to say the idea is behind the times, as the Americans have worn them for years, if I remember rightly, under the name of "common-sense" shoes. P. C.

[96460.]—**Dissolving Amber.**—Much obliged to Mr. Bottone for his reply on p. 21; but, unfortunately, it does not touch my question. I am quite aware that amber can be dissolved, but what I want to know is exactly what I stated in my question—how is it dissolved according to the recipe given on p. 494, reply 96271. The directions seem full and clear enough for the other ingredients, but there is not a word about how to dissolve the amber. That is the crux. I asked distinctly (p. 535) whether any reader would look at the recipe and tell me how the amber is treated to make it mix with the other ingredients. T. I. A.

[96461.]—**German Baths.**—I suppose I ought to be much obliged to "Regent's Park" for his reply on p. 21; but, as a matter of fact, I am not. The correspondent has simply misunderstood my query, and has given an extract from some book which I could, no doubt, have found myself. What does he suppose the analyses he gives have to do with my question? And there is no answer at all to the real question. No doubt the correspondent means well, but good intentions pave the way, &c. LITHIA.

[96462.] — **Wimshurst.** — Paraffin varies very much in resistance, and also in hardness. It has the disagreeable property of absorbing freely the acid perspiration of the hands, when it becomes a very poor insulator. Add to this that the brushes sweeping along the paraffin get their lips greased—you quite understand the machine won't work. It may also be that you are using hollow glass tubes instead of solid glass rods or Leyden jars. Then the machine will certainly not work. S. BOTTONE.

[96464.]—**Great Laxey Waterwheel.**—Replying to "C. C.," I beg to say that the wheel and all the gear attached to it were designed by the (at that time) village millwright, a Mr. Casement, father of one of the present chief engineers in the employ of the Isle of Man Steam Packet Co. For more than forty years this wheel was the largest in the world, and has always been regarded by the best professional engineers as the best-designed wheel for its work extant. It says much for the ability and courage of a plain country mechanic. I am personally acquainted with the son of the builder, and can vouch for the above remarks being accurate. J. J. KERMODE.

[96465.]—**Telephone.**—If you will refer to my little book, "Electrical Instrument Making for Amateurs," you will find a full description of the way of making a pair of telephones suitable for your purpose. S. BOTTONE.

[96466.]—**Length of Link.**—The principal distance you require is distance between eccentric-rod eyes. To the travel of the valve add the lead × 3; this will give centres; then, by measuring off length of half-block from centre, to which add ¼in. longer at suspended end for play in working, ½in. at far end. The go-astern is usually placed at the farthest end from suspension on account of wear, which is greater. Strike out radius of link from centre shaft, allowing sufficient in valve-rod for eye to clear the gland-nuts when highest; also the link. MONTY.

[96468.]—**Filling for Wood.**—In the Continental system of French polishing, the rubbers are made of old worsted stockings. After papering work all right, take rag, shake some plain polish on the work, rub in, which opens grain clogged by papering, polish acting also as a binder. Then oil in well to bring out colour of wood requiring it. Next fill worsted rubber with spirits, and rub in well ground pumice into grain of wood. With this exception use coarser rag in bodying in. Keep on rubbing, and supply rubber with spirit as required. Do not commence using polish or oil until a hard cold surface free from gloss, with grain that looks well filled, is observed. Allow work to stand some time · the longer the better. You may notice cavities of a minute character perhaps. If there is any accumulation of powder, put job aside, and when hard paper down before starting again. To judge of job it may seem as if primary filling-in had sunk deeply into wood, but when surface is touched with a little paper it will be found otherwise. When ready to proceed further, take spirits and pumice powder, but less in quantity, working firmly and steadily. When necessary add a few drops of polish, but no oil. If rubber drags, a little drop more spirit until the time comes for bodying up. Proceed gradually if job is worth it; take it up five or six times before spiriting off. If only dry polished—i.e., polish without oil being used in first or second stage—grain has tendency to rise. If so (often with maple), then level down with fine paper; but after preliminary coats are applied, the round felt rubber with oil and pumice-powder to fit for forwarding. Woods of open grain are sometimes filled by rubbing polish and pumice-powder, using colouring matter according to wood used. The American employs silica process for filling in, and the Continental workman fills up with two or three coats, confining himself to use of polish and spirit instead of hard drying oils. REGENT'S PARK.

[96469.]—**Rubber Stamp.**—The mixed rubber must be bought ready for use, as it requires machinery to mix it. Curing temp. about 290° Fahr., but varies with different mixings of rubber. See my advert.

West Didsbury. M. COLE.

[96470.]—**Friction of Water in Pipes.**—To calculate friction of bends $h = v^2 \times \text{sine}^2 \times$ number of bends × ·0003, where v = velocity of water in pipe or stream in inches per second. Or, multiply square of v by sine of angle of bends (of which the resistance is to be estimated), and the product by the constant ·0003, the result expresses resistance; h = head in inches necessary to overcome angular friction, which varies as square of velocity, and of sine of angle of bend with the straight line of direction. When the angle is reversed, or more than 90°, the square of the sine of the complementary angle + 1 must be used. The velocity for computation is, of course, that theoretically due to fall, and loss by bends must be deducted from head, discharge being calculated from reduced slope. Loss of head varies, not only according to size of angle, but also to volume to be carried; perhaps best expressed by square root of hydraulic mean depth in feet; loss of head being divided by this quantity to give final resistance. When hydraulic mean depth falls below unity, tabular numbers are increased as square of such depth. With pipes, this is quarter of diameter. Increase of resistance h will be $= v^2 \times \text{sine}^2 \times$ number of bends × ·0003, divided by $\sqrt{\frac{d}{4}}$, or friction against sides may be found by Prony's rule: Multiply 2·25 times length of pipe in miles by the square of the velocity of water in pipe in feet per second, and divide product by dia. of pipe in feet equal head of water in feet required to balance the friction. Friction increases nearly as the square of its velocity for bends in pipes. These diminish velocity by ·0039 times the sum of the sines of the several angles of inflection, sharp turns to be avoided. Blackwell's rules for pipes:—To find velocity in feet per second multiply dia. of pipe in feet by the inclination of pipe in feet per mile, divided by 2·3, and extract the square root. To find dia. of pipe in feet multiply square of velocity in feet per second by 2·3, and divide by the inclination of pipe in feet per mile. To find inclination of pipe in feet per mile, to be given to overcome friction, multiply square of the velocity in feet per second by 2·3, and divide product by dia. of pipe in feet. REGENT'S PARK.

[96474.] — **Colouring Rubber.** — Rubber, like other substances, loses its new look with usage. You can do a little to improve by rubbing with fine powdered French chalk. Vulcanite, polish with rouge or putty-powder.

West Didsbury. M. COLE.

[96476.]—**Absolute Temperature.**—For every degree Centigrade of rise in temperature a gas increases $\frac{1}{273}$ of its volume. One cubic foot of a gas, measured at 0° Cent., will, therefore, at 273° Cent., measure 2c.ft. Similarly, if the temperature were lowered to − 273° Cent., the contraction would be equal to the volume, therefore the gas would cease to exist, and consequently the motion of the molecules would cease, and the temperature will, therefore, have reached the absolute zero. It is from this zero that absolute temperatures are measured, and are clearly degrees Centigrade + 273, i.e., 0° Cent. = 273° absolute, 10° cent. = 283° absolute, − 10° cent = 263° absolute, and so on. The boiling-point of liquid hydrogen is about − 220° Cent. Correctly speaking, there is no such thing as the "temperature of space," as temperature cannot exist apart from matter. A thermometer placed in space would receive radiations from all sides, and the temperature indicated would depend on the number of radiations received and transmitted into heat motion within the substance of the thermometer. W. J. G. F.

[96476.]—**Absolute Temperature.**—A theoretically perfect gas contracts $\frac{1}{273}$ of its volume for every decrease of 1° C., and expands $\frac{1}{273}$ for every increase of 1° C. in its temperature. Hence it is assumed that 273c.c. of such a gas at 0° C. and 760mm. would occupy no space at all at − 273° C. Therefore when such a gas has contracted to nothing at all it is assumed that the lowest possible temperature has been reached, or, in other words, complete absence of heat. Therefore, − 273° C. is called the "zero of temperature." True temperature or "absolute temperature" should therefore be measured from − 273° C., which should be called 0° A (A = absolute). That is, the melting point of ice (only an arbitrary starting point when called 0° C.) should be 273° A, and the boiling point of water at 760mm. pressure, 373° A. Interstellar space is surmised to be suffering from complete absence of heat, and therefore its temperature should be 0° A, or − 273° C. The boiling point of liquid hydrogen is about − 212° C. or 61° A. TRYTOAID.

[96479.]—**Bunsen Burner.**—A Bunsen gives more heat and burns less gas, besides giving a clear, unsmoky flame, than an ordinary burner. The one which you describe constitutes the ordinary Bunsen with rose top. W. EWART GIBSON.

[96479.]—**Bunsen Burner.**—The advantage of the Bunsen burner is that the gas is first mixed with air, and this insures perfect combustion. In an ordinary burner only the gas on the exterior of the flame is burning. The luminous portions consists of incandescent carbon giving light but little heat. The carbon burns when it arrives at the outside, and is in contact with air, and therefore oxygen. In the Bunsen the admixture of air insures combustion taking place all through the flame. Further, the flame is non-luminous and smokeless. Vessels heated over it are not blackened with soot. Of the two burners mentioned the Bunsen would give the most heat for the same quantity of gas. A. DRYSDALE.

[96481.]—**Defective Dynamo.**—To MR. BOTTONE.—In all probability there is a leakage between iron and wire, either on the armature or field-magnets. Supposing this not to be the case, you can easily find out in which way the machine ought to be driven by connecting it up to a battery, and noting in which may it runs as a motor. When, if you have arranged it in series, it must be driven in the opposite direction to which it runs as a motor. But if you arrange it in shunt, it must be driven in the same direction as it runs as a motor. One point is very essential: the brushes must be arranged so as to rest on the slits when the iron portions of the armature face the iron portions of the tunnel. S. BOTTONE.

[96482.]—**Insects in Floor.**—Open all your windows in your dark-room, remove therefrom lights, candles, &c., so as not to have an explosion. Now procure a quart or two of benzoline, and about 2oz. of naphthaline (also called albo-carbon). Dissolve this in the benzoline, and go carefully over the floor with a clean, dry whitewash brush, and soak the floor thoroughly all over with this mixture. Now close all windows and doors of the room, and let no one go near the room for 12 hours; then, avoiding all candles, lights, or fires, throw open all the windows and doors so as to ventilate the room thoroughly. There won't be an insect left. S. BOTTONE.

[96482.]—**Insects in Floor.**—Try chloride of lime, as solution or dry powder. Pennyroyal oil sprinkled about clears of fleas, and it may have some effect on your pests. Benzine 10 parts, soap (soft, convenient) 5 parts, water 85 parts, sprinkled about. Avoid lights. REGENT'S PARK.

[96483.]—**Speed of Water-Wheels.**—General rule for H.P.: Multiply weight of cubic foot of water, 62·4lb., by number of cubic feet falling per second; multiply product by height of fall in feet, and divide by 550, quotient equal available theoretical H.P. of that fall. Overshot: Diam. of wheel from 1 to 1¼ height of fall, speed of circumference 4ft. to 5ft. per second, efficiency 60 to 70 per cent. High breast: Diam. of wheel 1¼ times height of fall, speed of circumference 5ft. per second, efficiency 75 per cent. Breast-wheel: Diam. of wheel twice the height of fall, speed of circumference 5ft. to 6ft. per second, 55 to 60 per cent. Undershot-wheel: Where fall is under 5ft., diam. of wheel 12ft. to 20ft.; speed of circumference = ·50 of velocity of water, efficiency 25 to 33 per cent. Paddle-wheels: Diam. of wheels 14ft. to 20ft., speed of circumference = ·50 of velocity of water, efficiency 25 to 33 per cent. Poncelet's undershot-wheel: Curved floats for falls under 6ft., diam. of wheel 10ft. to 20ft., speed of circumference 8ft. to 12ft. per second, 55 per cent., &c. See W. S. Hutton further for diam. of journals or necks; also formulæ for turbines. REGENT'S PARK.

[96484.]—**Cubical Contents.**—Draw a cross-section of the embankment, and from the tops of the slopes let fall two perpendiculars to the base. The cross-sections will then be divided into a central rectangle, 17ft. by 10ft., and at each side a right-angled triangle, of which the sides containing the right angle are 30ft. and 10ft.—since the slope is 3 to 1. These two triangles are, therefore, together

equal to a rectangle 30ft. by 10ft. The total square area of the cross-section is, therefore, 170sq.ft., + 300sq.ft. = 470sq.ft., and the cubical contents of the bank 470 × 300 = 141,000c.ft. Were the ground not level, the problem becomes more complicated, as each slope is then the frustum of a prism.

W. J. G. F.

[96489.]—**Wimshurst Experiments.**—You must drill some holes in the main balls of the prime conductor, and having procured the sufficiency of 7/20 stranded cable covered with good insulation up to at least 750 megohms resistance, you connect these to the holes in the balls, having bared them of covering where they have to enter the holes, and take them to your jars, or other things you wish to charge. To get pith balls to dance, you must see that one wire is connected to lower plate, and one to upper ball. You must put the ball and plate as far apart as you possibly can, and you must turn the machine very slowly, otherwise you get sparks instead of attraction.

S. Bottone.

[96492.]—**Two-Speed Gear for Motor Tricycles.**—The simplest arrangement for this is in form of old sun-and-planet gear, now better known as Crypto gear among cyclists. It consists of an external-geared wheel, which contains an internal geared ring, into which four small pinions, placed equidistant, work, these in turn gearing into spindle, which in some has a hollow sleeve fitted over it, cut with gear inside and out. By means of sliding this sleeve or bush in and out, it is possible to obtain a two-speed gear, and also a free wheel or pedal. The Crypto gear works well and silently, and works far better when gearing down than it did in form first applied to cycles as hub for the geared Ordinary bicycle. I regret having no time to make drawings of same. The sliding bush is a Manchester firm's patent; don't waste time trying to reinvent it, being fully covered. The Crypto gear, with its many forms, can readily be obtained from makers, for whose address look up advts., either in this or any cycling paper.

Monty.

[96494.]—**Wireless Telegraphy.**—Yes; but very slowly indeed.

S. Bottone.

[96499.]—**English Lever.**—In your issue of the 18th inst., Mr. P. Dewar asks some reader to let him know if Swiss made watches are good time-keepers. I would inform him that he will find in my reply 94949, which appeared in your issue of February 3rd, p. 589, an example of Swiss watch performance. It shows excellent timekeeping, considering that the price of the watch, in silver cases, was only 45s. If Mr. Dewar wants to purchase a watch of very high quality, he should also read my reply, 95279, February 24th, as it will give him some useful hints on the purchase of watches. The Swiss, of course, make far better watches than the one I referred to, as that was only a very cheap one which I bought simply for an experiment, having been told what a marvellous timekeeper this class of watch was at the price it would be sold at. But as an example of what the Swiss can turn out in high-class watches, I would mention that Mr. Montandon-Roberts, of Geneva, has been for some time past sending watches of his manufacture to Kew Observatory, and that in the years 1896, 1897, 1898 he received no less than 85·7 A marks on the average for the *twenty* watches he has sent up for those annual competitions. I consider this shows a fine example of clever and accurate workmanship, seeing that this average is for a fair number of watches, and not simply a solitary example. I am glad to see that several of the Coventry watch manufacturers also compete at the Kew Observatory trials, and gain high results.

Kingswood.

[96501]—**Oil and Gas-Engines.**—The design in the articles on "Motor Cycles" is entirely unsuited for a stationary engine. In the first case lightness is aimed at, and economy and durability are necessarily subordinate, while in the stationary type all consideration should be for steadiness, efficiency, and durability.

Trytoaid.

[96502.]—**Cement for Cork.**—See reply No. 96352.

S. Bottone.

[96502.]—**Cement for Cork.**—Nothing better than rubber solution as used by waterproof-garment makers; that sold for tire repairs is too thin. Smear the surfaces, allow to dry, then put together and hammer slightly. The cork must be cut so as to fit together to form a solid lump.

West Didsbury. M. Cole.

The Machinery and Electric Lighting Committee of the Glasgow International Exhibition, 1901, have agreed to accept as exhibits for producing steam for electric lighting and motive power the following:—Lancashire boilers from Messrs. Penman and Co., Glasgow; water-tube boilers from Messrs. Babcock and Wilcox, Limited, Glasgow; Messrs. Stirling and Co., Limited, Edinburgh; Messrs. Weir, Limited, Cathcart, Glasgow; Mr. W. E. Berry, Manchester; and Messrs. Penman and Co., Glasgow. It is estimated that the total power required will be about 5,000H.P.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

QUERIES.

[96504.]—**Macadam.**—Where can I find an authentic account of Macadam's directions for making the road surfaces known as macadamised? It is stated that in many cases our roadmakers use stones too large, and it certainly seems like it from what can be seen on the Embankment now.—Via.

[96505.]—**Lithia.**—Which is a suitable form of taking lithia for the purpose of eradicating uric acid from the system?—Aqueous.

[96506.]—**Figure of the Earth.**—It seems, by the nebular hypothesis, that the present oblate-ellipsoidal figure of the earth may not have been its shape in earlier times. What proofs can be adduced to show it had attained its present figure in, for instance, the Palæozoic period, or even later?—J. D.

[96507.]—**Lawn Tennis.**—In the "Lawn Tennis Handbook" it is stated that the average length of a game was calculated some years ago to be 4·6250 strokes. This appears to be too low an estimate, considering that the minimum number of strokes required to win a game is four, and that the maximum is indefinite, owing to the "deuce-'vantage" method of scoring. How was the official estimate arrived at?—H. L. S.

[96508.]—**Motor Cycles.**—I have read the articles now appearing on this subject with much interest, and should be glad if the writer of the articles or other kind friend would inform me how to make a core-box for the cylinder cover and valve-box. I have left the prints on cylinder cover cavity ⅝in. long and valve-box prints ⅜in. long. I should like to know the dimensions of ignition and exhaust box on cylinder cover.—G. S. Deadman.

[96509.]—**Resistance Coil.**—Could Mr. Bottone or other readers tell me how to make a spiral resistance coil with 2lb. No. 22 iron wire? Also what size windmill should I want to give ½H.P.? A sketch of mill, if possible, and dimensions would oblige.—W. Pretty.

[96510.]—**Coppering Carbons.**—I have recently recoppered some carbons of a bichromate battery, and wish to paint the copper deposit with something to prevent creeping. I believe pitch dissolved into a varnish with some kind of spirit is what is mostly used, and I shall be glad if one of "ours" will confirm this, giving the name of the spirit necessary to dissolve the pitch.—A. R. Barrett.

[96511.]—**Brazing Lamp.**—Will any correspondent give me a sectional diagram showing the principle of any powerful brazing lamp?—E. M. S.

[96512.]—**Electric Lighting.**—I am desirous of lighting my shop window by two incandescent lamps during the coming winter. Will someone please show me the cheapest way of doing this?—A. R. P., Ledbury.

[96513.]—**Hereditary Insanity.**—Will one of "ours" kindly answer the appended question? Facts: Father of family in his youth was dissipated, married, and had children. Two years after birth of youngest became insane through paralysis of the brain, died five years later. Youngest child now 16 years old, and all are particularly intelligent. Are they or their children likely to develop insanity? No insanity previously in family. Anxious.

[96514.]—**Dry Cleaning.**—Can any of "ours" kindly give full particulars of the dry-cleaning process as done at the large cleaners? I do not think it is a patent or secret process.—W. Nash.

[96515.]—**Model Steamer.**—I am building a model steamer, 3ft. long, 6in. beam. I propose to use the boiler, cylinders, &c., of a small model locomotive. I should like to know if you think they are powerful enough to drive it? The cylinders are single-acting, oscillating, ⅜in. bore by ⅝in. stroke. The boiler has one tube through it from spirit flame to the funnel. If I put another tube, so as to increase heating-surface, shall I want a stronger safety-valve? Where the propeller-shaft passes through the stern, will it have to go in a long tube reaching inside the boat to the water-line, or shall I only want a short piece of tube?—Green Hall.

[96516.]—**Heat Consumed in Mechanical Work.**—If air of a specified temperature and pressure is supplied to an engine, what is its pressure and temperature on leaving engine? What would be its temperature if simply allowed to escape in the atmosphere?—W. T. H.

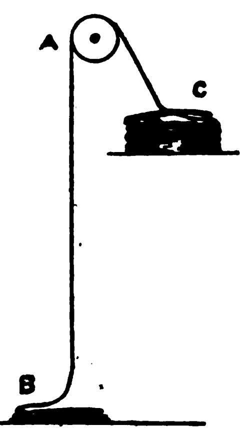
[96517.]—**Clarifying Methylated Spirits.**—I have a quantity of methylated spirits mixed with equal parts water and a little colouring matter, and as the mixing of the water with the spirits turns the whole to a colour resembling milk, I shall be obliged to any reader for information of a simple method whereby I can clarify it and bring it back to the original clear appearance before being mixed?—Glasgow.

[96518.]—**Charging Accumulators.**—I am charging motor-car accumulators by means of a plating dynamo 6 volts, 50 ampères. What is the best arrangement for charging, say, four cells at once—in series or in parallel, or both? What voltage and ampèrage should be employed, and how long should the accumulators take to become fully charged? How can their condition be correctly ascertained? I shall be glad of any definite information on the subject.—E. A. W.

[96519.]—**Water Power.**—Will anyone kindly explain whether a 4in. pipe 100ft. long, with 10ft. head, will discharge freely into space the same amount of water as a 4in. pipe 1,000ft. long with 100ft. head (the mean hydraulic gradient being the same), and if this be the case, would the latter give a greater horse-power than the former, and reason why?—J. F. B.

[96520.]—**Velocity of Light.**—Will some expert on the properties of light kindly inform me whether the relative velocities of red light and of violet light in space have been ever accurately determined, and with what result, and in the same manner as arrived at by Foucault and others for white light? I do not mean the number of wave-lengths per second, for it has been usual to assume that the velocity of white light divided by the wave-length of any colour will give the velocity of such wave-length. And would anyone also say whether sound of high pitch travels through air with the same velocity as that of a low pitch?—J. F. B.

[96521.]—**Speed of Falling Chain.**—Let A be a pulley, C a coil of chain of great length, which can "pay out" easily, B the bottom of a pit. Let A be 580ft. from B. Supposing that the chain be allowed to run freely over



the pulley to the bottom of the pit. The chain will therefore start from rest at C, fall 580ft., and then settle down at rest at B. If this be kept up for a length of time, would the chain not have a uniform velocity all the while, and would the velocity not be equal to mean velocity at the end of each second of time of a free-falling weight—i.e., a free-falling body would at six seconds have a velocity of 193ft. per second, and fallen 580ft., but as the chain is linked together, there would be a retardation tendency of the advancing part. Hence I assume that, taking the velocities at 1, 2, 3, 4, 5, and 6 seconds, the mean would be about 113ft. per second—neglecting friction. As there would be a certain tension on the chain, would it not be greater near the top than at the bottom, for the chain has to start from rest and suddenly take up 113ft. per second speed? Would someone kindly help me out?—J. F. B.

[96522.]—**Electric Motor.**—Will one of our electrical friends kindly give the dimensions of a motor suitable for driving a coffee-mill? Capacity, 200 volts at 8amps.? Also—(1) What is the least power motor that can be economically designed—i.e., without excessive loss in armature and magnet coils, to run off 210 volt mains? (2) Will ring or drum armature give best results? Gauge and number of convolutions required. (3) Will series or shunt be best for magnet coils? Gauge and number of turns required. (4) Can it be run at 1,000 revs. per minute? What variation of speed will resistance of 10 ohms effect, five coils in series, each 2 ohms? (5) Should a well-designed motor when driven as a generator give as good results as it would have done if it had been designed as a dynamo?—E. B. L.

[96523.]—**Water Lifting.**—Can any reader experienced in the above tell me the cheapest and most efficient means by which I can force 20,000 gallons of waste water (in about two hours) from a tank to a meadow about 500 yards distant? The top of the tank is level with the ground, but the meadow is about 33ft. higher than the bottom of tank. The apparatus must not be liable to clog. I have a 10H.P. steam-engine, which is 25 yards from the tank.—Redbun.

[96524.]—**Automatic Flushing Cistern.**—Will someone please give a working sketch and explain the construction of the automatic cisterns used for flushing urinals?—Householder.

[96525.]—**Phonograph Shaver.**—Can any reader give me any information as to the best method of grinding and polishing a sapphire shaver, which has not a very good edge?—R. T.

[96526.]—**Fly-Catchers.**—Can any of "ours" inform me what ingredients are required for making sticky fly-

papers, also those now sold called "Tanglefoot"? I cannot get any chemical fly-papers now. How can I manufacture some? I have some powder arsenic.—PESTERED.

[96527.]—**Fish-Plate.**—I have a lot of railway fish-plates to set thus, which is a slow process, being heated in

a smithy fire and set with a handle and screw. Could any reader suggest a machine to be driven off a 3½in. shaft which would give the same set? Also a small furnace to heat plates in?—FISH-PLATE.

[96528.]—**Chemical Action.**—Kindly state the chemical action likely to occur by mixing a water solution of permanganate of soda with sulphuric acid, and the probable effect of adding such a mixture to crude town sewage?—J. HAMSON.

[96529.]—**Duffett's Battery.**—Can anyone tell me how long Duffett's battery will deliver a current of two ampères? Also is there any local action when cell is idle? If so, to what extent?—i.e., how many hours will it take to polarise through local action alone?—F. RIGBY.

[96530.]—**Alternator.**—Would Mr. Bottone or some of our electrical correspondents kindly reply to the following? Is there any difficulty in running alternators made by different makers in parallel? If so, what is the difficulty? Also, is it necessary to have a synchroniser on the switch-board when running alternates in parallel? What is the advantage claimed of a synchroniser?—R. S.

[96531.]—**Heating Power of Coal.**—Can any readers inform me whether any book or work is published which gives information as to the heating power and durability of the various kinds of house, hard steam, and Welsh coals?—ENQUIRER.

[96532.]—**Geometric Solution.**—In issue of Aug. 4 "J. S." kindly gives construction of this difficult problem. Querist finds himself unable to understand reasons. Would "J. S." be so good as to give proof, and say how are the lines G P, G Q, G R drawn? Might the points 1, 2, 3 happen to fall on same straight line?—M. C. F.

[96533.]—**Liquid Fuel.**—I am fitting up a small launch, 20ft. long, and am thinking of using liquid fuel. I shall feel obliged if some reader of experience in this will inform me the best burner and the cost of running compared with coal. The boiler is vertical, with bottle tubes, and brass tubes from firebox through side of shell. I think it is on Kingdon's pattern. Grate 12in. diam.; engine 3½in. by 4in. stroke. I require about 300 revs.—C. J. F.

[96534.]—**Dental Chair.**—Will some ingenious friend kindly give me a hint or two as to the home construction of a cheap but efficient dental chair—one that can be raised and lowered and fixed at any inclined position? I find it most trying to the back and head using an ordinary chair, with cushions arranged for head, &c. I started dentistry because of the prices charged by dentists and was successful "first shot" in supplying myself with 18 teeth on vulcanite. I have since made several sets and partial sets in vulcanite, gold, combination, &c., for friends at half ordinary prices.—DENTURE.

[96535.]—**Flagstaff Stays.**—Will one of "ours" kindly supply particulars of wire stays necessary for a pole 50ft. long, on top of building, gauge of wire, and where to fix them?—ROYAL STANDARD.

[96536.]—**Crucibles for Silver.**—I am engaged in the melting of silver. The crucibles hold about 2,000oz. The difficulty is that the silver eats into the crucible, and causes waste. The crucibles are made of plumbago. Can any reader tell me what to mix with the plumbago that will prevent the above difficulty?—LUCKCOCK.

[96537.]—**Electric Lighting.**—To MR. BOTTONE.—I must thank you very much for your reply No. 96389 in last week's "E.M.," but am not quite clear on two points. (1) Which main ought the automatic cut-out to be—on positive or negative? also main switch? (2) Will not the lamps get more than 50 volts when running at 65 volts? If not, please explain why.—W. H. C.

[96538.]—**Gravity.**—What is meant by the "instantaneous propagation of gravity"? Are we to understand by this phrase that the earth's attraction acts through infinite space without any relation whatever to time, or that it acts so quickly through great distances that its velocity is incalculable? I should be obliged if any of your readers will explain, and give the data upon which the idea is founded.—HUGH ALEXANDER, Sowerby Bridge.

[96539.]—**Ebonite Boxes.**—Could any of the readers of the "E.M." give me a recipe for stopping up cracks and holes in ebonite boxes which are used for accumulator cells?—ACCUMULATOR.

[96540.]—**Cycle Motor.**—Will "Writer of the Articles" kindly say if there is any tendency to drive the crankshafts out of line with each other when running? It seems to me that there is with the present method of construction. Should not the crank-bolt carrying the hardened steel sleeve be keyed some way to discs? Also, I should be pleased to hear if the writer has tried raw hide for the large gear-wheel. Not surprised to hear that the pinion made from this material wore itself out so soon, as the wear is so much greater on the pinion than on large gear-wheel. Trusting these queries will come under his notice—MOTOR.

[96541.]—**Carburetter for Motor-Cycle.**—I am much interested in the current articles on Motor-Cycles. Will the writer of the articles, also "Monty," please give their opinion on the advantage or objection to running the baffle-plate down into the petrol., so that the air must pass through the spirit before passing through the wick? Would not that method give a more thorough carburetting of the air, and also allow the use of petrol. of a lower specific gravity? Is there any objection to placing a light lifting check-valve just above or below the gauze, as an additional precaution against back-pressure into the carburettor in case of back-fire?—BETA.

[96542.]—**"Nordrach" Treatment of Consumption.**—Will any reader kindly give me any particulars of the system pursued by Dr. Otto Walther at his sanatorium at Nordrach, in the Black Forest, which is known as the "Sanatorium" treatment, the "Nordrach" cure, or open-air cure?—CONSUMPTIVE.

[96543.]—**Sundial.**—Can anyone inform me what would be the best cement to use to fasten the style of sundial down to the face of the instrument? The style is of brass, the face of slate. There are brass pins that go down into the face; but they have worked loose.—NAUTICUS.

[96544.]—**Lard Refining.**—Please give me particulars of lard refining, suitable for about 40lb. or 50lb. weekly. For what use are the oils chiefly? Any information will be esteemed a favour.—J. M. STUBBS.

[96545.]—**Rubber Rings.**—Having a number of gauge-glass (rubber) rings which have grown hard and thus useless, the cause of which is, I expect, owing to their having been exposed to the air for some time, I would be much obliged if someone could tell me how to put them right, or, failing that, how I could utilise them?—R. DOW.

[96546.]—**Motor Batteries.**—Will some reader kindly give me advice about the above? When my motor (De Dion Quad) was new the dry batteries gave from 7 to 8 ampères. After running about 500 miles they only gave from half to one ampère. This not being enough, I ordered a new set (which are very expensive), and dissected the old ones. After chipping away the pitch which seals the battery, I find that the case of cell itself is of zinc and forms one pole of battery. The other pole is the ordinary carbon surrounded by a composition that looks like plumbago paste, which is wrapped in canvas. Between the canvas and the zinc case there is sawdust, damped with what tastes like salammoniac and water. I find that the sawdust nearest the walls of zinc case is dry, I suppose because of the hot weather. Is this a reason for the battery getting weak so soon? Will some kind reader tell me how to renew the chemical next the carbon, what the composition is, and would fresh sawdust re-damped give the battery new life? It seems absurd to throw away the battery when the zinc case is not a bit corroded by galvanic action. I shall be very glad of any information on the subject.—SAUREY.

[96547.]—**Saturn.**—Will some astronomical friend kindly give a sketch in "Ours" of this planet, as he now appears, for the guidance of those who have not been able to view him on account of his great S. declination?—S. S.

[96548.]—**Bent Timber.**—Will anyone kindly say what smaller curve it is necessary to give to a piece of timber that has been steamed to be bent, so that when it springs after removal it may assume the correct curve that was desired?—DOUBTFUL.

[96549.]—**Encke's Comet.**—Can any of "ours" oblige with the time of the last perihelion passage of above, which took place about 1898, May 24?—W. S.

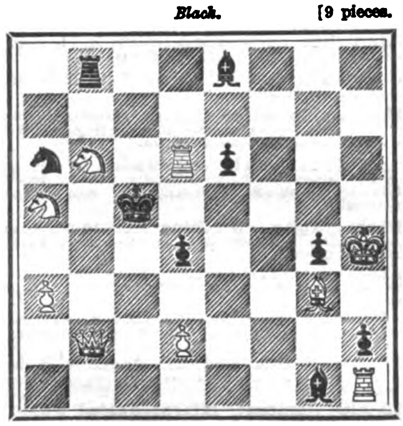
[96550.]—**Mensuration.**—Will one of your mathematical readers kindly show the working out, by mensuration, of the following? A circle is described about a regular hexagon, and a second hexagon is described about the circle. The difference between the area of the two hexagons is 813sq.in. Find the area of the circle.—PUZZLED.

CHESS.

All communications for this column to be addressed to THE CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1689.—By H. VON DUBEN.

Black. [9 pieces.



White. [9 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Sept. 4.*)

Solution of PROBLEM No. 1687.—By P. G. L. F.

Key-move, K-B 6.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1687.—Correct solutions have been received from Mary R. Phillips, J. E. Gore (also No. 1686), Richard Inwards, Quizco, F. B. (Oldham), T. Clarke, A. Tupman, Rev. Dr. Quilter, Whin Hurst, Hampstead Heathen, Mahtale.

FORTY-ONE warships were launched in Great Britain during 1898.

THE judges of the Liverpool Self-propelled Traffic Association have decided not to publish any figures whatever, further than those already issued, until the publication of the report about November next.

ANSWERS TO CORRESPONDENTS.

. *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

. Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, August 23, and unacknowledged elsewhere:—

ALEX. B. MACDOWALL.—Scorpio.—O. G. A. P. or ——.—Louis Senecal.—W. Ewart Gibson.—C. W. Krohne.—Electric Engineer.—D. M.—Ivo H. Carr Gregg.—C. J. Charnock, Sereda, Russia.—W. H. B.—Ajax.—W. Ritchie.—T. L. Spencer.—A. Caplatzi.

S.—Do not know it. Storage batteries are not novelties; but if someone has invented a superior device he should make it known in the usual way. Anything really good will always find space in our columns.

L. S. D.—In the back volumes you can find the particulars desired; but you do not specify the size of the boiler. If a book is wanted, try Alexander's "Model Engine Construction," published by Whittaker and Co., White Hart-court, Paternoster-square, E.C.

SUBSCRIBER.—Do not know anything more than is given in the article. The date would be a few days before that of the number in which the article appeared.

NAUTICUS.—From the Assistant Secretary, Burlington House, W. You can obtain all particulars about the Royal Astronomical Society and its publications.

J. J. J.—Pitch is the distance between the teeth; boss is another word for hub. Please see the back volumes, or any elementary work on mechanism.

A. ASTON.—See the article. A mere sketch would be waste of space in asking the writer to "supply dimensions."

CAROLAN.—See the almost innumerable replies about wiring dynamos.

B. LEIGH SMITH.—We do not know of any "economical" rotary engine in the ordinary sense of that term; but Parson's steam-turbine, which is a rotary engine (in terms), is a decided success.

J. B. P.—You will find many recipes of the kind desired by searching through the back volumes; but as to cheapness, that depends mainly on the quantities in which you can buy the ingredients. Obviously cheaper by the ton than by the pound.

SEMPER SURSUM.—Nothing better than bisulphide of carbon or benzol—not benzoline. Answered many times in back volumes.

COUPLER.—See the back numbers, or such a work as Mr. Stretton's "Safe Railway Working," published by Crosby Lockwood and Son, Stationers' Hall-court, E.C.

J. C. C.—We do not know, but probably, if published, by Macmillan and Co., St. Martin's-street, W.C. Why not ask the professor himself if the lectures are published?

T. A.—Can be obtained from the secretary of the Society of Arts, John-street, Adelphi, W.C.

A. DRYSDALE.—Tell him to try boracic acid rubbed all over the feet. It is a dry powder, and harmless.

THE Washington monument was struck by lightning on July 14, and the wires used for signalling to the lift conductor were burnt out.

IT is stated that the Japanese coal market still continues in a bad condition, and the accumulations of stock at Kyushu and the coalfields show no signs of diminishing. Prices are so low that shipments from Kyushu do not cover the expenses.

A NEW patent automatic ticket-recording machine, known as the Ohmer Fare Collector, has been brought under the notice of the Leeds Tramways Committee. The dimensions of the machine are 5¾in. by 1¾in. For every penny received the conductor is expected to strike the "recording plunger," which rings aloud the amount of money paid, and indicates it by figures displayed on an automatic wheel. At the same time the conductor should touch a lever which automatically prints and delivers a small paper ticket to the passenger, and exposes to view on another counting wheel the exact number of passengers carried. It is claimed that the machine does all the registering necessary, and that there is no need for an elaborate system of office checking.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent One Month before expiration, in order to give them time to forward fresh remittance before subscription expires.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. No reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No Displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch, single column—

1	6	13	26	52 insertions.
7s. 0d.	6s. 0d.	6s. 0d.	5s. 0d.	5s. 0d. each.

Per Column.—

1		13	26	52 insertions
£3 0s.	£2 15s.	£2 10s.	£2 5s.	£2 0s. each.

			13	26	52 insertions.
	£ s.	£ s.	£ s.	£ s.	£ s.
Per Page....	8 8	7 0	6 0	5 5	5 0 each.
Half-page ..	4 10	3 15	3 10	3 0	2 10 "
Quarter-page	2 10	2 5	2 0	1 15	1 10 "

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	s. d.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements must reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements except those in the Exchange and Sale Columns) may be addressed to "———," care of the English Mechanic Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to The Strand Newspaper Company, Limited, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

Special Notice. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

"English Mechanic," 517 numbers to date, clean and perfect. Offer wanted.—Schofield and Hilton, Diggle, Oldham.

Donkey Pump, cost £20. sacrifice £5, suitable for small yacht. 1H.P. Horizontal Engine, new, cheap.—Below.

Quantity of 1½ **Shafting,** Plummer Blocks and Pulleys. A Gents' Tandem Cycle, bargain, £5 5s.—Below.

Wanted, in **Exchange for Above,** small Vertical Launch Boiler, Propeller, Shafting, Sailing Boat.—Cooke, Mile End, Portsmouth.

Crystal Palace Pattern Polished Chain Box **Mangle,** new, cost £9. Exchange. Postcards refused.—Albert Blake, Portsea.

One-man power Bischoff **Gas-Engine,** in good working order, £4, or would exchange for good Drilling Machine.—Hart, 47, Godiva-street, Coventry.

Reflecting Galvanometer, Kelvin, under glass stand, magnificent instrument. What offers? or exchange value £10 cash. Letter.—O., 83, Burghley-road, Highgate-road, N.W.

Locomotive Model (working); length with tender, 5ft. 6in.; gauge, 5½in.; cost over £400; accept half, or part exchange musical; bargain; one of the grandest models ever built. Also rails, sleepers, and trucks. Photo. six stamps. Seen appointment. Letters only.—O., 83, Burghley-road, Highgate-road.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of **Screws, Bolts,** and Nuts for model work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—Morris Cohen, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—Clegg, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—Jarratt, Queen-street, Leicester.

Carving. — Brass, Iron, Burnt Wood, Bamboo, Leather, Fretwork, and Picture Framing. Catalogue free.—Harger, Settle, Yorks.

Inventions Protected, £2 inclusive. Designs registered, 30s.—Brookhead and Co., Registered Patent Agents, 33, Cannon-street, London. Established 25 years. Send for list.

Sidereal Time Indicator, invaluable to all users of equatorials, with complete directions, 21s. post free.—Below.

Astro-Photographic Apparatus, does really good work, 15s. post free.—Horne and Thornthwaite, 416, Strand, London.

Rubber Outer Covers, average 16ozs., Para rubber 5s. each.—Frankland.

Rubber Outer Covers, 3s. 6d. each, 36s. per dozen.—Frankland.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—Frankland.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—Frankland.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight., 2s. each.; 21s. per dozen.—Frankland.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 3s. 6d. each.—Frankland.

Detachable Outer Covers, licensed, 12s. 6d. each.—Frankland.

Saddles.—A clearing line in ladies' and gents' saddles, 2s. 6d. each, 24s. per dozen.—Frankland.

Inflators, 18in., 1s. 6d. each, 15s. dozen.—Frankland.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 5s. per dozen.—Frankland.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—Frankland.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—Frankland.

Spanners, nickel, usual price, 12s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—Frankland.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—Frankland, Astley Gate, Blackburn.

Books.—All out-of-print books speedily procured, any subject. State wants.—Baker's Great Bookshop, Birmingham.

Rubber Outer Covers, 8s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—Pemberton.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 3d.—Pemberton.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—Pemberton.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—Pemberton and Co., 1, Cardwell-place, Blackburn.

Acetylene.—Send for particulars of the patent "Incanto" Generators, Purifiers, Burners, Carbide, &c.—Thorn and Hoddle, 1, Tothill-street, Westminster. Works, Harris-street, Camberwell.

Photography.—Watkins' Actinometer makes exposure certain, new watch shape, 3s. 6d.—Fields, 142, Suffolk-street, Birmingham.

"Demon" Gas-Engines, Otto principle, awarded prize medal, guaranteed efficiency. All sizes from ⅛B.H.P. upwards.—Below.

"Demon" Gas-Engines, ½B.H.P., £9; ¾B.H.P., £12; 1B.H.P., £15; 1½B.H.P., £18; 2B.H.P., £23. Wonderful value.—Below.

"Demon" Gas and Oil-Engines, high-class, popular prices. Particulars free.—Pasley and Co., Sherborne, Dorset.

50,000 Choicest Microscopical Objects.—Bargains. Catalogues free. Microscopes, cabinets. Collections purchased.—Suter, 10, Highweek-road, Tottenham.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—Butler Bros., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—Butler.

"Spesco" Belting Syrup, prevents slipping and keeps belts in good condition, 1lb. sample tin, post free, one shilling. Spesco Ltd., Suffolk-place, Bermondsey, London.

W. Probert and Son, Brassfounders, Whateley-road, Handsworth, Birmingham.

Manufacture Brass Fittings in quantity to sample or drawing.

Brass Tubes, Sheet, Rods, Wire or Strip.

Brass Castings to Pattern.

W. Probert and Son, Whateley-road, Handsworth, Birmingham. Works: Tower-road, Aston.

Model Boiler, 13in. tubular, nearly new, tested 50lb., brass mountings, 17s.—51, Winchester-road, Romsey.

Simplex Typewriter, 14s. 6d., delivered. Thousands in use. Illustrated particulars free.—Atkinson and Co., Harehills-avenue, Leeds.

"B" Gas and Oil-Engines. Supplied the world over. Particulars stamp.—A. and S. Barker, Engineers, Leyton, E.

Launch Oil Engines a Speciality. New designs. High speed. Very reliable.—A. and S. Barker, Engineers, Leyton, E.

"B" Oil-Engine Castings and Forgings. Easy to make; no complicated parts; very reliable.—Barkers, Leyton.

"B" Oil and Gas-Engines are fitted with silent gears, sensitive governors, adjustable bearings.—Barkers, Leyton.

Original Testimonials can be seen at any time, together with English and Colonial Press opinions.—Barker.

Wheel-Cutting.—Spur, bevel, mitre, or spiral gear, in all metals, to any pitch.—Motogear, below.

Differential and Spur Gearing as illustrated in "E. M." Motor tricycles. Special prices.—Motogear, below.

Accurate Screwcutting and Fine Turning a speciality.—The Motogear Engineering Co., 78, Queen Victoria street, E.C.

"Gem" Gas-Engines.—Still simplest and best for small powers.—Motogear Co., below.

"Gem" Gas-Engine Castings. — Easiest to make up.—Motogear Engineering Co., 78, Queen Victoria-street, London.

"Gem" Oil-Engines.—New designs for launches and vehicles, &c.—Motogear Co., above.

Sample 100 Billheads, Memorandums, or Cards, post free, 1s. 3d.—Young, 57, Leyton Park-road, Leyton.

Watches, Clocks, Jewelry, Musical Boxes, Novelties. Dealers supplied at rockbottom trade prices for cash. Cheapest house in England. Lists on application. Gentleman's crystal face keyless nickel silver, 3s. 9d.; not less than three will be sent.—Woolrede and Co., 90, 91, Queen-street, London, E.C. Agents wanted. Mention Paper.

Paraffin Wickless Stoves burn without smoke or smell, safe and reliable, very useful in household.—Below.

Paraffin Wickless Stoves, powerful and easily managed, splendid thing for yachting, boating, camping-out.—Below.

Paraffin Blowlamps for Plumbers, Painters, Brazing, and Ignition Tubes. Illustrated lists, stamp.—Hicks, Tool Merchant, Maldon, Essex.

Register of all London and North-Western Locomotives, 6d. free.—Holland Co., Publishers, Cherry-street, Birmingham.

"Amateur Work," 8 vols., handsomely bound, bargain, 16s., cost 40s.—Holland Co., Book Merchants, Birmingham.

Lathe, back-gear, 9in. centres, face plate, and tools; double crank and 4 speeds, in perfect order, £8. Must sell.—31, Havil-street, Camberwell.

Gregorian, 4in., mounted with screw motions. Newtonian, 6in., focus 48in., complete.—1, Hadley-road, New Barnet.

Microscopical.—Diatoms mounted in highly refracting media, including realgar, styrax, &c. Prices reasonable. Approval.—Gatrell, Barnes.

6½in. Equatorial Reflector, Calver, massive iron stand, slow motion, three eyepieces. Sell, or exchange Refractor; room wanted.—Apply C., 172, Finchley-road, Hampstead.

Bench Lathe, complete, with 2 chucks, 14s. 6d., photo 6d.—Duck, 27, Lamb's Conduit-street, W.C.

Stereoscopic Views, 1s. doz., list 4,000. Sample 1d. stamp.—Pumphrey, Stanhope-street, Birmingham.

Motor Tricycle Fittings, Axles, Brackets, Heads. Latest French-pattern Axles, castings or finished. Illustrated list free.—F. Harding, Brixton Motor Works, 303, Brixton-road, London.

Motor Castings for Trike or Light Vehicles and Carriages.—Steer Motor Works, Redhill.

Pneumatic, 28 wheels, good tires £2; photo. 2d. "English Mechanic," 20 vols., 20s.—Moore, Photo., Oldbury.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, SEPTEMBER 1, 1899.

MOTOR CYCLES.—XV.

AT this stage of the work a general arrangement of the complete machine will be of assistance in understanding the uses and positions of the various parts which have been described in detail.

Fig. 95 shows the tricycle with the right-hand rear wheel removed. In making this show. The petrol is contained in the oval tank T, held to the back stays by clips. From the tank the petrol is led to the float-chamber by the copper pipe U. V is the screwed cap over the filling hole. To control the admission and vary the quality of the explosive mixture admitted to the combustion-chamber of the motor, two small levers are provided in a convenient position on the top tube. One of these appears at W; the other is precisely the same, but on the further side of the tube, and is therefore hidden. The lever which is seen is the one controlling the supply of pure air. The levers are coupled to the handles of the plug of mixing cock, and its air-regulating plate by light rods, the one shown, G′. This plug-switch is of great use in preventing any unauthorised person from riding off with the machine, or exhausting the batteries by turning on the handle-bar switch at a time when the cam on the motor-valve gear-sleeve is making contact with the contact-springs.

In building the frame of the machine, great care must be taken to insure every joint being sound, and the intending builder cannot do better than follow the clear directions recently given by "Derwent" in the ENGLISH MECHANIC. It would be waste of time for me to repeat them here, and nothing can be added to them; therefore I will confine myself to giving the dimen-

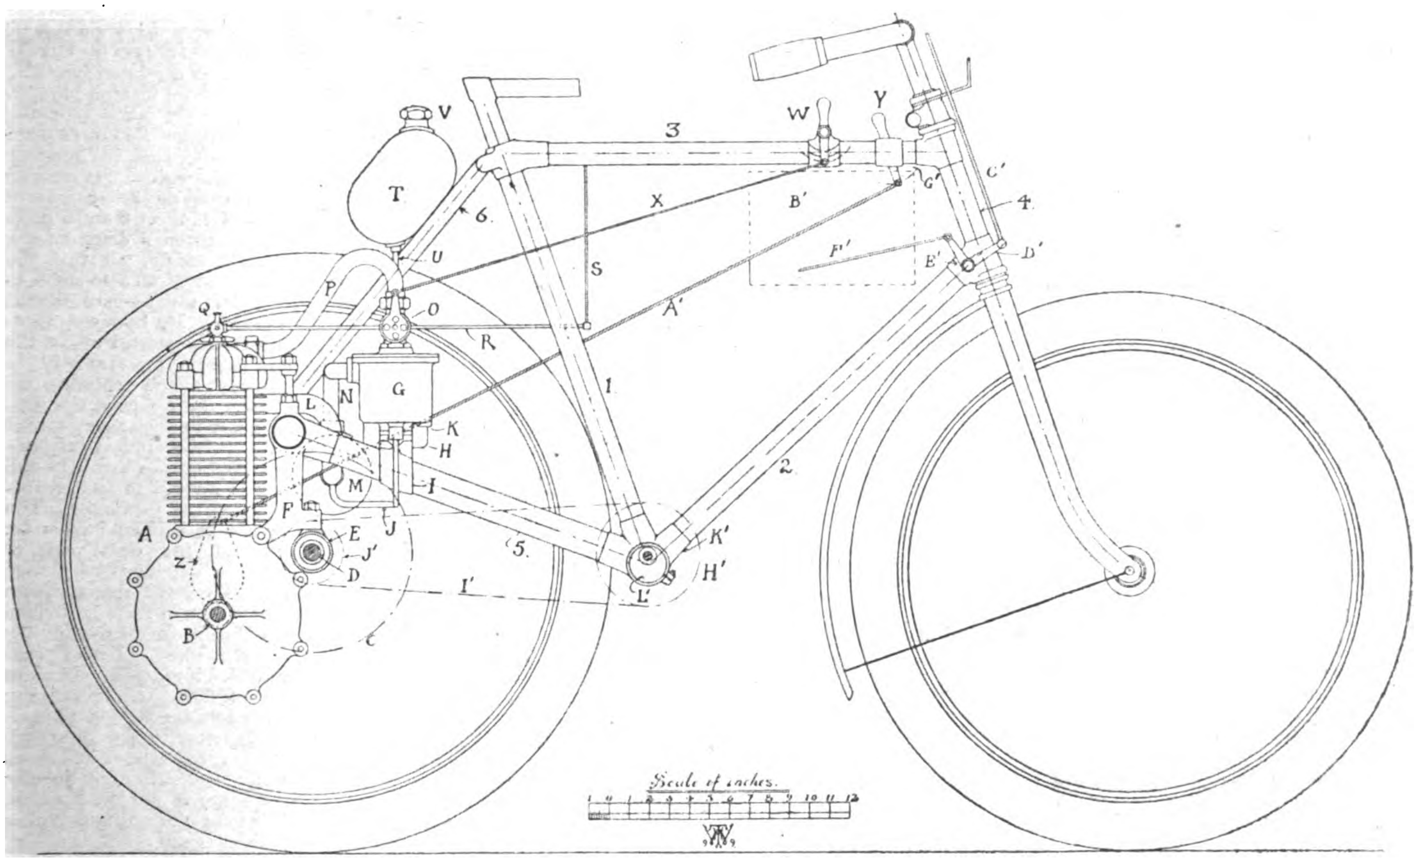

FIG. 95.

drawing I have been guided entirely by the dimensions given of each part, and, therefore, if the various components have been made to the sizes given they will come together correctly. The reference to the letters in Fig. 95 is as follows:—A is the motor complete, B the driving pinion, C the driving-wheel, D the axle, E one of the axle bearings, F the bridge tube and compression stay lug shown in detail in Fig. 56, G is the carburetter, H being the float-chamber behind it, I is the lug holding carburetter and float-chamber in place, for details of which see Fig. 88. The exhaust branch pipe is seen at J, and the outlet of the exhaust coil in the carburrertter at K; L is the exhaust pipe leading to the silencer M. The pipe which leads from the air heating chamber to the carburetter I have lettered N. O is the mixture regulating cock, and P the vapour pipe to motor; Q is the compression relief cock, to the plug of which is fastened the long rod R, which passes through, and is supported by, a lug brazed to the seat-tube, but not shown in Fig. 95. At the end of this rod, remote from the cock, is a lever connected by the vertical rod S to a handle, pivoted on a lug on the top tube, by means of which the rider can manipulate the compression-relief cock while seated in the saddle. As both lug and handle come behind the top tube in Fig. 95, they do not lettered X, being attached to the air-plate. There is one more handle on the top tube, seen at Y, the movements of which control the position of the sparking apparatus Z by the medium of the rod A′. The battery case is shown dotted at B′. It is suspended by two straps from the top tube, and steadied by another passing round the bottom tube, in much the same way that a luggage carrier is attached to the frame of a bicycle. The induction coil is slung from the bridge tube in the same manner as, but on the opposite side to, the exhaust silencer. We come now to the brake controlling gear. There will be two levers on the handle-bar, one on either side, neither of which appear in Fig. 95, as they would obscure the levers on the top tube. The lever on the *right* hand of handle-bar operates the band-brake on the back axle through the rod C′, which is adjustable, and attached to the bell-crank D′ by a ball-joint. This bell-crank is pivoted at E′ to the lower head lug, and, by means of the rod F′, is coupled to the upright rocking-shaft lever seen in Fig. 72. The lever on the *left* of handle-bar works a brake on the front tire in the ordinary manner, or one of the many rim-brakes or front-hub band-brakes now on the market. The handle-bar switch is contained in the *left*-hand handle-bar grip; the plug switch, used when the machine is left for any period without anyone to look after it, is placed at sions and gauges of the tubing to be employed. All the lengths are given from centre to centre, and due allowances must be made for mitring the tubes together. Liners should be used throughout, especially at the junctions of the steering tube and forks with the crown plates. The tubes are numbered in Fig. 95, thus:—1. Seat column, 1¼in. diameter by 18 gauge; length from centre of bottom bracket to *top* of seat-lug, 22¼in. 2. Bottom tube, 1¼in. diameter, 18 gauge; length from centre of bottom bracket to centre of steering socket, 22¾in. 3. Top tube, 1in. diameter, 18 gauge; length from centre of seat-column to centre of steering socket, 22in. 4. Steering socket, 1¼in. diameter, 18 gauge; length from centre of top tube to centre of bottom tube, 5½in. 5. Compression stay-tube, 1⅛in. diameter, 18 gauge; length from centre of bottom bracket to centre of bridge-tube, 19in. The length of the two back-stays (6) will be best determined after the rest of the frame has been built. They are intended to be ⅞in. in diameter, 18 gauge, round tube, though D or oval tubing may be used at the discretion of the builder, but round tubing is the strongest. Whichever section be employed, eyes, formed from steel stampings, are to be brazed into each end, and drilled to take the seat-pillar, bolt at one end, and the ⅜in. bolts at the other ends, by means of which they are clamped to the bridge tube lug (Fig. 54). These

eyes must be "set" so that they lie close to their places without strain when the bolts are tightened up. The front forks are to be especially strong, of best weldless steel tube brazed into a three-plate crown. Forks such as are used for triplets and quads will be suitable, and if they can be obtained 1¾in. by 16 gauge so much the better—they cannot be too strong. A tandem or triplet hub will do for the front wheel drilled for 40 No. 13 gauge spokes. The steering pillar, brazed to fork crown, should also be very strong, 1⅛in. diameter by ⁵/₃₂in. thick will be right. At the top end it can be turned down and screwed to fit closely into the handle-bar, clip, and adjusting-nut; but be sure in turning it not to leave a shoulder, but taper it gradually from the thicker to the thinner parts. In the journals devoted to cycling there is advertised a form of tube which has much to recommend it. I refer to a patent seamless drawn tube with thickened ends, which requires no liners, and as liners are always troublesome to fit and involve heating the tube twice, which adds to the risk of burning, I advise the employment of the butted tube.

The remaining references to Fig. 95 are:—H', sprocket-wheel; I', chain; J', sprocket-pinion; K', bottom bracket; L', bottom bracket eccentric.

The mixture pipe leading from carburetter to motor, and the hot-air pipe to carburetter, I shall not give drawings of, as these are best bent and fitted after the parts they belong to are fixed in position. The hot-air pipe is to be of copper, ¾in. inside diameter by 18 or 20 gauge, and the vapour pipe of the same material and gauge, but ⅝in. inside diameter. This latter has a cone for union (Fig. 30) brazed to each end, and see that the union nuts (Fig. 30) are slipped over the pipe before brazing the second cone on. The hot-air pipe is brazed into the socket (Fig. 38) on air-heating chamber, the other end having a flange brazed on ⁵/₁₆in. thick, and of the shape and size given in Fig. 39. The float chamber is connected to the petrol tank by a copper pipe, ¼in. outside diameter by about ³/₁₆in. bore. There is a cock and union immediately below the petrol tank to allow the pipe to be disconnected when there is petrol in the tank. Details of the petrol tank, regulating levers, and a diagram of the electric circuits will form the subject of the next article.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—II.

It is not everyone who possesses the mechanical dexterity necessary for repairing a barometer when it gets out of order; and indeed, in the long run, it is better to return a faulty instrument to the maker thereof. There are, however, certain adventurous individuals who will attack the difficult manipulations connected with mending and overhauling a barometer, and since such operations at least lead to a better understanding of the principles on which the instrument is constructed, they are not altogether to be deprecated. In any examination of a barometer the first question which arises is as to the quality of the mercury in the tube. The mercury used in the construction of a barometer should be as pure as it is possible to make it, and it is commonly necessary to free it from such intruding substances as lead, iron, and sulphur, since traces of these are often to be found in it. These impurities are driven out by treating the mercury with diluted acetic or sulphuric acid, and it is then fit for use. A simple test to discover whether the mercury is suitable for putting in a barometer tube, consists in dropping a little of it in a thermometer tube of a very small bore, which has been exhausted of air. If the mercury then freely runs up and down this constricted tube it will probably rise and fall easily in any barometer tube no matter what the diameter of the latter may be. Moreover, mercury is at all times liable to collect minute air-bubbles, and search should be made for these with the aid of a lens, and if it then appears bright it may be considered satisfactory. As already mentioned, the cisterns of some barometers need to be raised or lowered when reading the instrument, and if after making the reading the cistern be lowered, the mercury will be depressed out of reach of intruding dust, and its surface will be kept bright and untarnished.

Of all the vitiating circumstances likely to interfere with the working of a barometer there is none so difficult to detect as the presence of air in the tube. It is in handling and moving the instrument that air is most likely to enter, and although with some barometers its expulsion is not a very difficult matter, it may easily be overlooked. When once air has found its way into the tube it gradually pushes its way upwards until it enters the Torricellian vacuum at the top of the column, and since the air has tension or pressure it prevents the mercury from rising as high as it otherwise would do, and the readings of the instrument are accordingly below the truth. Similarly, moisture or a little vapour of mercury may find its way up the tube and destroy the perfectness of the vacuum. The presence of moisture is always to be suspected when the mercury appears to cling to the sides of the tube and renders the movements of the column sluggish. A common way to determine whether there is air in the tube is to incline the latter so that the mercury may strike the end of it, a sharp click indicating that the vacuum is perfect, while a dull sound denotes that air has collected and formed a cushion. Seeing, however, that the column of mercury has considerable weight, it will be realised that this is a test which needs to be applied cautiously, for too great a momentum will result in a broken tube. When filling a barometer tube for the first time moisture and air are driven out by boiling the mercury in the tube itself over a charcoal fire. Bubbles of air are sometimes easily expelled by slowly depressing the tube so that they travel upwards to the cistern and so escape, refractory bubbles being hastened upwards by very gently tapping the end of the tube on one's foot.

Seeing that there are so many accidents to which a barometer is liable, it is always desirable to spend a little time in seeing that it is properly hung in position, and so protected that it cannot be knocked by passers-by. Two bars of wood about 18in. long, 6in. wide, and 1½in. thick may be fixed along the wall, one being about 5½ft. from the ground and the other 2ft. These two bars should be perfectly horizontal, the face of the lower one being in exactly the same vertical plane as the upper. To these bars, which should be firmly fixed in position, a cage or wire box may be attached in such a way as to inclose the two wooden bars, and one particular kind of cage is made wedge-shaped, so that the two doors or flaps open right out. This, for many reasons, is a better arrangement than a four-sided cage, for with this latter form much of the light is cut off from the barometer, and its indications are not readily seen. In places where the barometer is likely to be knocked by children, or in public buildings where many people pass, some such protecting cage as the above, which is very easy of construction, will be found to protect the instrument from damage. The barometer is, of course, hung by means of a bracket fixed to the upper board, and it is recommended that the bracket be put not in the middle of it, but at one side; so that if at any time it is desired to hang another barometer alongside for purposes of comparison, room may be available for it.

When tilting a barometer for the purpose of expelling air it cannot fail to be noticed that the more it is inclined the higher up the tube the mercury travels, and from this observation it may be concluded that to obtain a correct reading it is important that the barometer be hung truly vertical. Any departure from the vertical makes the reading too high, and, accordingly, when hanging a barometer it is necessary to put it on the bracket which carries it in such a way that it swings quite freely, and after the true vertical has been found by a plumb-line the lower part of the barometer may be fixed in position. Moreover, since the mercury in the barometer contracts and expands with alterations in its temperature, a correction is necessary for this change in the length of the column, and it is for this purpose that all good barometers have an attached thermometer. But this correction is one which requires a reference to correction tables, and although this is a highly important operation in scientific meteorology, it may be supposed that this is a matter with which the ordinary individual does not concern himself.

To reduce this correction for temperature as much as possible, it is necessary to keep the barometer in a part of the house where it will not be subject to great extremes of temperature, and to this end it should be kept away from the direct rays of the sun, and placed also where no heat can reach it from hot-water pipes or from a fire. The north side of a house is commonly the best quarter in which to find a spot where temperature is most equable, and it is well also to remember that, like an invalid, a barometer is very susceptible to draughts. Further, when a barometer is hung in such a way that the top of the mercurial column is above the line of sight, the recorded readings will always be too high, for the scale and the top of the mercury do not coincide. Accuracy of reading is therefore secured by hanging the barometer so that the meniscus or top of the column is on a level with the observer's eye. These are methods of procedure which do not call for a very large amount of work; but their observance always results in adding to the efficiency of the barometric records.

When once it is understood that changes in the weather do not depend so much upon the height at which the barometer stands as upon the rate at which it rises or falls, the first step is taken towards getting the best results from its indications. Now, there is no better way of showing these risings and fallings than by plotting the barometer readings on a diagram, and so produce a curve. Commonly, all that the unprofessional meteorologist is able to do is to read his barometer twice a day—once in the morning and the evening. If, however, these two readings be plotted as suggested above, the daily march of atmospheric pressure will be shown far better than by simply entering the records in a note-book. Such curves are produced by ruling a diagram in such a way that it may be divided horizontally into thirty-one spaces—one for each day of the month;—and vertically the diagram is divided so as to represent the scale readings of the barometer. The horizontal spaces should be half an inch wide, and if they be divided into four equal parts, as many as four readings a day may be plotted without confusion. The vertical spaces should be one inch high, and if each of them be divided into ten, there is no difficulty in discovering the correct position for each entry. Ten of these vertical spaces thus divided into tenths will allow of any reading between 28in. and 31in. being plotted. When the barometer is read twice a day it is quite easy, therefore, by plotting each entry in the form of a dot, to put each individual reading in its correct place. Then, by joining the dots by a line, a curve is produced which, day by day, clearly shows the changes taking place in the atmospheric pressure.

As already mentioned, when using barometer readings for strictly scientific purposes, it is necessary to correct them for temperature, and if also it be desired to compare the readings with those taken at neighbouring stations, it becomes necessary to reduce them to some common standard or height. Any height might be taken; but it is the common practice to reduce all barometers to the level of the sea—or, in other words, they are made what they would have been had they all been taken at this level. Supposing, therefore, that the observations are made at an altitude of 500ft., there may be considered to be a column of air between the point of observation and the sea-level; and the necessary correction for altitude resolves itself into discovering the weight or pressure of this column of air. Further, since this column of air changes in weight with every alteration in temperature, it is necessary to know the temperature of the air before the amount of the correction can be properly determined. It will, however, be seen that at a station having a Continental situation it is a fiction to speak of a column of air being between the station and the sea-level, and only when the observer is in a balloon floating over the sea can this column of air be strictly considered to be present. However, it is the weight of this fictitious column of air expressed in barometric inches that forms the correction which an observer needs to add to his barometer readings when he desires to reduce them to the mean sea-level. Moreover, since it is impossible to determine the average temperature of this column of air, what is done is to take the temperature at the point of observation, which is, after all, but the temperature of the top of the column of air between the observer and the level of the sea. It will be gathered, therefore, that in reducing

Occultations of (and a near approach to) Fixed Stars by the Moon, visible at Greenwich.

barometer readings to the mean sea-level there are many considerations which tend to complicate the question, and while the results obtained by this method commonly adopted may serve for the purposes of comparing one station with another, the barometer readings thus reduced cannot be taken as absolute values.

Tables giving these corrections for reduction to sea-level are given in many meteorological publications; but similarly to the correction for changes in the temperature of the mercurial column, it is to be feared that most people when consulting their barometer ignore the fact that they may be a considerable height above the level of the sea. Seeing, however, that a knowledge of this height is so desirable, it is well for anyone who wishes to render his meteorological operations useful to inquire for the nearest bench-mark and discover what is the approximate height of his locality. Newspapers nowadays give barometer readings for many different towns, and are often the only available source of meteorological information for isolated observers; but since these readings have probably been reduced to mean sea-level, it is important that anyone comparing their barometer with these reports should apply a similar correction. Roughly speaking, one-tenth of an inch is added for every 100ft. of altitude, so that an observer 250ft. above the sea should add ·25in. to all his barometer readings when comparing them with those taken at other localities. By managing one's barometer in accordance with the foregoing suggestions, which represent the minimum of care demanded by all barometers, it wi l be found to respond to the orderly and systematic method of treatment, and the way will be prepared for using it in larger meteorological enterprises.

ASTRONOMICAL NOTES FOR SEPTEMBER, 1899.

The method of finding the Sidereal Time at Local Mean Noon at any other station is described on p. 454 of Vol. LXVIII.

Exhausted apparently by the recrudescence of disturbance some time since, the Sun is now apparently quite quiescent, and the period of minimum sunspots may at last be held to have arrived.

At 6h. 29m. 37s. a.m. on September 23rd the sun is said technically to enter Libra, and Autumn is supposed to commence. This, as has been explained here, signifies the *sign* and not the constellation Libra; for, as a matter of fact, he is at that instant in Virgo, at the obtuse angle of a very obtuse-angled triangle, whereof β and η Virginis are at the extremities of the base. This is the theoretical date of the equinox, but actually in London it is not until the 25th that the Sun will be just twelve hours above the horizon and twelve hours below it.

During the latter part of the month the Zodiacal light may be looked for in the east before sunrise.

Mercury

is a morning star throughout September, attaining his greatest elongation west of the sun (18° 2′) at 7 a.m. on the 5th. He may be caught before sunrise early in the month with an opera-glass, but scarcely now with the naked eye. His angular diameter diminishes from 8·2″ on the 1st to 4·8″ by the 3rd.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	9 34·9	13 22·4	10 53·4 a.m.
6	9 52·2	13 19·0	10 50 9 ,,
11	10 19 5	11 48·8	10 58·5 ,,
16	10 52·2	9 5·8	11 11·5 ,,
21	11 26·5	5 36·6	11 26·0 ,,
26	12 0·1	1 46·0	11 39 9 ,,

Mercury will thus travel from Leo into Virgo. On the morning of the 8th he will be a few minutes to the north of Regulus, and visible in the same low-power field of view as that star.

Venus

is a morning star too at the beginning of the month, but comes into superior conjunction with the sun at 8 a.m. on the 16th, and, of course, afterwards travels to the east of him. Her angular diameter does not vary from 9·8″ from the 1st to the 30th, and her disc is, of course, for all practical purposes, circular. As, however, she will be, in effect, behind the sun during the greater part of September, this can scarcely affect the observer.

Day of Month.	Right Ascension.	Declination.	Souths.
	h. m.	° ′	h. m.
1	10 28·5	11 1·9 N.	11 46·8 a.m.
6	10 51·9	8 44 9 ,,	11 50·5 ,,
11	11 15·1	6 21·9 ,,	11 54·0 ,,
16	11 33·5	4 24·1 ,,	11 57·2 ,,
21	12 0·9	1 23·7 ,,	0 0·3 p.m.
26	12 23·6	1 8·5 S.	0 3·3 ,,

Starting thus from a point to the N.E. of the 4th mag. star ρ Leonis, Venus will cross into Virgo, and be found at the end of the month to the south and east of γ Virginis.

Mars

has left us until the beginning of 1901.

Jupiter

is too near to the sun to be fairly visible, an observation which is equally applicable to

Saturn,

who is too low down for observation when it becomes sufficiently dark. This is equally true of

Uranus;

and

Neptune,

who comes into quadrature with the sun at 5h. a.m. on the 20th, scarcely rises soon enough. Thus the night sky, as far as the planets are concerned, is a perfect blank.

* Early morning of the 2nd.

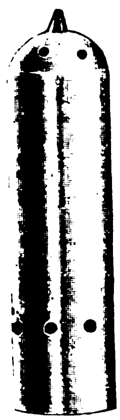
The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list on any other night in August, as also of determining the Local Instant of its transit over the Meridian of any other station, will be found on p. 456 of Vol. LXVIII.

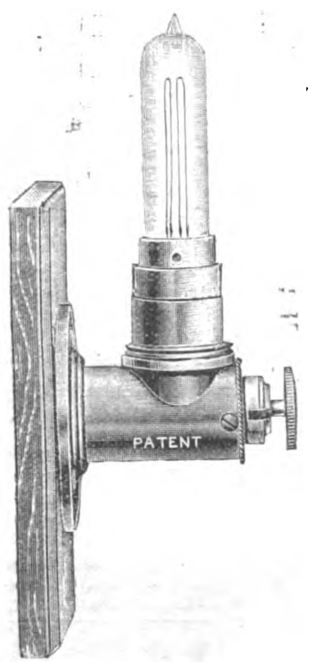
Shooting Stars

are neither very numerous nor conspicuous in September. They are predicted for the 4th, 5th, 10th, 15th, 21st, 22nd, and 27th.

SEGNITZ'S PATENT ELECTRIC LIGHT REDUCING APPARATUS.

THE apparatus shown in the accompanying illustration has been designed specially for the purpose of reducing the lighting power of incandescent electric lamps. The apparatus is





extremely simple, and is made of brass or other metal, and consists of a suitably constructed lamp-holder and switch. The lamp-holder is made to fit the usual size of bayonet-socket incandescent lamps, and for this purpose tubular lamps of various resistances are used. One wire of the light circuit which it is desired to reduce is cut away in any suitable place, and the two ends are connected to terminals inside the apparatus. By means of the switch these two terminals can be bridged at will. Thus it will readily be seen that the lamp of the apparatus can be placed in or out of series with the lighting lamp, and consequently the light reduced, or put on full at will. By using lamps of different resistances in this apparatus one or more incandescent lamps may be reduced in power to any desired degree fixed upon, and, moreover, if it is desired to change a lamp, say, of 16c.p. which was being reduced to 2c.p. for one of 32c.p., and yet reduce the light to 2c.p., it can readily be done by simply placing a different-sized lamp in the holder of the reducing apparatus. There is absolutely no danger from fire, as the greatest heat produced is never more than the hand can bear, and it is well ventilated. When the light is reduced with this apparatus, the electricity consumed is less in proportion to the amount of reduction. A metal shield, as shown in the illustration, is made to fit over the tubular lamp for protection, but may be taken off with ease if desired.

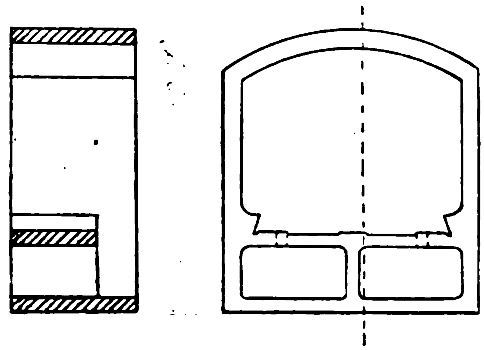


FIG. 41.

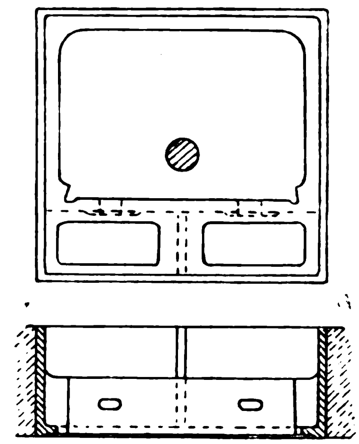

FIG. 42.

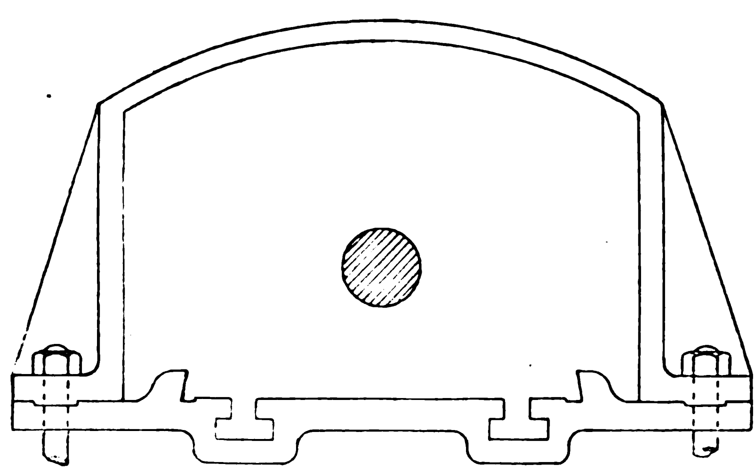

FIG. 43.

MILLWRIGHT'S WORK.—VII.

WALL-BOXES are employed in several forms, as in Figs. 41-3. They carry plummer-blocks when shafts have to be brought through from one department to another. Their outlines vary in a considerable degree. The commonest form is shown in Fig. 41, being a plain square box which is built into the wall. The widths of boxes bear some standard relation to the size of pedestal, and do not always coincide with the thickness of masonry in the wall. The width of the plate upon which the plummer-block is bolted is less than that of the outer frame of the box. It is raised above the bottom to permit of the insertion of the hold-down bolts. Usually joggles are cast at the sides, as in base-plates, to permit, in conjunction with the slot-holes, of lateral adjustment, and of wedging. If vertical adjustment is necessary, it must be done by wood packing between the block and its base-plate. The top of the frame is flat in small boxes. In large ones it is generally arched, for increased strength.

A stronger type of box is shown in Fig. 42, being stiffened with a narrow flange on one face. Such castings have to be produced at a very low price, and even the addition of a flange increases cost of moulding. If, therefore, a flange is cast, it should be reduced to a mere narrow rib or fillet.

A neat wall-box, made by Robert Poole and Son, of Baltimore, U.S.A., is shown in Fig. 43. It is made in two parts, bolted together with four bolts. Instead of casting a plate above the bottom to receive the foot of the pedestal, tee-grooves are cast, so that the bolts can be slid in from the front.

Wall-boxes take the common pedestals, or the swivelling ones of any type—those which swivel

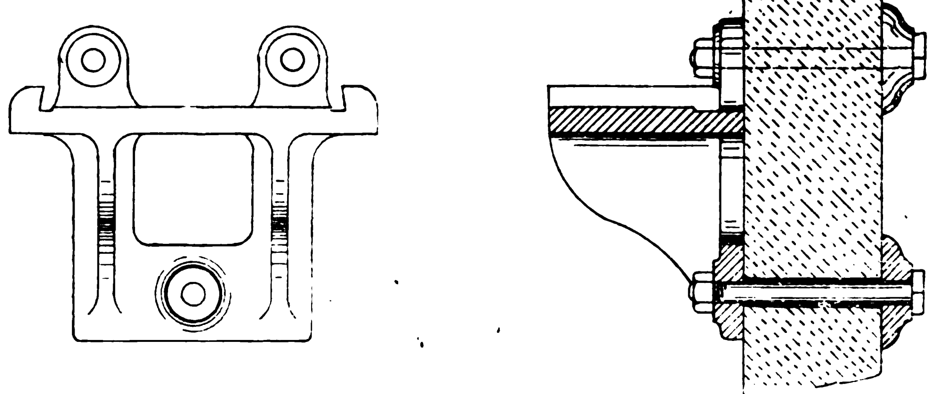

FIG. 44.

sideways only, or those which can also be adjusted in a vertical direction.

End-plates carry plummer-blocks when a shaft comes up close to a wall without passing through it, and when there is no means of attaching wall-brackets adjacent, or pillar brackets. The forms of end-plates are mostly similar to those shown in Fig. 44. The pedestal is bolted to the plate,

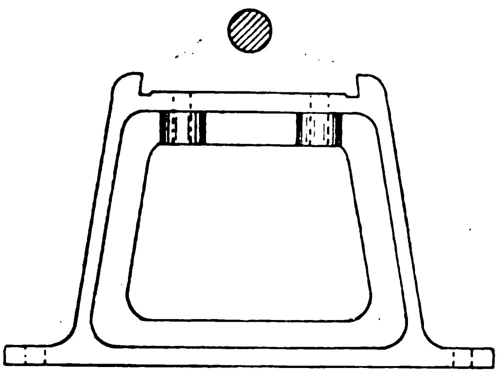

FIG. 45.

adjusted with end wedges, and the back-plate is bolted to the wall with three through-bolts and broad washers.

There are two methods of arranging line shafts —one under or on the floor, the other under the ceiling. One of the largest examples of the first, or underneath the floor, which the writer has seen is at Crewe Railway Works, in the joiners' shop, where the wood-working machinery is driven without a shaft being visible. This arrangement is a matter in which, though, opinion and practice vary; the general consensus favours overhead shafting. There are several reasons for this. In favour of underground shafting there is the absence of belts coming down from above, which cause some amount of risk, unless they are fenced in, which is an inconvenient arrangement in the case of machine tools at least. But the room which is occupied by the belts could not be utilised for any other purposes; so there is little in this point. Another, and perhaps the best reason for the

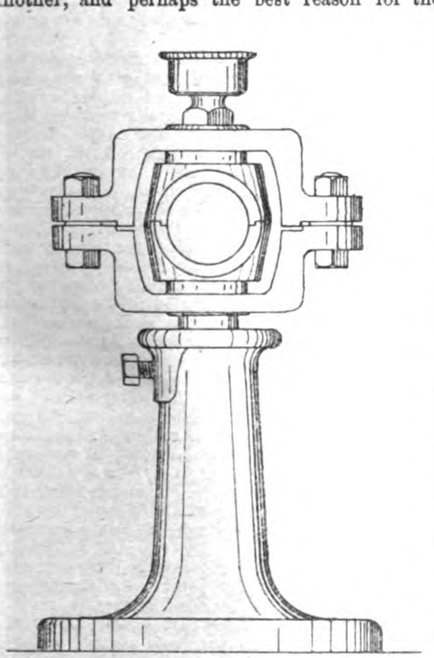

FIG. 46.

employment of underground line shafting, is that, being fixed on rigid foundations, much less care is necessary in attendance to those details of fitting which are necessary in shafting which is suspended from a roof. The shafts in a pit may be heavier, bearings more rigid, and couplings of the massive, solid type, without affecting results, excepting in so far as absorption of power is concerned—a detail too often overlooked, and upon which no check is made.

Against the underground shafting the risk of fire must be discounted. Everyone knows how accumulations of dust and grease in a factory increase risk of spontaneous combustion, and a pit affords a receptacle for accumulations of dust carried down by the belts or falling through the floor. Then the expense of brick-lined pits must be added to that of the shafting and fittings.

The conditions most favourable to the use of underground line shafting are those in which the shafts are exceptionally large and heavy, such as is required in driving a large shop of wood-working machinery, and when the joists overhead are not sufficiently rigid to support its weight. In ordinary cases, engineers give preference to the overhead method of driving.

Speaking generally, the same class of pedestals, so far as bearing arrangements are concerned, are used for floor as for top shafting; but stands are used in the first case to carry the pedestals (Fig. 45). They are bolted down to timber or stone, and the top forms a sole-plate for the plummer-block, which is packed with wood and wedged and bolted in place. For light shafting, the type of bearing, Fig. 46, of the Unbreakable Pulley Co., is more suitable. It is light, occupies little room, and the bearing is adjustable vertically by slackening the set screw and raising or lowering the bearing portion in the base, and it can swivel universally. J. H.

NOTICES OF BOOKS.

The Steam-Engine and Gas and Oil-Engines. By JOHN PERRY, D.Sc., F.R.S. London: Macmillan and Co.

ON the title-page of this work there is a sentence which is rather sarcastic, although it may not be intended; but it reads, "A book for the use of students who have time to make experiments and calculations." Surely all students have time to study their work, or where does the student come in? However, Prof. Perry has had much experience, and knows what he is talking about. He says:—"Readers have great faith. Tell them that some philosopher obtained a certain law of adiabatic expansion of steam, and they use that law, never testing it for themselves, although the test may only need half an hour's work. Tell them that there is a method used by everybody for showing the wetness of the steam in a cylinder, on the indicator diagram, and they use that method, although the exercise of a little common sense would show them that the method is based on a fallacious assumption." That gives the keynote of the work, which may be commended to the attention of all students who wish to master the subject of their study, and it applies to all branches of science. "Try it yourself," is the teaching of Prof. Perry, and his aim is to show students how they may themselves attack problems, and perchance solve them. Even if they fail, the work done will assuredly give them a better grasp of the real nature of the problems than if they had accepted the statements made in the books, and had never attempted to verify the "figures"—a term which, in this case, includes everything. When a pound of average coal is carefully burnt and all the available heat is measured, it gives out about 11,700 Fahr. heat-units (8,500 Centigrade), and that is equivalent to 12,000,000ft.-lb. A pound of kerosene gives 17,000,000ft.-lb., and a cubic foot of average coal-tar gives 530,000ft.-lb. at atmospheric pressure and 0° C. (32° Fahr.) Then, remembering also that 33,000ft.-lb. per minute equal 1H.P., we have the data for proceeding with the study of the subject. Prof. Perry says "it is very easy to measure with more or less accuracy the true pressure of steam on the piston of an engine by means of an indicator, and from this to calculate the indicated power. But the power actually given out by the engine is less than this; hence a man who sells engines is not so anxious to talk of this brake-power, the power actually given out, which might be measured by a brake or any other form of dynamometer." The volume is well supplied with illustrations, and there are many exercises (with answers); but the real purpose of the work is to inculcate the principle that to learn a subject thoroughly it is necessary to do something more than merely read books. The reader or student of this work will need to have some acquaintance with mathematical formulæ; but it will be worth his while to acquire the requisite knowledge in order to understand the author.

The Management of Small Engineering Workshops. By ARTHUR H. BARKER, B.A., B.Sc., Wh.Sc. Manchester: The Technical Publishing Co., Ltd.

IT might be supposed that in these days there can be no need for such a work as this; but those who have made a study of the subjects are well aware that much money is wasted in small workshops under the system of management adopted. It would be more correct to say—owing to the absence of any system. The smaller engineering workshops are, as a rule, badly managed. So-called "economies" are practised which turn out to be very expensive mistakes. As the author of this work says, "Good works management consists of two elements—(1) Promptly supply to the shop both the material to work on and precise and unmistakable instructions as to what is to be done with it; and (2) Seeing that the work ordered is properly and quietly done. Broadly speaking, the first is the province of the manager himself; the second, that of the foreman. It is a sign of bad management somewhere when these are not efficiently done, and where the people in the works have to do any of the first, or the manager any of the second." Enormous amounts of money may be wasted in working both worn or inaccurate tools, and no wise manager or foreman will tolerate them for a day longer than is absolutely necessary, is a truism well known; but it will bear repeating, for there are still many shops in which old tools are "made to do," sometimes with difficulty, but always with a loss of economy. There is much sound advice in this work, and the proprietors of small shops, as well as their managers, may derive much benefit from a perusal of its pages.

Ajax Loquitur. By ROBERT WEATHERBURN, M.I.M.E. London: Crosby Lockwood and Son.

THIS is a work which will have a certain amount of interest and charm for all who like to read about the history of the locomotive and its technical details. "Ajax," otherwise known as the Old No. 9, being doomed to the scrap-heap, tells the story of his construction and his life—in other words, he writes his autobiography. "Ajax" says he is the child of Invention and Experiment, and proceeds to trace briefly the history of steam-engines and locomotives; but being rather old, his memory is not always trustworthy, and he seems to have forgotten some of his ancestors. However, he says "Watts and Newcomen demonstrated the power of vaporised water, and showed the value of reciprocative action; and then another ancestor, named Catch-me-who-can, was made a raree-show of by one Trevethick, on a circular track at Bunhill-fields." That probably refers to the locomotive exhibited, by Vivian and Trevithick in a field near where Euston Station now stands. "Ajax," it appears, was "matured in Lancashire," under the direction of one of the best men of the day, who was so pleased that he labelled the engine with his own name. Having introduced himself and given an account of his family history, "Ajax" proceeds to talk about cylinders, motions, pumps, injectors, &c., and in his way conveys a great deal of information about the details of locomotives, which will certainly be found read b'e by all, and interesting to those who would like to get an idea of the progress of the locomotive. The volume is freely illustrated, and there are two excellent portraits of George Stephenson (frontispiece) and his son Robert.

Portland Cement. By D. B. BUTLER. London: E. and F. N. Spon, Ltd.

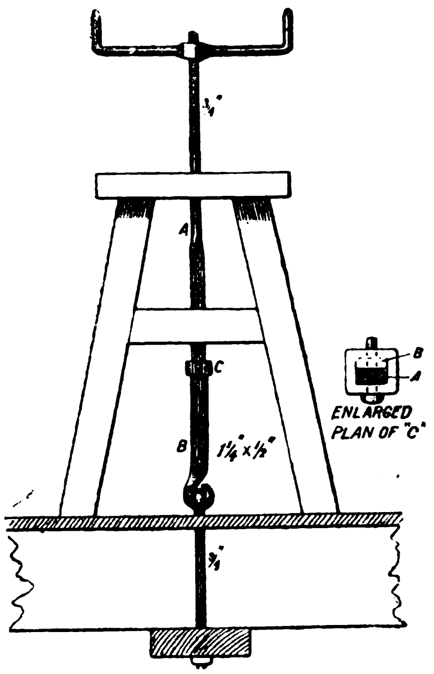
PORTLAND cement is so valuable a material in connection with the arts of construction from the builder's point of view, that any work on its manufacture is sure to meet with attention. Smeaton years ago made elaborate experiments on cements and the methods of preparing them; but it need scarcely be said that great improvements have been made since his time. The earlier experimenters in the manufacture were, as the author says, afraid of pushing the calcination too far, and therefore did not arrive at the present degree of perfection, which still leaves room for improvement. Portland cement is one of the few industries which originated in this country, but as suitable materials were found in other countries the trade soon ceased to be a monopoly, although this country still holds a leading place for quality if not for quantity. Portland cement from the chemical point of view consists mainly of lime and silica, with varying proportions of

alumina, iron oxide, and some other substances, the most important of which is probably sulphuric anhydride; but the quality of the cement depends to a very great extent on the processes employed in the manufacture. The principal raw materials used in its manufacture are the chalk and estuary muds found in great abundance in the lower reaches of the Thames, especially near the mouth of the Medway. These are dried and ground very finely and calcined; but the manufacture has of late years become almost a fine art, requiring the attention of the chemist to analyse the raw materials, and so to direct the proportions in which they should be mixed to obtain the best results. In this work full details of the manufacture are given with illustrations of the plant employed, and in the section on the "use" of Portland cement the importance of having it properly matured is dwelt upon, for the cement is really a rather "tricky" material. It must not be too new or fresh—that is fatal—and it must not be too old; it is imperatively necessary that all surfaces should be clean, and that loam or other "dirt" does not mix with the cement. Mr. Butler's work is the latest on the subject, and contains all the information available up to date. It may be that one result of its publication will be to increase the number of cement works, for there are other places than the estuary of the Thames in which so-called Portland cement can be made, if a few experiments are tried.

We have also received *The Maintenance of Solar Energy*, by An F.R.A.S. (London: The Southern Publishing Company, Ltd.), which consists of preliminary notes on the evolution and devolution of the Solar System. It is a work that will interest many, especially solar physicists, for the author says, "If the sun is heated matter, increasing in heat in the deepest portions, why, when the deeper parts are exposed to view, as in the spots, do we not find it more luminous below?" The author thinks the photosphere to be by far the hottest portion. Those who study Selenography and Areography will find something to interest them in this little volume.——*Metal-Plate Work*, by C. T. Millis, M.I.Mech.E. (London: E. and F. N. Spon, Ltd.) is the third edition, considerably enlarged, of a work which has become a standard textbook for students, and those who have to shape metal plates into useful articles.——*The Merchant's Handbook*, by W. A. Brown, M.A., LL.D. (London: Edward Stanford) is the fifth edition of a well-known work on money, weights, and measures of the nations with their British equivalents. It has been brought up to date and is a standard work of reference in connection with moneys, weights, and measures.——*A First Book in Statics and Dynamics*, by Rev. J. L. Robinson, M.A. (London: Longmans, Green, and Co.), is a textbook for those who are preparing for the matriculation of the London University, and for those who are reading for the elementary stages at South Kensington. It is well adapted for its purpose, as the examples are clearly set forth, and beginners will find much help from them.——*The Arithmetic of Electrical Measurements*, by W. R. P. Hobbs, R.N. (London: Thomas Murby), is the seventh edition of a useful work for those who wish to learn all about electrical measurements in practice. There are numerous examples worked out, and those who carefully follow will find no difficulty in fully comprehending all about electrical measurements.——*Pocket-book of Useful Formulæ and Memoranda*, by Sir Guilford L. Molesworth and Henry Bridges Molesworth (London: E. and F. N. Spon, Ltd.), is the twenty-fourth edition of a well-known and widely appreciated pocket-book for engineers and workers all the world over. The electrical portion has been thoroughly revised and brought up to date.

A STAND FOR HOLDING WHEELS TO BE FILLED.

THE following plan is contributed to the *Blacksmith and Wheelwright* by Mr. J. Vestal, Walnut Hill, Arkansas, who says:—Take a piece of iron ¾in. round, about 2ft. 10in. long. Cut threads on it 10in. on one end, and flatten the other end about 16in., and punch ⅜in. hole in it every 2in., as far as the flat part goes. Then take another piece, ½in. by 1¼in., 12in. long, turn an eye on one end of it, B, and then make a cuff, C, out of the same size iron, 1¼in. square, slip cuff over the piece A, ½in. by 1¼in. at end, and weld to one side of cuff. Then drill a ⅜in. hole through cuff piece you weld to, so as the flat part of the ¾in. round piece will slip through. Take another piece ¾in., any length wanted, turn an eye on one end, thread the other, and put this piece through the floor with eye on top of floor; then hook the flat piece with cuff on to it, then run the flat end of the round piece through the cuff, and put a ⅜in. pin through the hole in cuff. Make a tap to tighten down with on top. Have two handles to tap or nut, then build around it anything to hold up wheel, and by using the above you can fit every length hub, and only use one block to



do it. It can be adjusted underneath in one minute's time. My stand is made like that shown in the inclosed sketch.

THE PREPARATION AND MOUNTING OF WOOD SECTIONS.

I COMMENCE this paper with the full realisation that, by the side of highly specialised laboratory methods, I am writing in a very humble sphere, but I offer no apology. It is to be remembered that there is a great deal of valuable microscopical study that is not done in laboratories, and by those who have not the time or means for elaborate methods, nor is it to be forgotten that well-prepared vegetable sections hold a large place in educational work.

The first thing required for successful section-cutting is a good microtome; no matter how cheap, or by whom made, so long as it does its work well. It is not everyone that can train his nerves and muscles to cut free-hand sections of any size and uniformity of thickness. Good section-cutting means a knife of the finest steel, and the finest edge; the wake of "saw teeth" in an imperfectly sharpened knife never looks well in a wood section, and this sharpening of a knife is something that does not come of itself, it requires practice. No edge thin enough for fine sectioning will stand hard wood unsoftened, and I have found nothing quite as good for this purpose as boiling for a short time, or soaking for two or three days in a strong solution of pearline; it softens without destroying any part of the tissue.

For imbedding use hard paraffin, especially in the summer; it shrinks less, holds the object more firmly, and the edges of material imbedded are less likely to tear. If the paraffin rolls, as it most likely will, press it lightly with the ball of the finger as the knife goes through it—no danger of sectioning the finger.

Next in importance is the right thickness of the section, which should be governed entirely by the object to be attained by observation, and not by the exercise of mechanical genius in cutting as thin as possible. Hard and compact tissue, like most of the woods, requires to be cut very thin, while objects like Pteres aquilina, root or stem, with large fibro-vascular bundles, require to be cut thicker to preserve the structure complete, and the section entire. This holds true especially of longitudinal sections. After cutting a few sections, examine with the microscope and vary the thickness, if necessary, till the desired result is reached; time spent in this way is time saved. It makes a difference whether the section is to be mounted in balsam or some other medium, as will be seen hereafter.

If transparency is desired, most sections require to be bleached before staining. A good rule is to bleach till the chlorophyll disappears, or the colour from the wood is discharged, and no longer. If bleached too little, the sections will be disfigured with dark blotches; if bleached too much, the section will go to pieces, or its character will be destroyed. The bleaching fluid must be well soaked out, in repeated changes of pure water, or staining will be a failure.

The primary object of staining, single or double, is not for beauty, but for use, and yet a beautiful slide is not to be despised on that account. Slides are educators, and the education of the sense of beauty is no barrier to scientific research, and it is quite possible that in some cases it may be an inspiration. It requires but little skill to so stain a wood section as to bring out stunning colours, but that is not staining in any high sense of the word. Staining means such use of colours as to differentiate structure for accurate observation. And let me here say that there are no line-drawn rules of universal application; it is largely an empirical art, and the best results, as a rule, are wrought out by careful and intelligent experimenting, and my aim is to offer a few simple and general rules which may serve as guides in lines of work within limited means and opportunities.

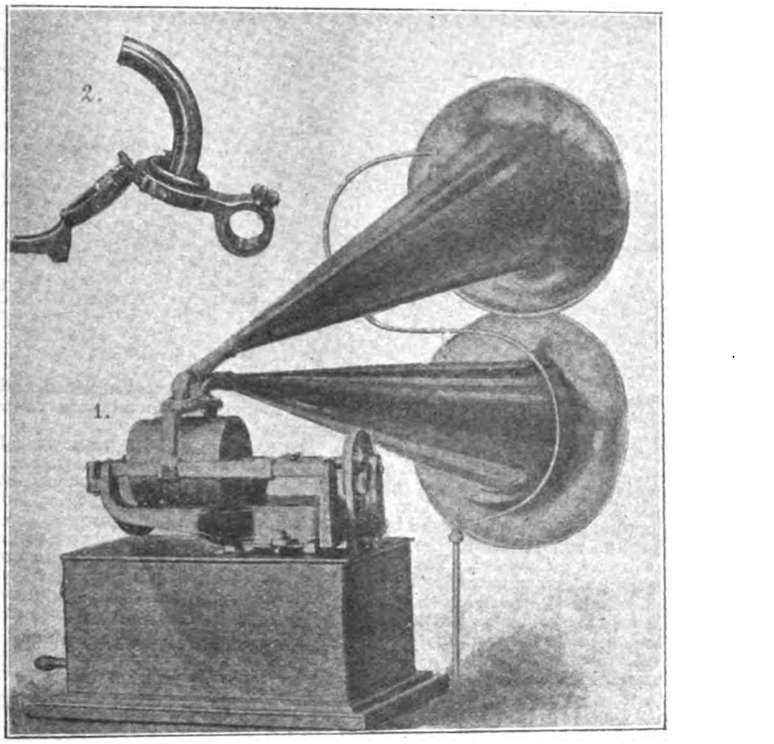
Reagents.—There is a long list of reagents in use, all of more or less value, but I mention a few only, with their use, which will be found most effective in the line of work before us; and I will preface this part of the subject by mentioning a single condition without which success is impossible, and that is cleanliness. No dish, or glass, or instrument should ever be used without cleaning the last thing before using. Water, whether distilled or not, should be filtered, and all staining fluids will bear to be watched, and filtered as often as the least impurity appears.

For staining cell walls there is nothing superior to Delafield's hæmatoxylin, but nine-tenths of the staining done with this reagent is so deep as to render the object opaque and comparatively worthless. This fluid should be diluted with the purest water obtainable till the colour is a very little deeper than that sought in the object, and allowed to stain slowly, or the section should have a very brief immersion in full-strength fluid — always rinsing in water. Hæmatoxylin has a delicate reaction, is permanent, and when properly used nothing is better for many things, if quite as good; but when unskilfully done, no staining is worse.

Bismarck brown is a very valuable, but, as far as my observation goes, a very much neglected stain. It is somewhat opaque, and therefore not adapted to compact tissue, but where lace-like structure, or large spiral or scalariform vessels are to be shown, it has no equal. In combined, compact, and loose structure, it has all the striking and brilliant effect of double-staining. Use the same methods as with hæmatoxylin.

The easiest and most effective double-staining is done with red and green, and of these colours Grenacher's borax carmine, and methyl, or anilin green, will be found most generally reliable. Borax carmine is more properly an animal stain, but it is of the highest value in botanical work, when it plays its part in double stain. It requires time, and does not colour deeply, but it is transparent, and can be made deep enough for all practical purposes if the following method is followed:—First place the section in borax carmine for twelve hours or more, as found necessary; wash rapidly, yet thoroughly, in 50 per cent. alcohol; place for two or three seconds in a saturated solution of any of the anilin greens, preferably anilin or methyl; wash as before, and return to borax carmine till the red reappears, changing the borax carmine after the superfluous green is driven out. As soon as the outlines of the colours are distinctly marked, and secondary tints disappear, rinse as before, and place for a few moments in alum cochineal; this acts as a mordant to the borax carmine without destroying its transparency. This process, like any other, is liable to failure by over-doing or under-doing some part of it, but when successfully followed the result will be all that can be desired. It may seem superfluous to call attention to the chemical relations of reagents; but in years of teaching I have found it necessary to guard this point with special care. Hæmatoxylin and alcohol must be kept separate, or you will have more mud than colour, and rinsing borax carmine with 95 per cent. alcohol will ruin everything by precipitation.

Mounting Media.—Which is the best—glycerine, glycerine jelly, or balsam? We will dispose of glycerine by counting it out entirely; it gives the poorest definition of all, and, however well sealed, cells are liable to leak from expansion of the fluid by heat. The comparative merits of balsam and glycerine jelly are best determined by experiment. Balsam has three faults which render it objectionable where the fine details of structure are to be preserved. It shrinks protoplasm, and the process of dehydrating for mounting, distorts delicate tissue, and the medium makes it worse. Its tendency is to make everything transparent, and sometimes so transparent as to be worthless. There is an acid in balsam that is an enemy to colour. The chemist that will furnish a neutral balsam will be a bene-



factor. Balsam has its merits, and is indispensable where the object is in itself opaque, or when outline definition mainly is wanted. It is easy to use, and the objection of transparency may be in part overcome by cutting the section thicker or staining deeper.

For mounting in balsam, dehydrate by passing quite rapidly through 50, 70, and 95 per cent. alcohol to absolute, and clear in oil of cloves, or in xylol, which is better, if xylol balsam—which is to be preferred—is used.

Personally, I prefer glycerine jelly to all other media for general use; it preserves structure and colour best, and gives a character of honesty to the slide. Kaiser's formula is best as far as it goes, but, to stand summer heat, more gelatin should be used than the formula calls for, and it should be carefully and faithfully filtered. It is not as easily used as balsam, but little difficulty will be experienced if the following directions are followed:—

Work in a warm room.

Heat, and keep hot while using, in a water-bath.

Mount from chemically pure glycerine and 95 per cent. alcohol, one volume of each, kept till perfectly homogeneous, and filtered.

Warm the slide, and place the jelly on it with a glass rod, kept clean.

Place the object in the jelly, being sure that it is well covered. This may require an additional drop.

Hold the object in place and drain the slide to get rid of the glycerine and alcohol.

Cover the object again with jelly, and examine carefully under the dissecting microscope for air-bubbles, especially for *stowaways*. Air-bubbles should be worked off with a dissecting needle and not picked out with the forceps.

Cover the object again, take the cover-glass between the thumb and finger, breathe on it, cover it well with jelly, take it by the edge with the forceps, turn it over quickly, place it gently on the object at an angle, and apply a clip.

If it is desirable to mount more than one object on a slide, place them in just jelly enough to cover them safely from air, and give time to harden, after which an additional layer may be added, and the cover placed as before, and held with a clip. Next pass the slide over a spirit lamp, till the entire mass of jelly is melted. If the right quantity has been used, the objects will not slide out, or if they become displaced, push them back again with a slip of pointed paper slightly moistened in the mouth. If the glycerine jelly becomes too thick by repeated heating, or from other cause, add a small quantity of filtered water.—J. D. KING, Ph. D., Cottage City, Mass., in the *Journal of Applied Microscopy*, N.Y.

THE "POLYPHONE" ATTACHMENT FOR PHONOGRAPHS.

ONE of the simplest, and at the same time one of the most ingenious, attachments for talking-machines which has yet appeared, is found in the "polyphone," a phonograph sold by the Talking-Machine Company, of 107, Madison-street, Chicago, Ill. It has long been a well-known acoustic principle that when a sound has been reflected or repeated within an exceedingly short interval of time, the original and the repetition sound in unison. The makers of stringed musical instruments apply this principle by using sounding-boards, upon the resonance of which the quality of the tone depends. In the "polyphone" a similar principle is employed.

The "polyphone" is fitted with two diaphragms and two styli, arranged one in front of the other, so that the same sound is twice produced. At first blush it might appear that one diaphragm would reproduce one word and the second another word. But when it is considered that the cylinder makes two revolutions in a single second, it is evident that the interval between the two sounds is so small that the repetition and the original practically coincide. Since the repeated sound is equal in volume to the initial sound, it follows that the "polyphone" is capable of reproducing a word with twice the loudness of the ordinary phonograph. In addition to this increased volume, the use of two diaphragms imparts to the sound that quality which, as before remarked, depends upon the application of the principle of resonance, or of repetition. The double diaphragm can be applied to any phonograph whatever, so that any ordinary talking-machine can be converted into a polyphone.—*Scientific American*.

PRODUCING STRAIGHT CASTINGS: METHODS OF STRAIGHTENING.*

TO be thoroughly equipped for handling all the crooking castings that come to a jobbing foundry requires a clear understanding of the causes by which warps are produced, and the several devices for correcting them—that is, it should be known beforehand what the crooks will be, and the proper treatment for each case. Straightening by bending the pattern in the sand in an opposite direction is one of the most simple methods, and easy to understand; but it is only applicable to a very limited number of cases, such as long, slender lathe-beds, where the pattern has only moderate stiffness to overcome.

By Stripping.—The lintel-box, Fig. 1, is a good sample of a crooking casting, and one easily treated, as it has the heavy side on top. I have handled very successfully all sizes up to 40ft. long. and weighing nearly 5 tons. Although the long sizes have lately been largely superseded by the more reliable made-up steel article, these still serve to illustrate one straightening treatment. A 12ft. lintel of this form would have a top-plate, as moulded, say 1½in. thickness, the sides ⅞in., tapered down for draught to ½in. at the bottom. Such a casting would cool very irregularly as to time. The top side, when the cope was removed, would be a bright red, while the thin edges at the bottom would be a very dull red, and the casting still straight. Such a combination, with irregular shrinkage to follow, would promise a crooked casting—that is, the top side, having the most shrinkage to occur, would become too short, and would be concave a half-inch or more, or contrary to mere shrinkage set. It presents a simple case. The metal has been distorted by shrinking irregularly under confinement, and the remedy lies in stretching the top side by stripping two or three sections near the middle, or about 5ft. of its length altogether. Cooling the top, if it cannot lift the ends, is a stretching process on the top plate. Weighting down the ends would be harmless in this case, and might be needed, as a lift of the ends would defeat the stretching of the top plate.

By Heating.—An 8in. fluted building column, 12ft. long, which, on account of the anchor blades being too thin, had sunk into the loam core, allowing the core to rise, and which promised a crooked casting, was treated thus:—The top was stripped nearly bare, and 100lb. of cold melted iron poured, a little at a time, all over the top, then all was well covered with sand. On examining it later the colour of top and bottom was found about equal, and the casting in the morning proved to be straight—a

Fig. 1

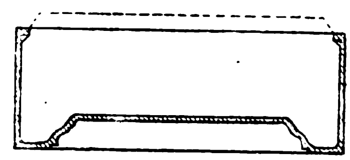


Fig. 2

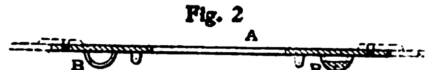

Fig. 3

more valuable quality in a column than perfect equality of metal; and this treatment reduced the permanent shrinkage strain by insuring an equal time of cooling. With a stiff cast "barrel," the core, at the exact centre, probably raised ¼in., leaving ¾in. on top and 1in. on bottom, instead of ⅞in. all round.

By Bending, while Hot, in the Sand.—There are a few cases of long, slender castings showing objectionable warp, on account of unequal cooling, where the warp can be corrected very easily, and with more certainty than by any other process, by simply bending the flask in an opposite direction from the warp. The bend should be made soon after pouring, or while the metal is still a high red, so that it will yield easily, and receive the true set without fracture. My first experiment with this device was on stationary engine-beds, the casting forming one side of a bed for 16in. and 18in. cylinders, with 4ft. stroke, and used quite extensively for driving Louisiana sugar-mills. They were of the bold-panelled ogee-moulding style, 20in. wide, 8in. deep, and 22ft. long. Fig. 2 presents a section cut through one of the four panels. They were cast with the face down, as shown, the inside being formed of green-sand cores hung in the cope, with two screws in the wrought-iron core skeleton, the pattern being solid. The dotted lines show the core-print guides for setting the cores, which were hoisted to place on the bottom of the core-box. With green-sand cores there will be considerable strain, a thickening at the bottom, which will increase the warp. These warped according to rule—that is, the ends sprung down 1¾in. Soon after pouring I set a heavy bar of iron under the bottom board, 2ft. or 3ft. from the end of the flask; then hooking on two sling hooks, hoisted the flask end until the end batten showed a lift of fully 1¾in. from its bed. Plenty of large wedges were then driven under several of the battens for a firm support. The crane was then taken off, and the other end of flask was treated in the same way. The flask in this case was of iron, but being long, and relatively slender, it bent under its weight with a very regular curve, producing a very true casting every way. These engine-bed castings, thus treated, averaged between 36 and 50 a year for a long term of years, and not costing a cent for treatment, the device proved valuable.

By Reheating.—These bed castings had formerly been straightened by the machinists who fitted them, under the direction of a very incompetent manager, by reheating with a wood fire and weighting down. They blundered in many ways, and obtained an imperfect job in every attempt. They persisted, against repeated advice, in resting the casing on one centre bearing, and in heating a very short section only, compelling a few inches of the length of it to stand an excessive amount of stretching, and almost invariably starting perceptible cracks, and kinking the top edges by excessive compression—that is, the top edge, as moulded, but the bottom when straightened. There is no excuse for committing such violence on a few inches of length when we have 22ft. to act on,

* By R. D. MOORE, in the *American Machinist*.

and worn-out flasks to slaughter. Besides, the longer the bend, the nearer the curved line is converted into a straight line.

Straightening by fire will be found to be one of the most delicate and difficult feats for the manipulator of castings. One of the most universal faults observed is the habit of piling on an excessive load of weight before heating, thus often cracking the casting before the highest heat is reached; the weight necessary is often surprisingly small. After witnessing many of those imperfect jobs, I volunteered to try one, and succeeded well in the following manner:—The bed was placed on two bearings, about 4ft. apart and 4in. high. A rough wall of firebrick or double grate-bars was made, 8in. or 10in. from the casting, to check the draught and the escape of heat, also to confine the fire closer to the casting. A strong wood fire was then applied to fully 5ft. of the middle of the casting. Gauge-blocks were set under each end to bend the casting to; but they were not final, as they should be adjusted when the bend is made. The heating may have raised or lowered the ends, and then the bend given would be out to that amount. To prevent the long ends from settling too soon, when heated, a lever was placed under each end, and a bar or plank to sustain one-third to one-half of the projecting weight until the time came to adjust the gauges and weight down. Such levers, carefully poised, will accommodate themselves to the heat bends, and not distort the casting beforehand.

I once had a very interesting experience in straightening the centre or column pieces of fire-fronts used on Western steamboats. The castings were plates about 26in. wide, 42in. long, by ⅝in. thick. Such a form has none of the crooking elements; but the manager thought it too plain, and he punted up a 4in. column pattern, not in use, and nailed the two halves on the front of the pattern, coring them with a half core, as shown in Fig. 3, which represents a section, split through a door opening at A, the dotted lines showing the adjoining overlapping plates, three plates constituting one boiler-front. The columns were only ¾in. thick, and cast on one side of a ⅞in. plate, made a combination very favourable for a crooked casting. The manager was duly warned of this tendency; but he only replied with a sneer. As one might have reasonably expected, those short plates warped ½in.—that is, they came out hollow, or concave, on the side opposite the column. They were, of course, required to be nearly straight, to match the adjoining plates. A few of the best were stretched with a hammer; but they were mainly so crooked as to require bending when red-hot. The fitters made some attempts at straightening with fire, but generally failed; they piled nearly a ton of pigs on each end before lighting the fire. After the fire had weakened the casting, it settled under its load, and, not being soft enough to properly bend, it broke, and was condemned. I finally offered to experiment, and with success, in the following manner:—After the casting was set, eight light pigs were placed on one end and three pigs on the other end. The casting was then heated up to a good red, then pigs were added until it settled to the bearings. Six light pigs on each end were found sufficient, showing that the former practice was overloading, three or four to one, and ruining good castings, mainly by that error.

Not having the time to spare for treating five or six castings for every boat we were building, I adopted another trick, which removed that trouble for the year following. I, "on the sly," fitted a board in the bottom of the column core-box, which added enough metal, out of sight, to make the shrinkage even and the casting straight. The added metal is shown at B B, Fig. 3.

PECULIAR TAP AND A FREAK COLLAR BUTTON.

THE following notes by Mr. H. J. Clegg, of Providence, Rhode Island, will interest many readers besides those who regularly study the *American Machinist*. The writer says: In the trades allied to the jewelry business occasional call is made for tools to fit altogether different conditions from the usual machine-shop practice. The main factor in this different order of things is, of course, the higher price of the materials, and scrap-saving devices are of more importance, as a general thing, than the reduction of time and labour usually sought in other shops.

The tap shown in Fig. 1 is one of these contrivances. It is intended to put a 36 thread through a 5/16in. hole. The bushings tapped with it are, when finished, ½in. long, and are the largest that we use in this class of work, most of the taps being for smaller bores, and having correspondingly greater numbers of threads to the inch. The part at *a* is thinned down to 3/32in. after being threaded in the usual manner, the diameter of the shank at *b* being somewhat less than the bottom of the thread. At *d* the teeth are given a radial face, and at *c* several teeth are brought down and backed off taper. The The shank at *b* is cut away for ½in., brazed on to

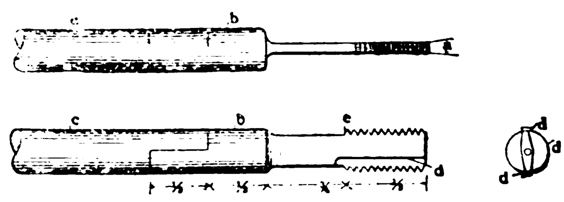

Fig. 1

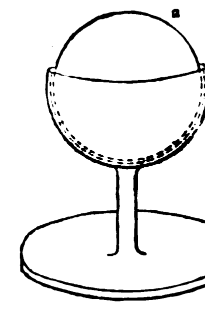

Fig. 2

the steel rod *c*, and then the tap is hardened and tempered. Although the tap is intended to cut a right-hand thread, it is backed off and relieved as if it were left-handed, or, rather, is made to cut backward, the cutting teeth being at *e* instead of at the end. The rod *c* is usually 3ft. long. The tubing to be tapped (about the same length) is slid on to *c*, which is then gripped in the chuck of a speed lathe. On starting the lathe to run backward, the tube is drawn over the tap and off the rod. The tube is held from rotating by a few turns of overlapping belt lacing passed around it, one end of the lacing fastened to a file held in the hand. The tubing is then cut up in the desired lengths by a thin slitting saw, wax being used for a lubricant.

A few taps cut with three grooves did not work anywhere near so well, would not stand the speed, and were apt to clog up with chips. I have talked the matter over with others who have had similar experience, and who pronounce this the best way of making a tap for this particular job—i.e., tapping drawn tubing in lengths.

This running a right-hand tap backwards reminds me of that (presumably) machine-shop fiction about the inventor who made a successful pump out of an unsuccessful rotary engine. It is to be hoped it is true, if only to prove how one may get the best of a very bad job. Be that as it may, an inventor came my way not long ago with a notion, and this inventor has made a unique application of a well-known mechanical device. The inventor's opinion of the thing it is unnecessary to quote. To put it mildly, he was enthusiastic; but I have not yet fully made up my mind whether the scheme will be a blessing or a curse.

Anyway, there it is in Fig. 2, a ball-bearing collar-button. The ball *a*, about 3/32in. diam., is nicely beaded, with a burnishing tool, either in press or by hand, into the belcher setting at *b*, and is free to turn loosely in any direction. I suppose an ordinary point-setting (or claw-setting used with diamond work) would do just as well if made heavy enough to retain the ball and not bind. Aside from the novelty of the thing, it is claimed that it can be pushed through the most obstinate shirt with an ease and readiness akin to the action of "greased lightning."

Have the fellows who have talked about the slippery collar-button these many years, in prose and poetry, earned their money honestly or not? It is said that all men are liars, but have not the shirt-waisted folks chimed in with the aforesaid opinions; and what shall be said of an attempt, based upon an everyday mechanical device of known character, to increase these baleful qualities of the collar-button that have caused so much annoyance?

JOINTS IN STEAM-PIPES.

THE increasing pressures which are met in modern steam plants have rendered necessary a review of the accepted proportions of pipe-flanges, valve bodies, and similar connecting elements, and an important study of the effects of pressure upon existing designs of these members has recently been made by Prof. C. Bach, and published in the *Zeitschrift des Vereines deutscher Ingenieure*.

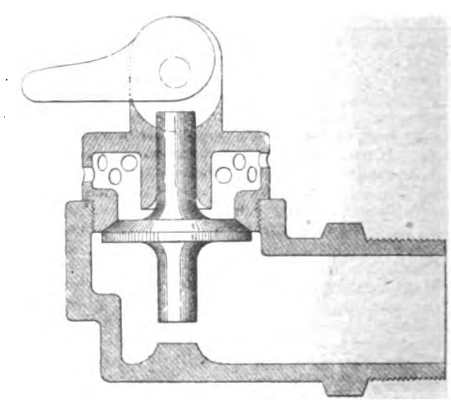
Every mechanic knows that it is one thing to make a flange-joint which shall be strong enough to resist breakage, and quite another thing to insure that it shall be tight against leakage under all the trying conditions of continuous service. Much of the trouble in connection with leakage lies in the fact that flange connections, whether on pipes or on valve bodies or fittings, are not stiff enough to resist deformation when subjected to high pressures. Realising this fact, Prof. Bach has conducted a series of experiments in which contact points were so arranged that the deformation under pressure of the various important parts could be accurately measured, and thus he obtained data as to the weakness of existing designs, so far as deformation is concerned, which no rupture tests could furnish.

By comparing these deformation tests with the actual strength and elasticity of the material, as indicated by trials in the testing-machine, the nature and magnitude of the fibre stress in various portions of the tested pieces was obtained, and thus a check upon theoretical computations of resistance was secured.

The tests were made upon wrought-iron pipes, and upon valve-bodies of cast iron, cast steel, and bronze, and the data thus obtained are tabulated in a manner which renders them available for use in connection with future designs. The whole subject of steam connections should be revised, in view of the changed conditions which modern practice has brought about, and makers of valves and fittings for such service might well conduct some such tests upon their own account, in order to be insured of the correctness of the proportions adopted by them.

STEAM-CHEST RELIEF-VALVE.

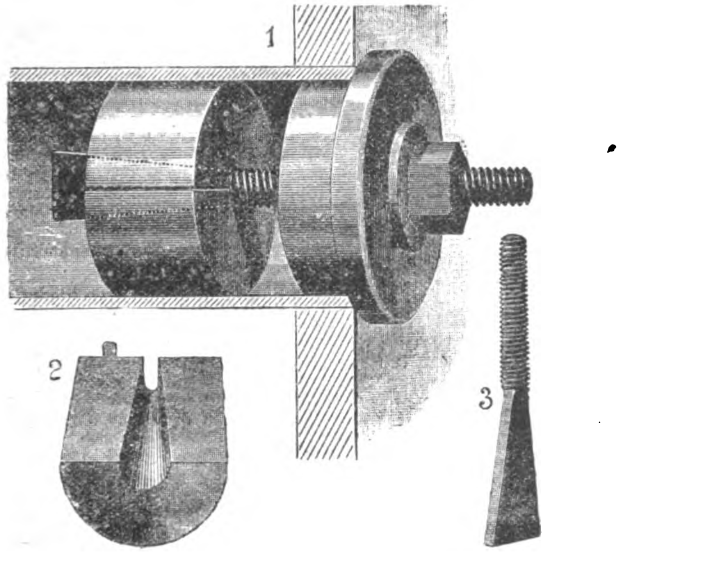
THE Norfolk and Western people make a relief-valve with a cam attachment which can be turned over when the engine is standing where they do not wish it to be moved, and the relief-valve will be held open. In case the throttle leaks, or the cylinder cocks are shut, the valve cannot work shut. This is convenient when standing on the cinder-pit, or at any place where the engine does not have



someone on or about her, as the amount of steam coming out of the relief-valve will call attention at once. The cam when turned over holds the valve off its seat in the same manner that the Sellers injector cam operates the overflow valve. The cut makes this matter plain.—*Locomotive Engineering*, N.Y.

PYROCATECHIN.

THE *Photographische Mittheilungen* again draws attention to this developer, which is closely related to hydroquinone. As it can now be manufactured chemically pure at a low price, and excellent formulæ for its use have been devised, it will probably take an important place amongst developers. It is often complained that fresh solutions of hydroquinone are prone to fog the plate. Pyrocatechin is free from this defect, and, whether fresh or several months old, yields negatives of great purity. Another advantage is that the image develops regularly and with rapidity. When the image has attained full strength, there is still some latitude, as it retains its character without risk of fog if the plate is left a little longer in the developer. This is more particularly the case with the pyrocatechin-phosphate formula (see the *British Journal of Photography*, May 6, 1898, p. 296), and the pyrocatechin-caustic soda formula as follows:—Solution 1: Sulphate of soda, 25 grammes; distilled water, 250c.c.; pyrocatechin, 5 grammes. Solution 2: Pure caustic soda, 3 grammes; water, 250c.c. For use take one part each of 1 and 2, and two to six parts of water. If the formula for combined development and fixation is used, the characteristics of the plate and the exposure must be taken into consideration. Although there is some latitude even with the com-



bined development and fixation formula, it is desirable to modify the formula for over or under-exposure. In the case of marked under-exposure it would be desirable to add more alkali to the developer, in order to obtain sufficient density.—*The British Journal of Photography.*

A RACE WITH THE SUN.

IN these days of quick travelling on land and water it is interesting to calculate some of the ways in which man could alter Nature's laws (according to the *Daily Mail*) for his own convenience by means of enormous speed. Imagine an aërial machine capable of travelling at any rate up to 1,000 miles an hour. A traveller in such a machine moving in a direction from east to west could, by making his speed equal to that of the earth's rotation, view the countries and seas of the world in perpetual daylight.

Suppose our imaginary traveller started from London at 10 a.m. at a speed of 660 miles an hour. As long as he kept that up he would be able to arrest the progress of time. To him it would always be 10 a.m. If he were travelling in the latitude of the Shetland Islands a speed of only 510 miles an hour would be necessary, whereas at the equator he would have to travel at over 1,000 miles an hour. Should he find unending day monotonous, he could reverse his direction, in which case he would have a quick succession of short days and nights of some six hours duration; but the length he could regulate by the speed of his machine.

Then suppose he started from London one night at 10 o'clock and travelled in a westerly direction at a speed of about 1,000 miles an hour. He would, as it were, overtake the earth, and would presently experience the extraordinary sensation of seeing the sun rising in the west, where it had set a short time before, and eventually setting in the east. In fact, the day would be reversed, and time, as we measure it, would be going backwards. If he stopped his machine he would have his day over again; but this time the right order of things would prevail, and the sun would travel in its wonted direction across the sky. The upsetting of another of Nature's laws might prove disastrous. Sound is known to travel with a velocity of 750 miles an hour, so that a warning whistle on board a machine travelling at anything like this rate would be utterly useless. A machine travelling at some 900 miles an hour would be rapidly overtaking its own sound, and anywhere in front the sound of its approach would be absolutely inaudible. In the event of a collision the warning whistle would be heard some time after the accident.

FLEMING'S FLUE-STOPPER.

The flue-stopper shown in the engravings annexed has been patented by Mr. J. W. Fleming, of Brooklyn, N.Y., and its construction will be readily understood, for Fig. 1 shows it in operation, Fig. 2 shows the body of the stopper in section, and Fig. 3 shows the key or expander which brings the "stopper" into action.

The stopper-body is constructed in two sections, each of which, as shown in Fig. 2, is formed with a groove, whose tapering side walls and inclined bottom wall deepen its contracted end. The channel formed by the registering grooves is adapted to receive a key (Fig. 3), having a wedge-shaped inner part and an outer, threaded, cylindrical part. Before the body-sections are brought together, the wedge portion of the key and a part of the threaded cylindrical portion are placed in the groove of one of the sections, so that the wedge can expand the sections.

When the stopper-body has been properly placed within the tube, the threaded part of the key extends through a cap having a body which enters the flue, and which is provided with a flange formed with a peripheral groove to receive the end of the flue. A lock-nut is carried by the threaded portion of the key, and has a bearing on the cap. By turning the lock-nut the stopper-body sections are expanded, and at the same time the cap is tightly forced against the inner edge of the flue.

THE RELATIONS OF PHYSICS AND ASTRONOMY TO THE DEVELOPMENT OF THE MECHANIC ARTS.*

(*Continued from p.* 34.)

VI.—Science Stimulates the Mechanical Arts.

THE demand for measurements of the highest attainable accuracy is characteristic of the study of astronomy and physics, and always keeps in excess, or, more properly, in advance, of the current state of the art of construction. Consequently, the needs of science have made many demands upon the mechanical arts, and have steadily stimulated their progress. Science and art mutually stand to each other as cause and effect. The demand has always exceeded the supply. The supply has always, eventually, responded to the demand. The patrons of physics, and especially of astronomy, have always been willing to pay for the highest art, and no instrument-maker of genius has laboured without abundant recognition. Consider the manufacture of optical glass, which has reached its highest development in such works as those of Chance and Co., Feil and Co., and the School of Glass Technology establishment at Jena (under the control of Schott and Prof. Ernest Abbe). Here are manufactured great plates of optically perfect glass, having any required characteristic as to refractive and dispersive power, or even as to elastic and electric properties. The construction of telescope lenses as perfected by van Clark, and of microscope lenses by many artists too numerous to mention, all involve mechanical processes of the rarest delicacy, and illustrate how perfectly one class of men, the mechanicians, have been able to realise the ideals conceived by another class of men—the investigators.

The mounting of the great steel tube and all the accessories of the telescope, the construction of the revolving dome and the movable floor by such firms as Warner and Swazey, all demand the best engineering, while the delicate micrometer, with its perfect measuring screw, the spectroscope, the photometer, the camera, the chronograph and the clock, the transit instrument with its perfect pivots, the vertical circle with its delicate graduations, the altazimuth instrument and the spirit-level on which everything depends, each and all call for the most delicate manipulation, the most absolute homogeneity of material freedom from internal strain, the finest work with the lathe, dividing and planing machines, and numerous other characteristics of the highest type of the mechanical arts. For two centuries past the stationary astronomical clocks and, especially of late years, the portable chronometers used by navigators at sea, by explorers on the land, by geodesists and astronomers everywhere, have been reckoned among the marvels of mechanism. Hundreds of men have directed their best thoughts to the perfecting of these timepieces, so that they shall respond to the needs of the practical astronomers. From this work has resulted the possibility of the establishment of the manufactories of high-class watches on an immense scale, so that now everyone purchases, for a few dollars, that which a century ago it was entirely impossible to obtain. We wind our watches daily, and boast of their accuracy to within a few seconds, quite forgetful of the fact that the astronomer and mechanician had to combine together to evolve this great system by which a million of timepieces of high character are annually manufactured for popular use. But, not satisfied with this, the scientist takes the most perfect specimen of all these, and uses it in pushing his astronomical studies to a still higher perfection. Astronomy is often called the parent of all the sciences, because it is said to have been the first in the order of development. But it has also been the foster-parent, because astronomers found it necessary to develop, encourage, and protect every other branch of science in order that their own might prosper. Astronomy has demanded the most perfect apparatus. The command of large funds consecrated to this work by generous patrons has enabled astronomers to stimulate active minds and nimble figures so as to secure those triumphs of accurate workmanship that are necessary to the advance of every branch of science. In this way the sextant and chronometer come to be devised for the navigator; the theodolite, the base apparatus, the pendulum apparatus, and the spirit-level were devised for the use of the geodesist; the Gaussian apparatus for the study of terrestrial magnetism; the modern balance for the use of the chemist; the self-recorder for the use of the meteorologist. When the investigator needs better apparatus, he usually invents or designs its necessary features, and then calls in the mechanism to help construct it. The former discerns the sources of error, and the latter devises methods to overcome them. Generally, the student leads the mechanician; science directs the art of the mechanic; the mind guides the hand. The popular idea of science includes both the increase and the diffusion of knowledge. To the general English reader the scientist may be either a discoverer, an investigator, or a teacher. But the teacher cannot exist without the discoverer. Since the investigator must add to the sum total of human knowledge in order that the teacher may have something to teach, therefore he must know both what has been done by others and also how to improve upon that. He, therefore, it is who is the true inventor, the one who *finds out*, and it is he who in his desire to study deeper stimulates the mechanic to produce better tools and apparatus. Thus it is that both the astronomer and the physicist and all the special students of nature take a prominent part in the development of more perfect apparatus. They must have the means to make better measurements of length, area, and volume; of time, velocity, and angle; of weight, mass, attraction, and repulsion; of electrical current and resistance, density and potential, conductivity and capacity; of temperature and heat, expansion and radiation. They must have all the apparatus especially appropriate to the study of heat and light, elasticity, gravity and electricity. The best they have to-day will not be good enough for to-morrow.

VII. — Fundamental Improvements in Machines Follow the Development of Fundamental Principles in Science.

Every important advance in the mechanic arts has been preceded by special scientific investigation and the determination of data that were fundamentally necessary to the success of that particular advancement. This seems like a very strong and, perhaps, a rash statement. I may not have made an exhaustive examination of the subject; there may be an exception to the rule; but we shall find so many illustrations of its truth that we must accept its general application in modern times, whatever may have been true in the earliest stages of the arts. At the present time, those whose tastes incline them to research pave the road for those whose tastes incline them to invention and manufacture. The heroes of invention and manufacture would still be lost in the wilderness of ignorance had not the devotees of science prepared a highway and paved it with a solid Belgian pavement of blocks of knowledge on which all may march to success. I will illustrate this by, first of all, considering the subject of the efficiency of a machine. In the construction of a tool or machine every device has for its object to secure the attainment of some specific motion or result with the greatest possible economy of force, in the least possible time, with the least possible waste of material. The original source of our power may be falling water or tidal waves, the burning of coal or the consumption of some precious metal, it may the wind or the direct energy of sunlight, or that indirect effect of gravitation represented by the electric currents that flow through the earth and atmosphere. In extreme cases, we may go back to the old-fashioned sources of power, the horse, the dog, or the man

* By Prof. Cleveland Abbe, U.S. Weather Bureau, Washington, D.C., an address delivered before the Franklin Institute.

working in a treadmill, or travelling round and round in a circle. But in every case we nowadays have to compute the ratio between the cost of the power and the value of the work that we finally get out of it. This involves essentially the question of the relation of the motor power itself to the amount of resulting work. This latter ratio we call the mechanical efficiency of the machine; the perfect machine of modern times is characterised by a large per cent. of efficiency. For instance, we use an axe to split logs of wood. A dull axe, or one whose blades are rough or wrongly inclined to each other, will waste a large percentage of our strength in friction and unnecessary resistances. After we have given it a sharp edge and a proper angle of cleavage, we still have to consider the ratio of its weight or mass to the power available in our muscles and the resisting power of the log that is to be split. With a small mass in the head of the axe, such as 3lb. to 5lb., we should in vain attempt to cut the tough wood that would yield to a heavier axe of from 5lb. to 7lb. Among our natural sources of power we reckon the wind as one of the earliest to be used, and still one of the most important. To increase and to measure the efficiency of a windmill is a problem that has taxed the genius of our best inventors and students. It is not measured by the quantity of work done per hour, but by the ratio of that to the work done by the wind in passing between the sails of the windmill. Having given up some of its momentum to the sails, the wind must still retain a large portion in order that it may move onward and make room for a fresh supply of air that is coming onward from behind. It would not be advisable to abstract from the wind more than one-half of its momentum, therefore, from this point of view, the efficiency of the windmill sail should not exceed 50 per cent.; this is the external efficiency of the mill. If we now compare the work done at one end of the machine with the energy of the revolving windmill-sails at the other end, we obtain the internal efficiency of the mill, which in properly-constructed apparatus may be as high as the factor for the best machinery of any other kind; but, in fact, the windmill is not generally constructed with great care, and Prof. Franklin B. King, of Madison, Wis., finds but a small percentage for the best windmill investigated by himself. The mechanical efficiency of a machine is now recognised as a matter of the very highest importance. Much of our manufacturing competition is based upon the relative merits and relative expenses of running our machines. The modern methods of measuring efficiency and of investigating the sources of waste emanate always from those who are fully alive to the laws of force involved in all mechanical operations. They are essentially due to the physical laboratory and the mechanical laboratory. They often involve mathematical considerations of a very abstract character. Many an engineer keeps the records of his indicator card and sums up the foot-pounds per minute in a mechanical sort of way that shows that he can have no conception of the labour given to the study of thermodynamics before this simple device could be made equally useful to the manufacturer and to the inventor. The former sees in it a record of how much his engine is wasting, the latter sees in it suggestions as to how to improve the machine. The indicator card is an application of physical laws to practical machine work that has during the past fifty years been quietly revolutionising the construction and use of the steam-engine. The injector, first made by Giffard, a French engineer, which, by the way, has received numerous important modifications by William Sellers and Co., of Philadelphia, must be allowed to be not an efficient machine from a mechanical point of view. But, from a thermal point of view, it is almost perfectly efficient, since all the heat of the steam and the feed-water goes back into the boiler; it is this that enables it to add to the efficiency of the steam-engine as a whole. The Bessemer process for making steel is a good illustration of a method that is highly efficient mechanically, thermally, chemically, and I may also say chronometrically, since the time required is reduced to a minimum, consequently also financially, and it is no wonder that we have now suddenly arrived at the age of steel as distinguished from the age of iron. The process of welding by means of the electric current is another illustration of an economy of time, fuel, and power that is truly remarkable. You will perceive that all these improvements were preceded by a long series of laborious scientific determinations of the necessary fundamental data. The pumping of water by means of reciprocating force-pumps, as distinguished from the rotary pumps, is a very ancient process, the crudeness of which, from a mechanical point of view, might have been thought to have been overcome by the rotary and centrifugal pumps. The reciprocating pump is still indispensable when great heights or resistances are to be overcome; but it is recisely also in this case that the strains upon the machinery are most dangerous to its welfare. Here come in the improvements made by your fellow-member, Mr. D'Auria, whose devices have overcome important difficulties experienced in other machines, while at the same time he attains a remarkably high percentage of mechanical efficiency. If his construction of tubes and his arrangement for the flow of water and diminution of shocks is properly analysed, it will, I think, be seen to be the outcome of a long study into the flow of water in rivers and channels. His application of theoretical hydrodynamics to the construction of pumping machinery is a fine illustration of my general principle that all the higher improvements that our present types of machines have received or are still susceptible of, in order to become more perfectly efficient, can only come from that profound study of mathematical and physical principles that belongs to the scientific and technological courses of our universities. If any further evidence were wanted, you have only to consider the other side of the case, viz., the fearful sacrifice of time and money, human thought and human life, that is represented by the thousands of useless devices that are annually patented by over-sanguine inventors. These usually proceed from men of little education or experience, who have heard, perhaps, that John Smith made a fortune out of his little invention, and vainly imagine that whatever is new and patentable is naturally of some value. It would be impossible to quote to-night all the important inventions, even by members of the Franklin Institute, that illustrate the importance of economy and efficiency as the prime characteristic of any great invention; but I will mention, still, the brilliant invention of the sand-blast by Mr. B. F. Tilghman. This simple jet of air or steam with sand does in a few minutes the work of cutting that the finest engravers might spend years in doing. It substitutes machinery for the engraver's hand; but, of course, it cannot replace the artistic imagination of the famous cutters of gems. The mechanical principles involved in this process were explained by Prof. Osborne Reynolds in the *Philosophical Magazine* for November, 1873. The first and fundamental item is a law of impact—viz., that at the instant of first contact the pressure between two bodies is independent of their size, their mass, or their velocity, but depends principally upon the density of the bodies and their hardness, so that a dense soft body may cause as much pressure as a less dense but hard body. Singularly enough, very much the same principle applies to the soaring flight of a horizontal plane surface flying through the air. If the plane were to fall vertically from rest to the ground, it would quickly set all the air below it in motion outward in all directions, and would fall more rapidly because falling with the moving air; but, when flying horizontally, it experiences at every moment the necessity of giving motion to a fresh mass of quiet air. It falls more slowly, as if experiencing a greater resistance. In this way, the air, considered as a soft body, causes an upward pressure sufficient to support a heavy body for a long time. So in the sand-blast, the first effect of the impact of the grains of quartz is to impress on the molecules of the softer glass a slight motion, which is a certain percentage of the movement of the harder particles of sand, and just sufficient to tear them away, one at a time, from the rest of the glass. You will perceive that Reynolds's law applies again to the polishing burr-wheel, to the spinning of sheet-iron and tin plates, and to the cutting of stones, metals, and glass by the edge of the rapidly-revolving wheel of soft lead or copper. Prof. Reynolds shows that, in order to produce the same effect, a sand-blast that is cutting into lead must have a velocity about eight times as great as when cutting into the glass, the ratio depending upon the relative densities of the lead and glass. The geologist has occasion to apply these principles, since the sand-blast is always at work eroding the face of the earth with the help of wind and water. I cannot refrain from quoting another modern invention that illustrates the recent application of simple physical principles to machines. I do not know the personal history of the inventor of that which we call the "Babcock Cream Separator," but he must have been a student of physics who first proposed to substitute centrifugal force for the force of gravity. As you all know, the particles of cream rise to the surface of quiet milk because of their buoyancy. Cream is specifically lighter, or has less density than water. Gravity pulls down the water harder than it pulls the milk, and therefore the water pushes the cream up by a hydrostatic pressure that it owes to the attraction of gravitation. Mr. Babcock puts his milk into a rapidly-revolving cylinder; the rotation gives rise to a centrifugal force, all particles have the same rotatory velocity, but, each particle of water being denser than a particle of cream of the same size, is pressed outward by its centrifugal force more forcibly than the particle of cream. Thus, therefore, a great centrifugal force is used in place of gentle gravity to generate a great difference in centrifugal pressure, and thus quickly force the separation of the water from the cream. In a very analogous way, the drier in a modern laundry, whirling rapidly around, separates the water from the wet cloth by centrifugal action. So, also, the whirling atmosphere of the earth drives cold air from the North Pole toward the Equator, pushing aside the warm south winds. Among the many branches of physics that are studied in the laboratory, none has more interest than the flow of metals, whether elastic or non-elastic. All that we have learned about this subject has found immediate application, first, in the improvement of the ancient process of wire-drawing, second, in the modern process of rolling rails, again, in the still more modern process of drawing the seamless tubes, and, finally, in the rolling of the immense plates for our ironclads. The steam locomotive is often said to have begun with the work of Oliver Evans, of Philadelphia, in 1772. The improvements made by George Stephenson, of England, for a while gave English engines a high position as models; but since those days Philadelphia has come to the front, and the Baldwin Locomotive Works are now sending their engines to England herself. You all know from personal experience that the modern locomotive embodies at every point the best thought of investigating physicists, and illustrates again the absolute necessity of securing for our inventors, engineers, and manufacturers the best graduates of our best techinal schools. You will not, therefore, be surprised if I emphatically urge upon your attention the general principle that the relation of astronomy and physics to the mechanic arts is not wholly an historic one, in that astronomy and physics preceded and fostered all important improvements; nor is it merely one of dependence, in that astronomy and physics look to the mechanician for the perfect apparatus. It is not merely a relation, but a relationship, and a close one. It is a twinship, in fact, a Siamesian twinship, where the blood of each flows through the other. If art is the right hand, science is the left. If one is the tool, the other is the worker. Neither advances without the other; if one steps forward to-day, the other steps forward to-morrow. Among the most important features of the development of modern mechanics has been the introduction of a class of machinery sometimes designated as machine tools, by which we mean machinery that is more or less perfectly automatic and is designed for the construction of many copies of some one part of another machine rather than for the direct manufacture of crude material as in textile work. These parts were formerly made entirely by hand; they were forged or filed, sawn and hammered, scraped and polished until they were of the proper size, shape, and smoothness. A watch, for instance, is a machine intended to keep correct time; every portion of it, from the minutest screws and pivots to the chasing on the outside of the cover, was formerly done by skilful hands, and the expenditure of time and labour was enormous, while the resulting mechanisms always presented minute differences, such that no two similar parts of two watches could be interchanged. Now, however, tools are available by which every part of the watch is made by machinery. The human hand and eye scarcely ever intervene, the similar parts are always interchangeable, and the resulting watches are, to a very great extent, perfectly comparable with each other in their performance as timekeepers. Just as a file is a simple tool in the hands of the workman, so the Waltham lathes, planing machines, engraving machines, screw-cutting apparatus, and drilling machines are complex tools—namely, machine tools—for manufacturing the parts of the watch. The history of the modern development of the mechanic arts is the history of the application of the highest science to the perfection of the machine tools. But a machine tool may be almost useless without the steady supply of power necessary to drive it. The foot-lathe is a simple machine tool, but it cannot be applied to fine work on a very large scale, such as that now required, owing to the unreliability and irregularity of the power that is used as the prime motor. The development of the modern lathe and its application to innumerable problems was necessarily dependent upon the invention of the steam-engine, the turbine-wheel, and the dynamo, all of which furnish an abundant and perfectly equable supply of power that can easily be transmitted to any desired spot. Among the important machine tools we may quote the lathe as applied to the cutting of screws and the production of all manner of symmetrical surfaces; the planing machine for flat and curved surfaces; the drilling machine for cylindrical pits; the boring machine for hollow tubes. Modifications of the lathe are seen in the vertical drilling machine and the slot-drilling machine. The machinery for making the blocks that are used in connection with tackle was one of the earliest machine tools. The trip-hammer, as modified by Nasmyth into the steam-hammer, works as if endowed with intelligence. The rivet machine replaces hundreds of labouring men, but makes it possible to set thousands at work on other lines. A very important class of tools is that for testing and measuring the dimensions and the fitting of the various parts of a machine. When once a perfect machine or tool has been made, there immediately comes a demand for perfect copies of it, and these cannot be made without accurate measuring machines and machine tools that are correspondingly accurate. The great advantage to be derived from the system of manufacture in which each part of a machine is identical in size and shape

with the similar parts of other machines was appreciated in England many years ago, and was especially insisted upon by Sir Joseph Whitworth. The perfect measuring machines that are necessary to carry out this idea have, however, been manufactured and used most freely in this country, William Sellers and Brown and Sharpe being well known in this work. The average errors of properly-made interchangeable parts of a machine will not, in the present state of the art, exceed $\frac{1}{1000}$in., and even in the largest cylinders and pistons of a steam-engine freshly turned out of a huge lathe there ought not to be an error of $\frac{1}{100}$in. or the ten-thousandth part of their own diameter. Still greater accuracy can be attained whenever needed. Some of the heaviest and, at the same time, most accurate machine tools are those built for the purpose of manufacturing heavy ordnance, armour-plate, and the machinery of the great naval vessels of the world. In the construction of these the best engineering talent and the soundest scientific knowledge are always utilised. They illustrate the best that can be done at the present time; but who can tell what another year may bring forth? We have spoken of the mechanic arts as though we have to deal only with working tools and moving machinery; but, of course, all great stationary engineering structures being themselves the products of the mechanic arts, illustrate, on the one hand, the perfection to which the arts have attained, and, on the other hand, the physical problems that must be solved in the course of this progressive development of the arts. Within our own lifetime we recall such monuments as the tubular bridges over the Menai Straits and over the St. Lawrence, the suspension bridges over the Niagara and the East Rivers, the London Crystal Palace of 1851, the Eiffel Tower at Paris, and the Ferris Wheel at Chicago. These were only possible after machinery had been devised for rolling the iron and steel, cutting and bending it, punching and bending it, punching and twisting it in all directions, and, finally, testing every portion of the structure as to its strength and expansion with stress and temperature. Even in the fine arts, our pianos, organs, and brass instruments respond to the increasing knowledge of physics and the finer arts of the modern mechanic. Only the violin remains as yet unimproved by the progress of the mechanical arts. Perhaps the modern bicycle illustrates, in a small way, that which the dynamo and electric motors do in a large way, the fact that at every turn our knowledge of physics is of vital importance to our future progress. It is about thirty years since the first French bicycles made their appearance. The idea—that is to say, the invention—was ingenious, but it was impossible to popularise this vehicle in its first crude stage. The wheels were simply those of a small ordinary waggon; the tire was iron for the sake of durability; both front and back wheels were too large, so that an unnecessary strain was brought upon the rider, which proved disastrous to many. Since those days successive changes have taken place; the iron tire is replaced by the indiarubber pneumatic tube; the heavy wheel of the wheelwright gives place to the elegant steel wheel and frame; the chain and sprocket give place to perfectly bevelled cog-wheels and rods. The fatiguing journey then indulged in as an athletic exercise now becomes the regular and easy work of an hour in discharge of one's daily duties, to say nothing of touring for pleasure, day after day, all summer long. Every step in this progress has been, and every future step in development will be, but an application of principles discovered and taught in the physical laboratories of our universities.

(To be continued.)

THE new passenger jetty at Colombo has been finished.

THE work of fitting the United States torpedo boat *Talbot* with machinery for the use of liquid fuel is in progress at the Norfolk (Va.) navy yard.

IRON mines have been started in the new Cehegin-Calasparra district, near Cartagena, and a cableway is now being built from the mines to the nearest railway station.

THE Phos Acetylene Gas Co. are exhibiting at Earl's Court Exhibition between 30 and 40 different kinds of portable lamps. This firm claims to be the only one which has devoted itself exclusively to portable acetylene lamps, and their exhibit includes table lamps, carriage, ship, and cabin lights, lamps for mining, night excavating, shaft sinking, engine fitting, &c., in every case complete with generator. They have in the larger forms of lamps overcome the difficulty in connection with frequent charging, inasmuch as the generators are now made that the lamp can be used as many as six times without recharging. The Phos Co.'s lamps are used in the milling exhibit at the Exhibition, and their practical utility will be at once apparent to all. We have ourselves found the portable table lamp both ornamental and useful, as it gives a brighter light than oil, whilst the same is so thoroughly diffused that it is easy to read even when holding a book between the light and the eye.

SCIENTIFIC NEWS.

IT appears that although Swift's comet (1899 *a*) is practically invisible, it is worth while to keep an eye on it, as it exhibits some remarkable variations in brightness.

Holmes's comet is in a good position for observation, but it is doubtful whether any good observations will be made. Its position is about R.A. 3h. 3m., N. Dec. 40° 2'.

The following paragraph appears in one of the London morning papers:—Prof. Pickering, who is known in connection with discovery of the Satellite of Saturn, is reported to be favourably impressed with the atmospheric conditions for the use of the remarkable telescope now being made at Harvard University for photographing the new planet Eros. The designed focal length is 162ft., while the aperture may exceed a foot by only an inch or two. It is intended to mount the instrument permanently in a horizontal position, and to observe or photograph the image reflected by a mirror, the earth's motion being compensated for by a clockwork arrangement. This novel instrument will be practically a horizontal photo-heliograph, giving images of the moon exceeding a foot in diameter. Perhaps this is like the Paris siderostat illustrated on p. 191, April 14, 1899.

The death is announced of Prof. James Cuming, M.D., F.R.C.P.I., who for many years had occupied a leading position in the medical profession in Ulster, and whose name was well known on both sides of the Channel. Born at Market-hill, County Armagh, in 1833, Dr. Cuming was educated at Queen's College, Belfast, obtaining the degrees of Doctor of Medicine and Master of Arts in the Queen's University, subsequently becoming a Fellow of the Royal College of Surgeons in Ireland. He also studied at Vienna. On settling in Belfast, he rapidly secured a very extensive practice, and for a considerable time past held the foremost position as a consultant. In 1865 he was appointed to the chair of Medicine in the local Queen's College, and also became a member of the medical staff of the Royal Hospital, of which he had for many years been senior physician. He was also consulting physician to the Ulster Eye, Ear, and Throat Hospital, and chairman of the governors of the Belfast and District Lunatic Asylum. A ripe scholar both in professional and general literature, he acted with great success as president of the British Medical Association during the visit to Belfast of that body in 1884, being subsequently elected a permanent vice-president.

English horticulture has sustained a great loss in the death of Mr. Thomas Francis Rivers, of Sawbridgeworth, Hertfordshire. He was the son of Mr. Thomas Rivers, the founder of the advanced system of fruit culture which during the last 50 years has placed this country far in advance of all others. He was a member of the council of the Royal Horticultural Society.

It is stated that owing to the precautions taken the death-rate from tuberculosis (Lungenschwindschuct) in the German army has fallen from 0·42 to 0·24 per thousand in 1898-99. In the Bavarian army the decrease in cases has been 2·3 and in the death-rate 0·32 per thousand. The number discharged from the German army on account of the disease during the five years ending in 1896 was 7,205, or 51·9 per thousand of those discharged for any reason whatsoever. It must be remembered that no man is admitted into the army who in the medical examination which precedes entrance is found to be suffering from the disease; apparently, therefore, it is contracted in the army. The chief predisposing cause is stated to be a "cold"; the next in importance is the strain of military duty, but this does not include the blowing of musical instruments, which comes under a separate heading. The treatment was more or less successful in 23·3 per cent. of the cases; in 1·2 per cent. a perfect cure was effected. In the remaining 76·7 per cent. the treatment failed, and death resulted in 16·1 per cent. The decrease in the number of cases in recent years is attributed largely to the discovery of the bacillus of the disease by Koch in 1882, owing to which it is easy to detect the disease and reject recruits suffering from it who would otherwise have passed the medical examination.

The number of deaths from the administration of chloroform are bringing that anæsthetic into disrepute. Mr. C. W. Krohne calls attention to the reports of two inquests recently held, and it does seem certain that if medical men cannot administer chloroform without causing death it is time that an inquiry should be held. It is asserted, and on the best authority, that chloroform can be administered safely in every case; but deaths are frequently reported, and the juries seem perfectly satisfied.

During the meeting of the British Association, the Mayor of Dover, Sir W. H. Crundall, J.P., assisted by a representative managing committee, purposes holding a three days' show of automobiles. The secretary is Mr. F. E. Beeton, Park-street, Dover, and all particulars of intended exhibits should be forwarded to him by Sept. 4. The show will be held on Sept. 19—21.

In a memoir contributed to the Paris Academy of Sciences, MM. Berthelot and Delépine state that dry silver acetylide detonates when heated in a vacuum. They also state that the temperature is sufficient to volatilise the carbon, and that the flame from the acetylide approaches a temperature of 4,000° C. If that is correct, it ought to be a very useful temperature in many of the arts; but perhaps there is some mistake.

Boiler pressures are going up steadily, and those who can remember the remarks of Watt will wonder what he would have said. Some new heavy ten-wheeled passenger engines built by the Schenectady Locomotive Works for the New York Central Railroad weigh over 73 tons. The total wheel-base is 26ft., the cylinders are 20in. diameter by 28in. stroke, the heating surface is 2,886sq.ft., and the grate area 30·32sq.ft. The boilers are designed for a pressure of 200lb.

It is stated that Chicago is about to utilise the current of sewage in its drainage canal for lighting and other purposes, and a dam is being constructed where the stream discharges into the Desplaines River. At this point there is a head of 16ft. It is estimated that the work will cost only £66,000, and that 15,000 or 16,000H.P. will be obtained with the present maximum flow of sewage. This is quite a new device in the utilisation of sewage, and possibly something might be done with the enormous volume discharged by the northern sewer of London.

A curiosity in wheat has just been brought to light at Wisbech, where Mr. Holmes of North Brink has had in his possession a sealed jar containing wheat that is sixty years old. This grain was grown upon a field in Barton-road at Wisbech, and there is no doubt about its having reached the hoary age of three-score years. Mr. Holmes has just handed over the little hoard to a firm of Boston millers, who have examined the wheat and found it in an excellent state of preservation, its condition comparing very favourably with wheat of last season's growth. It is now intended to sow a part of the grain this season, and the remainder will be re-sealed, to be kept for a longer period, the object presumably being to test the vitality of English wheat. The experiment exemplifies the marvellous keeping properties of wheat under the best conditions. But what is sixty years compared with the 3,000 years ascribed to the Egyptian mummy wheat, which has been re-sown and has shown its vitality after the lapse of ages.

The *Ermak*, which has arrived in the Tyne, has completed a cruise in Polar seas, and broken all previous records. For fourteen days continuous steaming was kept up to the north-west of Spitzbergen. Dense fields of ice were encountered for 200 miles, and were broken through without the slightest interruption, the estimated thickness being 14ft. on one occasion. The crew passed through many exciting adventures. Immense floating islands of ice were met with, and in several instances, from soundings taken, their depths proved to be seven fathoms below the surface.

In spite of the recent rain, the Thames at East Molesey and Hampton Court was on Tuesday 2ft. 3in. below summer level. The river is now lower than it has been for the past 40 years. No water has passed over the weir for some days, and in consequence of the shallowness of the river several barges are unable to get through Molesey Lock. At Tagg's Island the sides of the river have the appearance of a seaside beach, the boats of the local watermen being left stranded, while the rollers at the lock cannot be approached on account of the lowness of the water. A few months ago the floods were out, and riparian residents were inconvenienced. The Thames Conservancy needs reforming.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

THE PERSEIDS—HOLMES'S COMET.

[42745.]—This rich annual shower was very well observed by myself, two other members of the B.A.A., and my two brothers from the tops of the Malvern Hills during the two chief nights of its long-enduring display—viz., August 10 and 11. Between us, during the two nights, we saw in round numbers 500 meteors, by far the greater majority of which were Perseids. We were favoured with exceptionally fine weather, not a cloud being seen in the sky on either night.

During the first night our watch was on the Worcester Beacon, altitude about 1,500ft. above the sea. We did not begin our watch till 12h. 15m., and then kept on till 15h. 30m. During this time 226 meteors were seen by three observers, about 200 of which were Perseids. Only the paths of a very few of the brighter ones were registered, as the main object was to ascertain the horary average and time of greatest frequency; consequently, very few meteors were missed during the watch.

The time of greatest frequency on both nights was about 14h. Between 13h. 15m. and 13h. 45m. on the 10th, 36 meteors were seen by two observers; and between 13h. 30m. and 14h. on the 11th, 36 meteors were seen by two observers.

The time of greatest frequency was on the 11th, when meteors were falling at the rate of 92 per hour, from 13h. to 13h. 15m. During this time 23 were seen; 14 of these fell from 13h. to 13h. 5m. The brightest on either night were seen about 14h. On the 10th one was seen at 13h. 55m. equal to Venus at its brightest; and on the 11th two magnificent meteors were seen, one at 13h. 44m., twice as bright as Venus, and the other at 13h. 57m., three times as bright as Venus. These three meteors partially lit up the sky, and left trails for about half a minute. One of their paths was obtained, and was from R.A. 21h. 45m., Dec. S. 17° to R.A. 22h. 30m., Dec. S. 23°. This was the one seen at 13h. 44m.

Of 74 meteors seen on the 11th, of which the magnitudes were estimated, eight were of the 1st mag., 16 of the 2nd, 11 of the 3rd, 6 of the 4th, 9 of the 5th, and 21 of the 6th mag. Besides these, one was half as bright as Jupiter. The remaining two have been mentioned above.

The following table gives the number of meteors appearing every half-hour during the time observations were made during the two nights, for two observers:—

Date.	G.M.T.	Number of Meteors seen.	Date.	G.M.T.	Number of Meteors seen.
1899.	h. m. h. m.		1899.	h. m. h. m.	
Aug.10	12 15—12 45	26	Aug.11	11 0—11 30	15
,, 10	12 45—13 15	26	,, 11	11 30—12 0	18
,, 10	13 15—13 45	36	,, 11	12 0—12 30	27
,, 10	13 45—14 15	25	,, 11	12 30—13 0	23
,, 10	14 15—14 45	10	,, 11	13 0—13 30	23
,, 10	14 45—15 15	4	,, 11	13 30—14 0	36
			,, 11	14 0—14 30	34
			,, 11	14 30—15 0	29
			,, 11	15 0—15 30	2
			,, 11	15 30—16 0	3

Thus, in three hours on the 10th, two observers saw 127 meteors, and, in five hours on the 11th, two observers saw 210 meteors. A third observer saw on the 10th, between 13h. 35m., and 14h. 35m., 51 meteors in another part of the sky. Two observers only watched on the 11th, myself and Mr. Alfred Watson, from the North Hill, altitude about 1,400ft. above the sea. The last meteor seen on the 11th was at 15h. 55m., in bright twilight, and of the 1st magnitude. The watch on this night extended from 11h. to 16h. The shower seemed to be equally fine on both nights. As will be seen from the above table, the time of maximum was later on the second night than on the first. A glance will also show that each night the meteors gradually increased in number, and then fell off towards morning.

I should say from our observations that the maximum of the shower was about 14h. on the 11th, as meteors fell then at the rate of 70 per hour. (See table from 13h. 30m.—14h. 30m.)

A very curious meteor was seen on the 11th, at 14h. 30m. in the west, low down. It was very faint, about the 4th magnitude, with no streak, and had a very long path. It appeared to move somewhat slowly, and did not seem to go quite straight. Its duration was about 5sec.; it path was from R.A., 16h. 20m., Declination N. 32, to R.A., 14h. 0m., Declination N. 46. This was not a Perseid; it was low down on the western horizon, and came from somewhere in Hercules.

Has anyone seen Holmes's comet yet, as I should like to know what magnitude it is, and what is the smallest aperture it can be seen with? I have searched for it recently in my $2\frac{1}{8}$in. refractor, but can find no trace whatever of it.

Ivo. F. H. Carr Gregg.

Maynard Cottage, W. Malvern, Worcestershire.

THE BRITISH ASTRONOMICAL ASSOCIATION AND THE ROYAL ASTRONOMICAL SOCIETY.

[42746.]—I should like to know what is supposed to be a "bar" to the fellowship of the R.A.S. In a penny London morning paper I find a notice (it cannot be called a review) of what is known as the "eclipse volume" of the British Astronomical Association," the opening sentence of which is: "The British Astronomical Association was founded some ten years ago for the advantage of intercourse between amateur astronomers whose means or qualifications might be a bar to fellowship in the Royal Astronomical Society."

What "means or qualifications" are a bar to fellowship in the Royal Astronomical Society? I do not believe the Society recognises any such "bar." I am inclined to believe that the "critic" knows nothing of the subject, and I am confirmed in that belief by the last sentence of this precious review, in which it is stated that, "If the summary of results given in a concluding chapter of the volume show that no important addition to our knowledge of solar physics has accrued from the observations, they at least supply further material for the solution of problems."

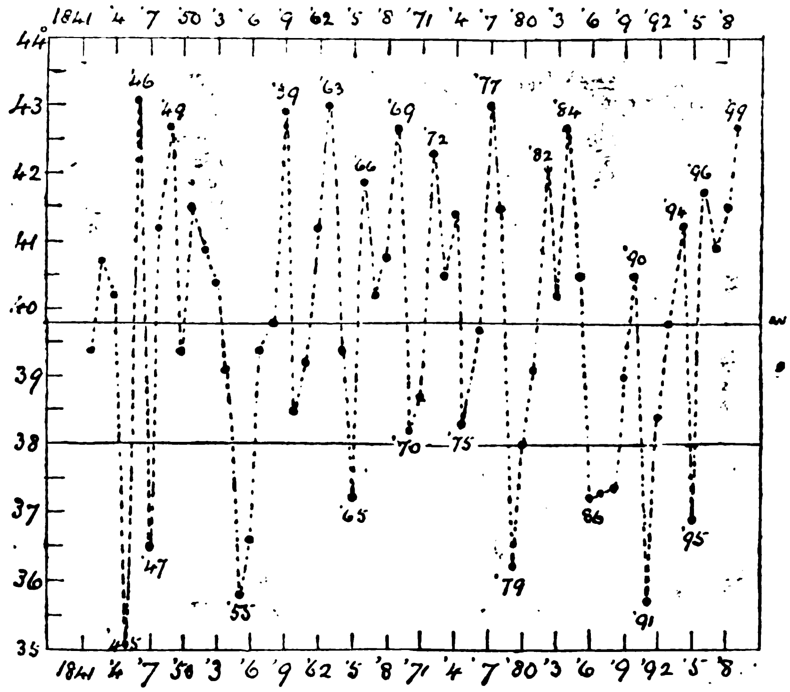
I suppose the writer has some idea of what he means; but I have an idea that it is as hazy as his grammar is rocky. In hazy weather the most experienced seaman runs a risk of running on rocky ground.

An Old Printer.

SOME FACTS ABOUT LONDON WINTERS.

[42747.]—Winters may be studied from various points of view. The item I propose to consider here is the mean temperature of the period December to March, as given in the Greenwich records since 1841. For brevity, we may designate each winter by the year in which it ends (e.g., 1842 meaning Dec. 1841 to March 1842).

The variations of winter, so considered, are given in the curve herewith; and the following may be noted as curious features of this curve.



1. Distinguishing winter above the average as *mild*, and those below as *severe*, we find these winters severe (some conspicuously so): 1845, '55, '65, '75, '86, '95 ('85 was rather mild).

2. Suppose we draw a line at 38°, and call winters under this *very severe*, we find the following have this character:—1845, '47, '55, '56, '65, '79, '86, '87, '88 ('91), '95. We may note about these eleven winters that all except one ('91) are in the later half of a decade (represented by 5 to 9). No winters ending in 0, 2, 3, or 4 have been very severe.

3. On the other hand, there are very mild winters in most years of the decades (0 and 5 being excepted).

4. We find a succession of four severe winters on two occasions—viz., 1854, '55, '56, '57; and 1886, '87, '88, '89. These cold times are, say, 32 years apart, which is about the period of Bruckner's cycle (35 years on an average). The second group is separated from two more severe winters by the moderately mild winter 1890.

5. We have just had four mild winters, 1896, '97, '98, '99. Shall we have a fifth? That seems unlikely, as there has never been, since 1841, a succession of five. There are two groups of four besides that specified—viz., '66, '67, '68, '69; and '82, '83, '84, '85. On the other hand, next year is 1900, and as no winter ending in 0 has been more severe than 38° (1880), we might be disposed to expect no extreme severity. But I do not lay stress on this.

Your readers may be interested to trace further relations in the curve. This particular curve is not so suggestive of sunspot influence as some winter curves, I think, are—those relating to the first quarter especially.

Alex. B. MacDowall.

Gadebridge, Crouch End.

"PROF. BONNEY'S STORY."

[42748.]—The quotation I made (p. 15) was from no sermon, but from one of the lessons the professor is bound to read twice every year. Formerly they were read thrice a year, but the *New Lectionary* reduces the readings to two. St. Luke xvii. 26 is read *Feb.* 13 (a Sunday this year) in the morning, and *Oct.* 14 in the evening. The other, in St. Matthew xxiv. 38, is also read *Feb.* 13 morning, and *Aug.* 15 evening: "And as were the days of Noah, so shall be the coming of the Son of Man. For as in those days, which were before the Flood, they were eating and drinking, marrying and giving in marriage, until the day that Noah entered into the Ark, and they knew not till the Flood came and took them all away; so shall be the coming of the Son of Man."

Now, if the Flood was allegorical, as Mr. May teaches (p. 40), and no physical catastrophe, what is to be said of the Saviour predicting as above? I cannot see what Prof. Bonney can call him, pretending to knowledge that he never possessed. This may be the view Mr. May has been taught to hold, but I object to paying any reverend clergyman for it.

Mr. May also (letter 42722) shows himself ready, if he discovered the Ark timbers, to use them in letter exact way I have cautioned you against in letter 42491, p. 401. Let me repeat that they should not publish their discovery, even as much as Dr. Nouri, before petitioning the Sultan for soldiers to guard the relics.

E. L. Garbett.

ELECTRO-METALLURGY.—DEEP MINING.

[42749.]—HAVING seen in last "E. M." to hand (June 30) an article on Electro-Metallurgy, I thought perhaps that the report of the July 15th meeting of the Chemical Society of this place would form an appropriate supplement; as in the president's address is a description of the most up-to-date practice on these fields.

Inclosed also is a paper read by Mr. Yates before the Association of Engineers, on "The Mines of the Future," extracts from which may interest readers of "Ours" in other mining countries.

The "Consolidated Goldfields" have now under consideration the sinking of shafts over 5,000ft. vertical depth. The "Catlin" shaft of the "Jupiter G. M. Co." is now over 3,000ft., and is still being sunk. The rise of temperature being only 1° Fahr. for every 203ft. will enable profitable mining to be carried on at unprecedented depths.

Johannesburg, S.A. R., July 31. F. B.

PRESIDENT WILLIAMS'S ADDRESS.

Some ten years ago the stamp mill was the only metallurgical operation in existence for the recovery of gold, and, with a few exceptions, these were in a crude state, free gold and amalgam being found in the tailings, while to-day I think we may say that our mills and the work done in them will compare more than favourably with any other part of the world. The chlorination process, with the necessary Frue Vanners, was started in 1889, and though it is one of the most perfect metallurgical processes that has ever been discovered, its high working costs have resulted in its being supplanted by the less perfect but more profitable process, that of hydraulic classification, and subjecting the products to varying time of leaching with cyanide of potassium solution. Here I would like to add that, while we have reason to congratulate ourselves upon the high state of perfection that has been attained in the use of this process, you must not forget that it could never have been done so had not the local ore been so particularly amenable to such treatment. When the cyanide process was first started on the Rand its sphere of operations was very limited—the use of agitating vats capable of working one ton charges with a 2 per cent. solution rendered its profitable application very small. To emphasise this, I would mention that the introducer of this process refused to grant me permission to work it upon 8dwt. tailing, giving as his reason that there was no margin of profit. To-day 1½dwt. tailings yield a fair working profit. How has this been accomplished? By the joint labour of the engineer and the chemist and metallurgist, and last, but not least,

THE COURAGE OF THE CAPITALIST,

who has not hesitated to put half a million of money to develop a mine, with the necessary surface equipment, before the first ounce of gold could be obtained. I think you will agree with me that the most essential improvements are due: (1) Working on a larger scale. (2) Direct filling, which has brought the cost of handling from 2s. 9d. down to 5d. per ton (or a saving of more than the total cost of treatment in some of our modern plants), and effected a saving of cyanide of from 3s. to 4s. per ton, permitting a longer time for treatment, as preparatory washes are not required. (3) The use of weaker solutions, and the open door of all works giving free exchange of ideas, and at the same time creating a spirit of emulation among our workers. (4) To the engineer who, in addition to perfecting the mechanical appliances, has raised the status of the cyanide workers from a drudge to an intelligent worker, by enabling him to have sufficient time to give more attention to the more essential points of the process. (5) To the invaluable work done by our chemists, who have been most indefatigable in finding out the seats of mischief, and giving us remedies for same. It is only about two years ago that the problem of slimes treatment was tackled in a practical form, a product that was considered previously as worthless and cumbersome. I am pleased to be able to say to-day that slimes treatment is an accomplished success, slimes of 2½dwt. giving a direct profit of 5s. and upwards per ton. It is with great satisfaction I am able to point out that the great discrepancy mentioned by one of our former presidents (Mr. Chas. Butler) between the gold called for and the gold obtained has now practically disappeared, and I am sure it will be a matter of pleasure to all of you to know that a fair profit is being made on slimes of less than 2dwt. in value. This, I consider, the Chemical and Metallurgical Society should be proud of, as so large a proportion of this success is due to its work. So much, gentlemen, for the past and present. It will be

A SOURCE OF SATISFACTION

to you to know that, after a careful examination of the returns of several companies, an average actual extraction of 90 per cent. and over was obtained. I have no doubt but there is still plenty to do in the margin of the 10 per cent. Some of my friends seem to think that all the work has been done, and that now all we have to do is to let well alone. That would be the greatest mistake in the world. Our watchword should be, must be, and will be: Progress, Progress, Progress. It may be generally admitted that a 60 per cent. recovery from sands, &c., is very easy, that 70 per cent. requires more skill and attention, and that after a certain point every 1 per cent. becomes more and more difficult to obtain. Have you ever thought what 1 per cent. extra extraction means? It would mean an extra profit of £200,000 per annum from these fields. As a suggestion as to how these extra 1 per cent. may be obtained, I would say, pay every possible attention to the fitting of your tanks, thereby eliminating all the slimes, and in your slimes plant—beware of sands—endeavouring at all times to keep each product in its own department. I cannot emphasise this point too strongly if you wish to make improvement. Give much more thought and time to your precipitation, as good work in this department means a decrease in the soluble gold in your residues, and a consequent lower value. At present, final water washes have to be limited, but I hope that Mr. Coldecott will shortly read a paper on a new process he is introducing, and go more fully into this branch. Due attention to the alkalinity of mill water and slimes solution will be remunerative, as good settlement in residues means less gold leaving the works. I would like to add that "cleanliness being next to godliness" applies as much to cyanide works as to anything else. We have had several very interesting papers on assaying during the past year, but I am of opinion that far too little has been said about the absolute necessity of care and competency in sampling, without which the work of the assayer is

LABOUR IN VAIN.

The same applies to mill tonnage, for unless these two factors are dependable, any comparison of recoveries between two companies is of no value. As a case in point, I may mention an instance where a company had an actual recovery of 102 per cent. of the assay value of the ore going to the mill, notwithstanding the fact that their slimes were untreated, and the cyanides residues were 1dwt. (Laughter.) I am looking forward to an interesting paper on this subject from Mr. S. H. Pearce at an early date. I am certain it will be interesting, and I hope it will be followed by others. Sampling and tonnage, gentlemen, are the foundation stones upon which our entire superstructure is built, and their importance cannot be exaggerated. I am aware of a cyanide manager who takes a true ton of 20 cft., after several estimations, who had his attention drawn to the fact that his discrepancy of 3½ per cent. between actual and theoretical extraction denoted poor work, because his next-door neighbour had a difference of only ½ per cent. The manager, perhaps, did not know that this man was taking 7½ per cent. more than his true ton. I am, however, pleased to say that this cannot last much longer, as slimes plants will soon be found necessary on all the mines, and decrepancies in tonnage will not be tolerated. The successful working of tailings plants has increased the crushing efficiency of our mills very considerably. In the past it was a case of catch all the gold you can on the plates, as the rest was lost. Of late there has been a great tendency to crush very coarsely, because you can catch more sand in the cyanide works. This I have proved to be a dangerous policy. I will only give you one instance. A new mill was started, and because their neighbours were using a 700 mesh they did likewise, with a result that their first residues ran 3dwts. and upwards. Upon examination, these tailings showed no free gold or amalgam after panning, but on regrinding the coarse particles, there was no doubt about incased gold, which, of course, cyanide solutions were powerless to deal with, owing to not coming in contact with it. A change of screen in this case brought down the value of the tailings by 2dwts., and the cyanide residues to under 1dwt. This, I think, proves the necessity of screen experiments when starting any new mill, as undoubtedly the physical conditions of the ore varies even on the Main Reef series. I need hardly remind you that all gold caught in the mill means 100 per cent. actually recovered, and not 75 to 80 per cent. only as it does if it leaves the mill in the form of tailings. With the erection of

SLIMES PLANTS

the dread of sliming has vanished, as slimes can be treated nearly as cheaply as sands, and with just as good an extraction. The duty of all connected with metallurgy, more particularly mill and cyanide managers, should therefore be to work together in the interests of their various companies. The want of this co-operation has been (as I have overwhelming evidence to prove) the loss of many thousands of pounds in the past. To the mill manager I may offer golden advice—that is, when his colleague tells him he is crushing 6½ tons per stamp against your 5 tons, show him your 92 per cent. recovery from all sources, as against his 80 per cent., and what does this mean on a dwt. rock—50 per cent. more is required to pay expenses, so the 80 per cent. means a profit of 12s. per ton, whereas your 92 per cent. shows a profit of 17s. 8d. per ton. Our motto should be: the mill and cyanide plant are the recovery works. Let us, not I (remember the organist), do all we can to get, not necessarily the maximum extraction, but rather the highest possible profit.

MR. JOHN YATES'S PAPER.

The features of the auriferous banket beds of the Rand are such that there is no reason to apprehend that their extent to the dip is very limited; on the contrary, the evidence available practically places beyond doubt that they will continue in depth far beyond a point where high temperature will render mining operations impossible. Where is this limit of work as fixed by temperature likely to be? Mr. Seymour has informed us that specially conducted experiments have discovered a rise of 1° Fahr. for every 203ft. of vertical depth. If, therefore, we assume that the average temperature at a depth of 1,000ft. is 72° Fahr., that the maximum air temperature in which men and boys can do a shift's work is 100° Fahr., and that this corresponds, say, to the rock temperature of 125° Fahr., we find that the limit of work by temperature is 12,000ft. vertical, so that unless we are favoured with a series of up-throw strike faults—a not unlikely contingency—the pegging of claims more than four miles from the outcrop will probably prove a waste of both time and money. In the headings and rises the difference between the temperature of the rock and that of the air is not likely to be so great as that mentioned, owing to the less perfect ventilation, and for these, at a depth of 12,000ft., compressed air or other means of cooling the atmosphere would be needed to create a bearable temperature. In shaft sinking, the temperature limit would also be less than 12,000ft. vertical; the imperfect ventilation and the presence of a crowd of men and boys will probably make it 7,000ft. — a limit which, of course, could be extended by supplying the sinkers with cooled air—but it is open to question whether men and boys will be easily found who will sink vertical shafts to a depth of even 7,000ft. In view of the fact that the practicability of working at a depth of 5,000ft. is not infrequently questioned, the idea of working to a vertical depth of 12,000ft. will, I am afraid, be generally regarded as too visionary to call for serious discussion. The idea of seeing miners at a depth of 12,000ft. shivering in a cold draught is at present calculated to raise a smile; but things are moving so fast, and so many impossibilities have become possibilities, that it takes a venturesome man to predict what things we are not going to see in the future, and no matter how much the probability of reaching 12,000ft. vertical may be doubted, the possibility of the thing cannot safely be ignored in the laying out of our next deeps. It is not unlikely that our third row of deep level mines will have vertical shafts of about 5,000ft. Between these shafts and the 12,000ft. vertical limit there will be 14,000ft. of reef as measured on the line of dip, assuming the latter to be 30° and the formation undisturbed. Owing to the enormous cost and the difficulties attending the sinking of very deep shafts, together with the possibility of heat limiting the maximum depth of verticals to 7,000ft., I take it that it is improbable that more than one row of shafts will be put down south of the 5,000ft. series. In order to discuss this I will now assume that it is practicable to put down a 9,000ft. vertical shaft, that the third row of deeps, with their 5,000ft. shafts, have 8,000ft. of reef measured on the dip, the reef leaving the property at 9,000ft. vertical, and that from this to the 12,000ft. vertical limit constitutes a fourth row of deeps with 6,000ft. of reef on the line of dip. Present operations have placed the prospects of 5,000ft. deeps practically beyond doubt. But it is not likely that a 9,000ft. shaft for the fourth row is going to be started without some positive evidence of the value of the ground at that depth. Calculating on the present rate of sinking in the stiffer ground of the Central Rand—rates which will undoubtedly be improved on in the future—the sinking of the verticals and inclines of the third row of deeps would take:—

	Months.
5,000ft. vertical, at 90ft. per month ……..	55·5
8,000ft. incline, at 100ft. per month ……..	80·0
Total …………………….	135·5

whilst to put down a 9,000ft. vertical shaft—assuming it is possible—on the fourth deeps, to reach the same point, would, allowing 75ft. per month, take 120 months, or practically the same time; in other words, the reef of the fourth and final row of deeps can be reached and opened up as quickly by the verticals and inclines of the 5,000ft. deeps, as by vertical shafts sunk within their own boundaries—presupposing that there is no material upthrowing of the reef by revere faults. This is favourable to working such fourth deeps through the shafts of the thirds, or, to go a step further, to having the third row of deeps work to the heat limit, opening them up in a manner comparable with the claim area, and thus have the full number of stamps allotted to this area dropping much sooner than would be

the case if the claims were divided into independent third and fourth deeps. The total length of incline working to the heat boundary through the 5,000ft. shafts would be 14,000ft., so that winding in four stages in this distance would probably suffice and constitute a satisfactory working arrangement. Doing all the hoisting through the 5,000ft. shaft would be a little more costly for power than having the 9,000ft. vertical for the lower section of the reef, inasmuch that the ore from this section would be pulled 8,000ft. along the incline instead of 4,000ft. vertical, but against this there would be the saving of wages and of maintenance due to there being one shaft instead of two. There would appear to be nothing simpler than one stage rope hoisting, and about 5,000ft. is apparently the present limit for this, so that by having shaft of this depth, with one stage hoisting, we apply the maximum of power direct, thus avoiding some of the loss connected with the transmission of power to motors underground. Before proceeding further, I would like to touch upon what we may see on these deeper levels regarding the relation of the number of shafts to the number of claims and stamps. The great expenditure, both capital and working costs, which the shafts will entail will compel us to keep their number down to the lowest possible limit. Now the number of shafts in the undisturbed ground is influenced mainly by the requirements of the law, by ventilation, hoisting capacity, underground tramming, the time taken by the men and boys to reach their working places, and capacity for development. The law permits of any property having but one shaft, provided that this is connected up with another. Let us see, therefore, whether one of these contemplated 5,000ft. shafts is adequate for working, say, 1,000 claims and supplying 400 stamps. Take the 1,000 claims to be a rectangular block extending 11,900ft. horizontally to the dip (to the heat limit), and 5,000ft. along the strike. The distance between this shaft and that of an adjoining property similarly laid out would be little less than a mile, and the longest tramming and drive would be about half a mile. The ultimate length of the incline shaft would be 14,000ft. To supply 400 stamps, each underground shift would have to number about 2,000 men and boys. Allowing 70cub.ft. of air per man per minute and an air velocity in the down-take section of the shaft of 1,500ft. per minute, I find that a bratticed shaft 38ft. by 7ft., inside timber, would serve both as downcast and upcast for the 140,000cub.ft. of air needed per minute. With large fans placed in the intake, both at the bottom of the vertical and on the stations on the incline, with an independent ventilation for each pair of levels by means of supplementary fans, and with a fan on the surface at the upcast, the maintaining through one shaft of an adequate supply of air even at the extreme southern boundary would appear quite feasible. Further, it must be remembered that the securing and maintaining of very liberal ore reserves for 400 stamps would not call for the incline shafts to be down more than 4,000ft. below a level connecting the two shafts, and that by the time the full milling stage was reached, in about three and a half years after cutting the reef, the two shafts would have sufficient levels connected—ten—to permit of a joint system of ventilation. The first level would be connected in 27 months after cutting the reef, as against the ten to twelve months of some of the present deeps, and if we can carry on a one-shaft ventilation for the latter period, what difficulty is there in the way of extending it to the former time, more especially seeing that the ventilation will be a mechanical one, and that with fans, &c., there is no very great difference between ventilating a 2,500ft. drive and one of half the length? During the 23 years out of the 26 years of its life, after cutting the reef, the property would really be a two-shaft proposition in everything but hoisting. In the matter of development, the width of the property influences the capacity of the shaft. Thus, with the lateral boundaries 2,500ft. distant from the shaft, it would take 27 months to connect, driving at the rate of 90ft. per month, and in this time the incline would be sunk 2,700ft. at the rate of 100ft. per month. Taking the levels as being 150ft. apart, the number of those unconnected would be limited to 18, and the number of development machines driving to twice this, or 36. Therefore, for the development to keep pace with the 400 stamps, it would necessitate each machine opening up only 1,700 tons per month, thus allowing an ample margin even on a 3ft. milling width. I would here point out that placing the shafts but 2,500ft. apart—like those of the present Angelo Deep—instead of 5,000ft., does not increase the ultimate average monthly development capacity of the property, which is explained by the fact that development must wait on the incline shafts. Coming now to the important matter of hoisting capacity, with the 38ft. by 7ft. shaft needed for ventilation, I find that, taking the 5,000ft. vertical section first, if this is divided into five 7ft. by 7ft. compartments — four hoisting and one pumping compartment—that with four 10-ton skips (the same size as in the Red Jacket shaft of the Calumet and Hecla Mine, as described by Mr. Seymour), and an average hoisting velocity of 2,500ft. per minute, each pair of skips would raise 1,400 tons per twelve hours, or 28,000 tons (sufficient for 400 stamps, allowing for 30 per cent. waste being sorted out) for the four compartments in the same time. By continuing this 38ft. by 7ft. shaft on the incline to the heat limit, and having four winding stages, each of 3,500ft. length, with 10-ton skips, and an average velocity of 1,800ft. per minute, the hoisting capacity of the incline would equal that of the vertical, and it would be noticed that by having the skips and velocities stated—the hoisting in both vertical and incline is really in duplicate—one pair of compartments could, if necessary, supply the 400 stamps by hoisting the whole 24 hours. From these considerations it is apparent that there is much that might be urged in favour of working everything below 5,000ft. vertical through shafts of this depth which do not need stage winding, allotting each shaft 1,000 claims and 400 stamps, thus giving the property about 23 years' milling life on the very moderate basis of a 3ft. milling width. Of course, it is likely that there will be isolated cases where circumstances will make it advisable to have the deepest vertical shafts possible, say 7,000 or 8,000ft., when, unless the present quality of ropes is improved upon, stage winding in the vertical will have to be resorted to; but even in these instances it is evident that if the heat and payable limit is going to be at 12,000ft. vertical we will be confronted with the task of sinking and working long inclines merely a degree shorter than those I have been discussing. Coming now to the capital expenditure needed by the shafts of the future, I will take the hypothetical 1,000 claims, measuring 5,000ft. on the strike by 11,900ft. to the dip, and find how the expenditure is affected by working the whole of this area through a 5,000ft. vertical and an incline, as against the working it through two vertical shafts, one 5,000ft., and the other 9,000ft. deep, with inclines. With the first system we would have—

One vertical shaft, 5,000ft. deep, 38ft. by 7ft. (inside timber), at, say, £42 per foot	£210,000
One incline shaft, 14,000ft. long, 38ft. by 7ft. (inside timber), at, say, £30 per foot	420,000
	£630,000

With the second system we have—

One vertical shaft, 5,000ft., 26ft. by 5ft. 6in. (inside timber), at, say, £20 per foot..	160,000
One incline shaft, 8,000ft. long, 26ft. by 5ft. 6in. (inside timber), at, say, £20 per foot	160,000
One vertical shaft, 9,000ft. deep, 26ft. by 5ft. 6in. (inside timber), at, say, £32 per foot	288,000
One incline shaft, 6,000ft. long, 26ft. by 5ft. 6in. (inside timber), at, say, £23 per foot	138,000
	£716,000

The magnitude of the figures is such as to arrest attention, but dividing the sum by the number of claims gives only £700 per claim, which compares favourably with the £600 of some of the properties at present working. The enormous sums, however, which will have to be spent on the mines of the future to bring them to their full milling stage—sums of £800,000 to twice that amount—afford food for thought, and incline one to ask whether it would not be advisable to keep a few capitalists on hand. If, now, I take a case where the 1,000 claims, measuring 5,000ft. by 12,000ft., are given two shafts instead of one—each consisting of 5,000ft. vertical and a 14,000ft. incline—I get—

2—5,000 verticals, 26ft. by 5ft. 6in. (inside timber), at, say, £26 per foot..........	£260,000
2—14,000ft. inclines, 26ft. by 5ft. 6in. (inside timber), at, say, £22 per foot ..	616,000
	£876,000

The capital expenditure being thus increased £246,000, or £246 per claim, a figure which would be considerably augmented by the more expensive power installation needed by the two shafts as compared with one. Further, the extra shaft would increase working costs by about 3d. per ton milled for wages alone; to this would be added extra coal, stores, and shaft maintenance. The certainty that the working of the 5,000ft. deeps will result in improved mining methods and appliances being discovered, is of itself a plea for the postponement, for a time, of work on deeper zones, and indirectly favours everything below 5,000ft. being worked through the 5,000ft. verticals. Whether the saving effected by giving the block of 1,000 claims mentioned one shaft only, and one mill of 400 stamps, is dearly purchased at the cost of the concentration of hoisting, longer headings, levels and shafts to ventilate, the longer underground tramming, and the risk of trouble arising from disturbed ground and complicated workings, is a matter on which there may be a difference of opinion; but as this saving amounts, in the case of substituting two shafts, to over £700,000, and in the case of substituting over four shafts (two of them lower deeps) to over £2,000,000 for capital expenditure and working costs connected with the sinking, equipping, and working of the shafts—exclusive of interest—during the life of the mine, it is not a point for hasty decision. In these cases it is assumed that the 1,000 claims are given one mill of 400 stamps. If, instead of this, two independent ones of 200 stamps each are erected, the capital expenditure per claim and the working costs will be still further increased. But if the magnitude of the interests at stake calls for an excess of caution in the laying out of the work, even at the expense of increased capital charges and working costs, then would not three 5,000ft. shafts—one central one of 400 stamp capacity, and two side ones, each of 200 stamp capacity—placed about 3,300ft. apart along the strike, quite suffice for two such properties as are mentioned (each with 400 stamps and 1,000 claims) and fully meet the case? The following table, showing the effect the disposition of the shafts will have on this ventilation, is of much interest:—

Ventilation.

(A) Size of property: number of claims.
(B) Number of shafts on property, all verticals being near the north boundary.
(C) Distance between shafts.
(D) Number of stamps.
(E) Number of levels being stopped and used as air connections.
(F) Velocity of air current in shaft per minute.
(G) Velocity of air current in levels per minute.
(H) Depth of the vertical section of the shaft.
(I) Total length of incline shaft. Dip 30°.
(J) Maximum number of stoping breasts which the air comes in contact with, before reaching the upcast shaft.
(K) Time required for the air current to travel the total length of downcast shaft—both vertical and incline.
(L) Time required for the air current to travel the levels.
(M) Total time.

	(A)	(B)	(C)	(D)	(E)
A	5,000ft. strike, 11,900ft. to dip, 1,000 claims.	5,000ft. strike, 11,900ft. to dip, 1,000 claims.	5,000ft. strike, 11,900ft. to dip, 1,000 claims.	2,500ft. strike each, 5,950ft. dip each, 250 claims each.	
B	1	1½	2	1	1
C	5,000ft.	3,333ft.	2,500ft.	2,500ft.	2,500ft.
D	400	600	400	200	200
E	15	15	15	15	15
F	1,500ft.	1,500ft.	1,500ft.	1,500ft.	1,500ft.
G	1,000ft.	500ft.	500ft.	500ft.	500ft.
H	5,000ft.	5,000ft.	5,000ft.	5,000ft.	8,500ft.
I	14,000ft.	14,000ft.	14,000ft.	7,000ft.	7,000ft.
J	48	24	24	24	24
K	12 2/3 min.	12 2/3 min.	12 2/3 min.	8 min.	10 min.
L	10 min.	10 min.	10 min.	10 min.	10 min.
M	22 2/3 min.	22 2/3 min.	22 2/3 min.	18 min.	20 min.

Note.—In cases A, D, and E, each property is assumed to have a joint system of ventilation with an adjoining property, on its east or west boundary, laid out on similar lines. In case B one shaft is common to two properties.

COAL CONSUMPTION IN MEN-OF-WAR.

[42750.]—The consumption of coal in the vessels which are supposed to form our first "line of defence" is attracting a good deal of attention, for though the actual consumption is not a serious matter in the ships that patrol, so to speak, the coasts, it becomes a serious matter in the case of vessels which have to traverse long distances, and may find themselves short of fuel when a long way from a coaling-station. The subject is one that the advocates of oil-fuel should take up, and, if possible, induce the Admiralty to make further experiments. The following remarks quoted from the *Engineer* may give some idea of the absence (or, rather, want) of knowledge on the subject:—

A striking inconsistency is easily found between the statements contained in the letters written by special correspondents of our daily contemporaries on board warships during the manœuvres, now happily ended, and the official reports of trial-trip results which are somewhat irregularly placed before the public. To judge from the first, our ships of war are "coal-eaters." Their furnaces are insatiable. A thousand tons of coal are burned almost as soon as they are put on board. Bunkers are only replenished to be emptied. According to the last, on the other hand, our ships of war are

eminently economical. The coal burned per horse per hour falls far below 2lb. Indeed, 1·8lb. seems to be a by no means exceptional though truly excellent result. Can the two statements be reconciled? We doubt it. We can only persuade ourselves that the truth lies half-way. The economy obtained on a trial trip is not likely to be secured in regular work at sea; we need not stop to explain why. On the other hand, the newspaper special correspondent does not seem to realise how enormous is the work done. We do not blame him. Anyone who has seen coal train after coal train run alongside a big liner, and the contents of the multitudinous trucks transferred to her bunkers, may well fall into the error that she is uneconomical, and so the landsman may easily be misled about our warships. Let us suppose that her Majesty's first-class battleship *Spitfire* works up to 10,000I.H.P., and that her engines require 2lb. per indicated horse-power per hour to keep them going. This means 20,000lb. per hour; or for 24 hours nearly 215 tons. If we add to this some 30 tons for electric lighting, condensing, and auxiliaries, we have 245 tons per day as a respectable total. This is a very large quantity of coal, and involves no more than four days' full steaming for not a few of our big warships. Anyone not familiar with the facts, if he finds that a ship which has emptied a considerable collier three days before, already begins to look out for a port where she can refill her bunkers, may not unnaturally say she is a "coal-eater."

Economy of coal on board warships is no doubt of very great importance, and we fear that the Admiralty statements about it are likely to be innocently misleading. After all, it is not a question of so many fractions of a pound of coal per horse per hour. That is only a means to an end. What is wanted is the end. For how many hours can a warship run at 12 knots, or 14 knots, or 16 knots, without refilling her bunkers? The manœuvres ought to tell us this. If they taught nothing else they would be worth the money, for it must be understood that the answer to the question involves sundry large issues. We have not only the engines and boilers to consider, but the propellers, and, indeed, the whole complicated locomotive machine called a battleship or a cruiser, as the case may be. Of course, it may be admitted that steam-engine and boiler economy is of the first importance, but, after all, they are only a part of the whole; and it is not news that the most economical machinery does not always give us the most economical ship—that is, if economy is stated in terms of $\frac{\text{knots} \times \text{speed}}{\text{coal}}$. Possibly this statement may be confirmed or refuted by the results of the manœuvres. Let us hope that they will not only be published, but published soon, while the interest is fresh and vivid. No doubt the facts will be made public abroad. Why not at home?

Commodore Melville's contribution to the *Proceedings* of the Institute of Naval Architects bears strongly on the matters we are discussing. It may, perhaps be well to explain that, notwithstanding his title which denotes executive rank, he is chief of the Bureau of Steam Engineering of the United States, holding a position akin to that of Sir John Durston in our own Navy. This, of course, imparts all the value extended practical knowledge and almost unlimited opportunities for acquiring information can convey. Commodore Melville argues in favour of three engines and three separate propellers. English engineers will hold that the additional expense and complication involved are so great as compared with twin screws, that very powerful arguments must be advanced and driven home before the triple screw can become in the least acceptable. Commodore Melville gives accordingly certain curves which promise considerable things, and he goes on to say that he does not base his advocacy on these alone. He writes:—"It appears to me that these curves, drawn as they are to give the fullest advantage to the system of twin-screw propulsion, develop fully the superior efficiency of the triple-screw system for full-power trials; or, indeed, wherever all engines are in use. However, as Sir William White says, the matter of the propulsive efficiency of the propellers is but one of the desiderata to be sought in the design of a naval vessel. I submit, however, that the superior propulsive efficiency of triple screws is an element of considerable advantage in their favour, although it must by no means be considered the deciding one. The deciding point in this matter seems to me to be the fact that naval vessels do at least 90 per cent. of their cruising at speeds below 16 knots. In vessels of the fast type, now so universally prevalent, the condensation in the low-pressure cylinders is enormous when the ships are making these low speeds."

It may be said that we are discussing not the cruising performance of our warships, but their full-power work. This is not so. The newspaper correspondents write about ships not going more than half or three-quarter speed, and Commodore Melville takes us back to the old question: How shall we get fairly economical results out of machinery much too big for its work? Two methods have been proposed. One is to use six cylinders for twin screws, and when cruising to disconnect the forward three cylinders altogether, and drive with the three after cylinders only. The other is to cut off the low-pressure cylinders altogether, and use the other two "compound." Commodore Melville advocates the use of three engines and three screws. Whether the power required is full, two-thirds, or one-third, the result, as far as each set of triple-expansion engines is concerned, will be the same. It can be worked to the best advantage. We have the drag of one or two screws to consider, but on this point he has had something reassuring to tell his hearers:—"The trials of the *Kaiserin Augusta*, which were conducted with great thoroughness, measured accurately the drag of the screw, and also the resistance of the rudder, the latter being at a speed of 14·1 knots, considerably more than twice as great as the drag of two idle screws when one of the wing engines was used alone."

All reasoning, however, is apt to be specious when the reasoner strongly favours some particular scheme, and we are, from the perusal of Commodore Melville's arguments, not converted to the triple-screw scheme. We are very far from being certain that the advantages claimed will compensate for its disadvantages. Indeed, if the triple screw is to be used at all, it seems that it would be necessary to make the two wing screws feathering, which might perhaps be less objectionable than any clutch device. We lack information, however, on one point. There is some way of working an engine at less than full power, which is more economical than any other way. Has this been ascertained? What is it? and is the method used in our Navy? The great cause of expensive cylinder condensation has hitherto been supposed to consist in over-expansion. Too early a cut-off takes place; and there is next to no steam in the low-pressure cylinder. In this theory there are gaps, to one of which at least we may refer in a moment. Meanwhile we may suggest that one way out of the difficulty lies in letting down the initial pressure by throttling, and keeping the cut-off constant. But the gap in the theory to which we have referred is that there is no obvious reason why the presence of little or no steam in the low-pressure cylinder should cause waste of steam in the other cylinders. If the third cylinder does no good, it does no harm, and may be regarded at the worst as an extension of the waste pipe to the condenser.

But Commodore Melville puts the whole case in a new light. He tells us that direct experiment has shown that cylinder condensation is a constant quantity, bearing no relation other than one which is accidental to the weight of steam passing through the cylinders; and he puts it as 1lb. of water per hour per horse calculated on the maximum power of the engine. Now let us take the case of a set of engines indicating 10,000H.P. at full speed, and using, say, 18lb. of steam per horse per hour. Of this 1lb. is condensed to waste in the cylinders, or 10,000lb. per hour—that is to say, one-eighteenth of the steam is wasted. If now we run at 5,000H.P., the loss by condensation being still 10,000lb., we waste one-ninth of the steam, and at 1,000H.P. the waste rises to ten-eighteenths, or 55 per cent. of all the steam entering the cylinder. Possibly Commodore Melville will not push the proposition quite so far as this; but at all events we have the definite statement that condensation does not depend for its amount on the quantity of steam passing through the cylinders. If this is true, then the case for the big engines becomes worse, and a very important point comes up for consideration—namely, What is the most economical piston speed?—because the speed for a given power settles the surfaces in the cylinders to be heated and cooled. One more point deserves passing mention. The Admiralty have decided on raising the pressure in warships to 300lb. on the square inch, and to go yet higher if it conduces to economy. But is not this a mistake? It is not when working full power that our ships burn too much coal. It is when they are cruising. Yet it is just at such times that high pressures and great ranges of expansion become very objectionable. How are the two conditions to be reconciled?

Here we must leave a most interesting subject. We have said, we think, enough to show that the special correspondents with the fleets, and the chief engineer of the United States Navy, have given us something to think about.

There does not seem any reason why 300lb. or higher pressures still, should not be used if economy can be gained that way; but the question arises, Are these very high pressures so very economical, taking all things into consideration? **E. R. A.**

THE BICYCLE RECORD AND TRAIN RESISTANCE.

[42751.]—The interesting account of the bicycle test ride behind a train, which you published on p. 548, No. for August 4, has called forth many comments, and some of them may be instructive reading. Thus in the *Locomotive Engineering*, N.Y., which is edited by Mr. Angus Sinclair, a gentleman who knows all there is worth knowing about locomotives, I find the following remarks which have special reference to the resistance of locomotives and the wind:—Bicycle Murphy rode a mile behind a Long Island Railway locomotive in 57 seconds. The track on which the bicycle ran was smoothly planked between the rails, and the end of the car was flanged outward at the sides, upward at the top, and downward at the bottom to within a few inches of the rails, to shield the rider from atmospheric pressure in front.

Nearly every person has observed the partial vacuum formed at the rear of a fast-running train, and its ability to pick up and carry with it for a short distance, scraps of paper, leaves, and even pebbles in its vortex. It was the purpose of this flanged end to increase the partial vacuum ordinarily made, and thereby draw the rider along. Thus it will be seen that as long as the rider kept in the vortex—where there was practically an absence of pressure in front, and atmospheric pressure behind him—he would be pulled along with little or no expenditure of muscular energy. The rider's task, therefore, was not to propel his machine as fast as the train ran, but was to keep in the vortex and move his feet sufficiently fast to prevent them from impeding the revolution of the pedals. As an athletic achievement, therefore, Mr. Murphy's performance is absolutely valueless, and becomes instead a feat of reckless, foolhardy daring, akin to bridge-jumping, should be classed with it as a misdemeanour, and likewise be made punishable.

Had Mr. Murphy, for any reason, failed to keep in the vortex, and been obliged to drop back further behind the train, he would probably have encountered the whirling, eddying currents rushing in to fill up the partial vacuum, and been caused to wobble out of his course and over the rails, which would mean certain death at that speed. This was probably anticipated by the promoters of the event, who stood on the platform and quickly hauled Murphy aboard the train the moment the finish line was crossed.

Murphy's ride has been given undue importance by some of the newspapers, one of which says:

"There is no doubt that in the construction of fast engines of transportation hereafter the problem of minimising atmospheric resistance by sharp-pointed steel prows in front, or otherwise, will be considered as carefully as is now considered the question of minimising the resistance of water in constructing the hull of a racing ship."

Although prettily expressed, the quotation shows a lack of knowledge of railway conditions. It assumes that head atmospheric resistance is the obstructing factor to high train speeds, and asserts that such hindrance is as serious a retardation to locomotives as water is to a ship. Confessedly, it is much easier to drive a locomotive through the atmosphere than a ship through water; hence, there is not the same necessity for a pointed front to a locomotive as there is for a sharp prow to a ship.

The Paris, Lyons, and Mediterranean Railway of France made very exhaustive trials of pointed prows for the front end of their express locomotives, and great advantages were anticipated in the reduction of head atmospheric resistance; but in practice it was demonstrated that there was no perceptible difference in the air-resistance offered by a pointed cone and a flat smokebox front.

Were the head atmospheric resistance minimised, there remains the wheel flange-against-the-rail resistance, which, when a side or quartering wind blows, becomes a far greater retarding factor than a head atmospheric resistance can possibly be. This is proved by the experience of our prairie railroads; and, conversely, the flange friction on curves is taken advantage of by the calculating engineer to assist in retarding the train with his air-brakes when descending mountain grades.

If our lay newspaper friends themselves believe and know no more than that which they write on this subject, they would profit by looking more closely into modern railway operation; for therein will be found a number of greater and more serious drawbacks to very high speeds, which will have to be combated before we finally revert to head atmospheric resistance, and seek to remove it by designing sky-rocket-shaped locomotives.

TELESCOPES, &c. — REDUCING INTENSITY OF LIGHT. — α LYRÆ. — β ORIONIS.—THE PERSEIDS.—PHARAOH AND HIS FELLAHEEN.—A FLY PROBLEM AND ANOTHER.

[42752.]—May I add a few further remarks to my reply to "Pauper et Exul" (42662). I should not certainly join in an indiscriminate outcry against "dealers." There is one firm, at least, of those who advertise in the "E. M." from whom I have experienced the utmost courtesy and every assistance in providing myself with the best telescope that my small means could afford. If "Pauper et Exul," or anyone else in his position, likes to send me his address I will tell him which

firm it was. The telescope was old-fashioned, and very cheap indeed; but the object-glass was good and sound, and with a little (very little) extra expenditure of money on one or two additional eyepieces, and a bit of ingenuity in adapting other arrangements—e.g., the turning the altazimuth mount into an equatorial, I find myself in possession of a most efficient tool. Of course, *as I received it*, except for a pretty good object-glass, the instrument had not much to recommend it to one who could afford a better one. There was only one eyepiece—an old Kellner, power 40. But I had two others which, when fitted to the tube with a sliding adapter, gave powers of 150 and 250 respectively, and I got one of 86 made by a Newcastle optician, besides which I so modified the eye-end of the instrument that, when required, the eyepiece of finder would slide in, giving power 28, with extra large field (about 1° 15'). Thus I have an almost ideal set of eyepieces for a 4in.—i.e., 28, 40, 86, 150, 250. It is a very bad plan to leave selection of eyepieces in the hands of the dealer. A much better plan would be to buy the telescope without any, and get them made by some good optician to order. In ordering an eyepiece, too, I never ask for such and such a power, but either specify required equivalent focus, or foci of eye and field-lenses of each eyepiece. Thus I am sure of getting pretty nearly the power I want, and by measuring focus of field-lens it is easy to check the accuracy with which your order has been carried out. As formerly pointed out by Mr. T. K Mellor in the "E M.," half-focus of field-lens is the equivalent focus of eyepiece, if an ordinary Huyghenian. Consequently, ratio of focal length of object-glass to this half-focus of field-lens is equal power of eyepiece.

I thank Messrs. R. J. Ryle and S. B. Gaythorpe and "U." for their replies, *re* Reducing Intensity of Sun's Light. I also have found that nearly every eyeshade of the common form which I have ever examined had the pimple in the centre referred to by Mr. Ryle. I used to get very good views of solar phenomena with a 2in. telescope, using a terrestrial eyepiece, power 40, with an ordinary eye-shade; but even this suffered after a time from the "pimple," which interfered with good definition. I intend to try the plan of a coloured glass placed at *inside* end of draw tube, and will let your readers know the result. Mr. Gaythorpe is right: It was in Chambers I met with the statement about perforated stops. May I ask for the opinions of your astronomical readers on one or two other matters, which I have met with recently. Both Webb ("Celestial Objects," p. 160) and Denning ("Telescopic Work," p. 308) state that the great American refractors fail to show any companions to Vega nearer than the well-known one. Last year I had the privilege of an evening with the South Equatorial at Dunsink Observatory (Cauchoix famous object-glass 11¾in. aperture) and, observing Vega, I could see most conspicuously a second *comes* nearly as bright as the first. I estimated the pos. angle as ± 295°, and distance from Vega about half that of the other. I do not think it could have been a "ghost."

Again. What is the colour of Rigel? Denning says pale yellow. To my eyes it is as white as Sirius, Vega, Altair, or α Cygni—exactly the colour of an electric-arc lamp unshaded, and, except for diffraction rings, very like one when viewed in the telescope. I should like to hear the opinions of some others on the subject.

I must have been unfortunately placed for seeing the Perseids. Many correspondents report a good display. Here during the week ending August 14, the nights were for the most part clear, and I was at the telescope till about 12h. each night, but the meteors seen were few and small, and most of them not Perseid. May I remind your correspondent who theorises upon the relations established by Joseph between the Pharaoh and his subjects, that in Gen. xlvii. 21, instead of "he removed them to cities," the Septuagint and Vulgate versions, the Samaritan Pentateuch, and Knobel, Olshausen, and Dillman read "he made slaves of them"—a portentous difference of meaning, but one turning on the very slight difference between the letters Daleth and Resh in the Hebrew original. The testimony of the Septuagint and Samaritan agreeing is very weighty evidence on account of their antiquity, the one dating 200 to 300 B.C., and the other very much earlier, whilst we are not at all certain that the Massoretic text from which the English Bible is translated is at all times to be relied on in minute points dating so far back.

I do not think "W. J. G. F." (42703) has got the right sow by the ear (or fly by the leg). Try again! If the fly were outside, just over the carriage roof, or 100ft. above it, how would it be?—or if it were inside and the carriage without a roof? As to his other problem—the blow of the bullet against one end of the cylinder will be exactly equal in force to the reaction of the spring against the other end, so that (except during the infinitesimal interval between release of the spring and the bullet striking) no motion whatever will result.

Wm. F. A. Ellison.

Monkwearmouth, Aug. 22.

UP "DEVONIAN," G.W.R.

[42753.]—Referring to Mr. Walkey's letter (No. 42697, p. 15) I should like to ask Mr. C. E. Stretton, who has repeatedly stated in "Ours" that Rule 145A is rigidly enforced, whether he does not consider that Warren ought to have been fined for his splendid piece of driving between Didcot and Reading, in gaining six minutes in 17 miles upon book time? Moreover, he had the shocking audacity to come into Paddington 2½ minutes before time!

Oystermouth. Scorpio.

FLYING CRAFT MADE PERFECT.

[42754.]—To all men who take the least interest in this extremely important problem—the navigation of the air—Mr. Wilson's sketch (p. 17) of a proposed flying-machine must be very interesting and suggestive. To me it is especially so, as it proves that he—like me—has recognised the inevitable as regards the safety of the flying-machine of the future. I repeat here what I stated in my letter of August 4: it's by gravitation alone that we shall get safety in the air, and by no other means whatever. Mr. Wilson and myself quite agree again on another very important point in dividing the lifting power, whatever it may be. In Mr. Wilson's case it is screws; in my case it is wings. This is, I would point out, extremely important, and of great significance as well; for it points most definitely and unmistakably to the fact that we are slowly but surely advancing towards the desired end. We are at last settled on the right track, and the goal can not be missed. To Mr. Wilson, I think it will be of some interest, when I say that for this last 37 years I have had ideas of flying-machines by the score, or rather by scores, come under my notice by mechanics of all nations—Russian, Australian, German, French, American, and last, but not least, English, ancient and modern. But Mr. Wilson's design is the first that has contained the least semblance of the element of safety, and I for one heartily congratulate him on breaking the record in this line, so far. But at this point my praise must end, and I will, with Mr. Wilson's permission, point out the serious faults contained in this, despite these same faults, best, far and away the best, design for a flying machine ever published to the world. In pointing out the first, and in every respect the greatest, fault, I must again refer to my letter of August 4. In that I remarked we must follow nature in principle always, and in form where we can, or words to that effect. Now, to anyone who may study the subject closely, it will be seen Mr. Wilson has not done this, as the bird uses, first and most important, the mechanical principle of the paddle (double-acting); second, and next in importance, the screw (also double-acting); third, and least of all in point of importance, the aëroplane. Now, if we look at the sketch we see at a glance that Mr. Wilson has made the totally unpardonable mistake of leaving out the paddle, far and away the most important of the three, and thus crippled, his machine will be asked to imitate the bird. Is it likely that it will ever do it? The bird has life—the machine has not; the bird has instinct—the machine has not; and yet the machine is treated less generously than the bird. How can we, any of us, hope to improve on nature in this fashion—to even dream that we can improve on the handiwork of that great Power that designed the wondrous mechanism of our own bodies, is, to say the least, showing a sad want of thought and common intelligence. At the same time, I do not for a single moment expect Mr. Wilson or anyone else to make a perfect flying-machine right away. A perfect flying-machine is not going to spring up in a day. I don't pretend to say mine will be a perfect machine; but what I do say is this. I claim boldly before the world that my flying-machine will, when it comes forth from darkness into the light of day, contain the germs of a perfect flying-machine. It will be built on the principle that every flying-machine that may in the far-off future ever leave this solid earth will be built upon. No matter how beautiful it may be made, no matter how grand the lines, or how bright and harmonious the colours, or how splendid may be the interior fittings and arrangements, they will one and all be built on the very same principles that will be embodied in my little rough machine, because, as (referring again to my letter of August 4) I have already said, there is only one way that the work can be possibly accomplished upon. I cannot make a perfect flying-machine; but I claim this much, honestly and fearlessly before all men, that it is possible not only to fly safely through the air with a machine that shall be made in accordance with the principles of nature, but also to carry unlimited weight about from one part of the world to another, through that thin, unstable, yet powerful element. Having said this much, I will proceed to point out in detail the true reasons why Mr. Wilson's machine will never fly twenty miles through the air. Let us, for the sake of argument, say that the screws would act on the air with sufficient effect to lift the machine into the air. The first thing we should find would be that it was perfectly unsteerable, except when going either dead against the wind or in direct line with it: in any other direction it would be unmanageable, as the wind would act the same on the rudder that it would act on any other part of the machine—namely, blow it with it. We must bear in mind a sailing ship at sea has two elements to help it; we shall have only one, and that a very unstable one at times, while at others a very strong and turbulent one. Again I would fain point out to Mr. Wilson that the aëroplanes, placed where they are, will be a great source of danger. My plan is to leave out the aëroplanes altogether. At first we can get on better without the principle of the aëroplane than with it. We can introduce that later on when we know more of our machine; but let no man make a mistake on this important point. The double-acting paddle we must have.

Thomas George Challis.

[42755.]—Mr. Desmond (letter 42673, p. 580) is quite right when he says that the whole secret of flight lies in ⅛in. These two small appendages called balancers (the baltares of Linneus) are not unlike two pieces of flat hair ⅛in. long, with a ball at one end and jointed to the body of the insect at the other end. Then comes the perplexing problem. When these balancers are hindered or interfered with in their vibrations or removed, the insect at once falls to the ground—in other words, the steering and balancing actions in the act of flying are effectively destroyed. The size of the knobs or balls varies from the diameter of a lilliputian pin down to fractions of that size, and from ⅛in. in length down to fractions in the very small insects, and the weight from the 500 hundredth of a grain to almost infinite fractions of that weight. Within these dimensions, incredible as it may appear, is inclosed the whole secret of the problem of flight; but, fortunately for aëronauts and students in connection with the subject, there are only two classes (the Diptera and Hymenoptera) that withhold the secret so effectually from us. These balancers are found under the wings, and vibrate in their natural recess nearly at right angles to the body. There is no doubt that their functions are to act as dampers of the vibrations of the wings, and of governing the balance in the different phases of change of plane of the wings in the action of flight. I find in one of my notes a statement "that the wings and balancers always move or vibrate in unison." But this cannot be true, for if only one be removed flight is not destroyed, but only when the two balancers are stopped. Although it makes violent and audible exertions, it can no longer fly, not until the balancers are again set free, and yet we can with impunity clip off two-thirds of the wings without destroying the steering or balancing actions, thereby showing the excess of lifting power is two-thirds of its own weight possessed by the insect. Again, it is a very common sight to see two flies flying (like one) together. If by some means (too long to describe here) we stop or destroy the wings of the upper one, on being released or set free the under one will carry its mate on its back in a protesting and triumphant manner. We have again, in this case, the evidence of the fact that it carries twice its own weight almost vertically—yes!—and steers and balances itself and load out of reach, and, if out of doors, to a great distance. Naturally, the inevitable question arises: When that balance is destroyed, can it be restored? We reply: Yes, it can be re-established artificially. (I will explain how it is done later on; and I believe I am the only one who knows how to do it). As to the statement that insects move their wings 100,000 times while birds give one flap of the wing, that is another of those many erroneous assumptions that disappear in the light of investigation. In the instrument figured in the Report of the Aëronautical Society for 1870, the tracings of the wing never exceeded 200 per second, although it was striking all the time for freedom. My own observations are that a fly, say, a bluebottle, basking in the sunshine on a cold morning, and flying leisurely across a ray of sunlight, moves its wings at a very low rate of speed, so low as from 8 to 12 vibrations per second, and travels from 2 to 3ft. in the same time. In fact, one can see every stroke separately, and mentally count the number in a given time; but these can no longer be counted or seen when the insect is disturbed, and, if alarmed, the number of vibrations may rise to 80 per second, and travel 10 or more feet in the same time. Almost from the first of my studies of the subject I perceived the fact that the problem of flight was more of the nature of the balancing tricks of the rope-dancer or the equilibrist or the cyclist, &c., than of actual great power. In conclusion, we have not the slightest doubt that flight can be successfully accomplished at small expense, if capitalists would only come forward and help the investigator and practical man to settle once and for ever the problem of aërial navigation, one of the most stupendous and far-reaching consequences to the civilisation and salvation of the whole human race.

Louis Senecal.

WILSON'S AERIAL SHIP.

[42756.]—A correspondent asks for further details with regard to Mr. Wilson's design on p. 17, of August 18. He will find full details, properly illustrated, of exactly this idea in a book called "The Clipper of the Clouds," by Jules Verne.

Robur.

GREGORIANS AND NEWTONIANS AS TO DEFINITION AND CONVENIENCE IN USE.—NOVICE OR MASTER?—COLOUR OF γ^2 ANDROMEDÆ.

[42757.]—A short time ago your correspondent Mr. Ell. Hay, requested of me the details necessary for the conversion of an 8½in. Newtonian into a Gregorian. A week or two after above request, and, indeed, before the essential parts of the information had time to be given, we find him giving us what we are supposed to take as a carefully-made "practical" comparison of the altered and unaltered forms of the telescope, and this from what purports to be from his own handiwork! By his own showing, he at least made it appear that this was his first experimental attempt at making a Gregorian, and, indeed, in respect to the proper figuring and testing of the small speculum, which he seemed to understand was most essential, he has just but applied for instructions, which time has not as yet permitted him to get—at least, through the medium of your pages. Even if his information has been expeditiously gathered elsewhere, have we not here a most phenomenal case of *expertness* in picking up what is well known to be a difficult part of the business, and of *pertness* in parading the work and conclusions of a learner against those of *experts* of long experience?

Are we, therefore, to take his crude and apprentice-made trials as legitimate evidence of certain points regarding which he goes against theory (indeed, plumes himself on the divergence)?

But while no intelligent constructor takes this view of theory and practice, we find even Mr. Hay's practice, on which he pins so much faith, totally out of correspondence with that of men who, although not clever enough perhaps to compass the whole art of making a perfect Gregorian (i.e., such a one as should be a fit criterion with which to make trials of comparative excellence) in the short space of a week or two, like your gifted correspondent, have left records to indicate the meaning and the results of every step they took.

Briefly, your correspondent's "practical" (?) conclusions were these:—

1. The Newtonian when altered to a Gregorian had no loss of light.
2. The definition remained unaffected by the change.
3. The expense incurred was the only benefit (?) derived from the experiment.
4. The Gregorian form was found inconvenient to observe with—in fact, a "torture."

As to (1) we may allow his remark to pass, for although personally, in common with many observers, I have found a slight defect in this respect in the Gregorian, Tully, who for this very test made of one aperture (6in.) a Newtonian, a Gregorian, and a Cassegranian, found no difference in light in any one of them.

As to (2) the reasoning, from at least our point of view is most absurd: of two possible conclusions, one is, that he, with all his acknowledged want of theoretical training and practical experience in Gregorian making (a more difficult undertaking than for perfect work, as far as the Newtonian can take advantage of it), manages to make, and that against time, in a "knock 'em off" style, in a week or two, a Gregorian which is *found equal to* the production of a maker acknowledged to be first-class, who worked on the Newtonian model.

Could one wish for better *à fortiori* evidence than the above of what the Gregorian might attain to in excellence when made by competent and experienced hands?

The other possible conclusion is that Mr. Hay's mode of setting about the alteration has to some extent vitiated the large speculum, and that his interference has done more damage to the Newtonian form than to the Gregorian.

No one of any experience will doubt, I think, that the perforation of a speculum of any possible material, subsequent to the figuring of it, will act more or less deleteriously. Indeed, the advice he got from all was in this direction.

Now as to the relative amount of the above vitiation in the effect it has upon the performance of the two forms implicated, the following clearly explains:—With the Newtonian of 60in. focus, a given degree of disturbance of figure will at that distance produce a certain wandering of the rays, which at, say, ten times the distance from the speculum, we need not be told would be ten times greater. But the Gregorian application of the same large speculum does *just this very thing*, for the ultimate union of the reflected rays is at 633in., nearly, instead of 60in., the focus being lengthened by the action of the small speculum. In this way whatever disturbance of image results in the Newtonian is, in our example, ten times greater in the Gregorian. Still, we are told (in 42669) that the definition is equal in both, so that our only possible conclusion from this aspect of things is that the Gregorian conditions must in essence be much more capable than those of the Newtonian of giving a well-defined image, when, even after a disturbance which tells so much more seriously upon the Gregorian, that telescope is still found *equal* to the Newtonian, which theory plainly proves to have suffered much less. Again an *à fortiori* argument, and with either choice of possible conclusions, the advantage remains with the Gregorian decidedly.

But this is not all, for past letters of your correspondent profess ignorance up to that time of the proper Gregorian eyepiece, and we have no indication of his having used in his comparative trials this essential adjunct in suitable construction and perfect adjustment, on both of which, as we all know, so much of the performance depends. My poor belated instructions as to above proved too late for your record Gregorian builder, although I spared no pains to make them full and thoroughly practical, believing, as I then did, that I was helping a *bond-fide* constructor and conscientious experimenter. My confidence was, I confess, somewhat shaken in the validity of the proposed trial, when I found (in 42516) my querist "aiming at" and attempting to measure the speculum hole to hundred-thousandths of inches in a case where he had been told precision of this attempted degree was only of use for theoretical purposes, and his "aimed at" number all the time of *no apparent* relation to the theory. He had been specially told that this diameter allowed of some latitude in actual practice, so that the "aim," after all, did look something like a quiz. His invitation that I should personally inspect his more or less imaginary "Gregorian-Newtonian," which invitation he knows I cannot avail myself of, goes but a small way to remove the opinion I then formed.

The third head—the expense—has nothing to do with the issue, for no true scientist either grudges such expenses or brags of them afterwards.

The fourth head—the convenience or otherwise of the two telescopes respectively in regard to use, and more especially his peroration about the "torture" of observing with a Gregorian, with his authoritative "warning"—may safely be left, I think, to a slight comparison of his particular views with those of a few men whose scientific training, skill in practical optics, and experience in observing may, after all, be deemed at least equal to similar attainments possessed by your eminent contributor, if he will generously allow it to be thought so. In the views I shall quote, and which were indeed promised to "A. W. B. M. D." some time ago, the matter of *definition* is in most cases mixed up with *convenience in use*, and my quotations are not necessarily in any particular order as to date, &c.

"With regard to the form of reflecting telescope, it is now pretty generally agreed that when the Gregorian ones are well constructed, they have the advantage of those of the Newtonian form. One advantage evident at first sight is that with the Gregorian telescope an object is perceived by looking directly through it, and consequently is found with much greater ease than in the Newtonian telescope, where we must look in at the side. The *unavoidable imperfections of the specula common to both* also gives the Gregorian an advantage over the Newtonian form. The Newtonian telescope was *still inconvenient*, notwithstanding the contrivance (the finder) of Huygens. The telescope of James Gregory, therefore, soon obtained the preference to which, for most purposes, it is justly entitled." — Barlow. (This author was highly skilled in all optical matters, and was also a careful observer.)

"John Hadley, Esq., who was so successful with the Newtonian, appears afterwards to have constructed this form — for a long series of years the Gregorian was *the most efficient telescope*" (i.e., until the achromatic was invented).—Potter. (As a practical maker, besides being a scientist and also a skilled observer, the above author claims respect.)

"It is in great favour with many observers from its *compactness* and the *convenience*."—Parkinson. (Parkinson's treatise on optics is as a recent work, still one of the best in our language.)

"This telescope is found in practice very preferable to Newton's, and in general to Dr. Herschel's whose construction is only fit for very large instruments. In the first place, it is more *convenient* than either; it has *one more solid advantage*, which is this: the specula never can be worked perfectly true, so that the mirrors correct each other, if they are properly matched."—Coddington. (The above is the opinion of the founder of our modern system of analytical optics.)

"One *convenient* form of the reflecting telescope is that of Gregory—this form of the instrument is preferred."—Chambers' Optics (a standard college treatise).

"Another class of reflecting telescope was invented by Dr. Gregory in 1660; *but they were not made till some years after the Newtonian.* The Gregorian reflector is, however, *preferred* to the Newtonian, and is most commonly used."—S.D.U.K. (Above was written by Pritchard, who had a most extensive knowledge of and experience in the use of all manner of telescopes and microscopes.)

"It *is* (not *was*, observe) the construction almost universally adopted in reflecting telescopes of small size," which, being a modern estimate, means anything somewhere under a foot.—Deschanel's "Nat. Phil.") (This is from one of our best modern treatises on the subject, and shows the truth of Dr. Caplatzi's remarks about Gregorians being still much used on the Continent, although the late fashion of resuscitating the Newtonian in England has temporarily caused a difference with our *amateurs* at least.

As the Cassegrainian, so far as observing posture is concerned, exactly agrees with the Gregorian, we may take Dr. Robinson's remarks on the former in the *Proceedings* of the Royal Irish Academy:—

"An error of the large speculum can be corrected by figuring the small one to meet it. This is of much importance in large instruments. I say this from experience. The adjustment of the specula is more easily verified than in the Newtonian. *The observer is near the ground*, hence more easily sheltered, *and he finds his position easier*, while the Newtonian requires a *complex apparatus to support him, expensive and bulky.* Neither is the field of view so flat in the Newtonian."—Dr. Robinson (from *Proc.* Royal Irish Acad).

"The Cassegrainian (or Gregorian) *gives great facility for the location of the observer.*"—Sir G. Airy, Late Astronomer-Royal (from Royal Society Correspondence).

(The mention of Airy's practical preference for the compound over the simple reflector needs no comment, and his theoretical preference is well known.)

"I am at a loss to conceive why Sir J. Herschel thinks a Cassegrainian or a Gregorian will cause such physical exhaustion of the observer. The eye-end is on a *less sphere* than a refractor, and I never heard that the Struves, Bond, or any who use a a refractor find such a difficulty. On the other hand, I know by experience the climbing of long ladders, or even walking up and down stairs, for a long night's work is really fatiguing.—Dr. Robinson (in R.S. Correspondence).

"Sir John Herschel objects to the labour of observing with a Cassegrainian (or a Gregorian); but Struve, Bond—in fact, everyone who employs a refractor, has the same labour, and I am not sure whether moving up and down ladders with all the clothing necessary for a night's work is not more laborious."—The late Earl of Rosse.

(Having had more experience than most observers of both the instruments he mentions, we can scarcely call his opinion in question.)

Rosse's large telescopes, from mechanical necessity alone, short of expense still more lavish than their eminent constructor ventured upon, could scarcely, even with the most modern appliances, have been fitted up in a way suitable for other than the simple reflector in its original form. This is the proper function of the Newtonian. Herschel's predilection for the form of instrument so famously used by his illustrious father we can easily understand and make allowance for.

Lastly, if it be permissible to mention my own poor experience of several years' standing, I may state that I have used all sorts and sizes of telescopes short of giants, but prefer the achromatic and the Gregorian. For planetary definition I have always found the Gregorian excellent, and, when there is light enough, the resolution it gives of minute, close double-stars is also very fine. It is when accuracy as to place is needed that the Gregorian falls short, for it is not well suited for mounting with divided instruments of precision. But still less is the Newtonian. Taylor's new photo.-visual achromatic is, in my opinion, almost a perfect telescope; but for the amateur, it, especially in large sizes, is not to be thought of.

Evidently Mr. Hay does not know how to observe directly at high altitudes—he possibly bends his neck straight backwards. An evening in some of our public observatories would soon put him in the way of observing easily at all altitudes. He mentions the addition of 18in. to the height of his Newtonian stand; but if that stand is of the usual type of such pieces of ordnance, an additional height of 4ft. or 5ft. would scarcly be enough to enable him to get comfortably at his Gregorian eyepiece, without stooping down on his knees in the position in which one looks up a chimney, *à la* the professional sweep. The lowness of Mr. Hay's stand is no doubt the main cause of his "torture," but are not all makeshift plans and "alterations" always of this nature?

Lastly, respecting the remark in 42669 that "I deny having hinted at (*sic*) a yellow and blue star together would result in green discs," I still deny having given in 42048 the slightest ground for that assumption. The answer to his query in 42669, "If the discs are not sea-green, will he explain what sea-green has to do with it?" is this:—With B practically yellow and C a deep blue, and as I

could only use one spectrum place (viz., λ = ·00001908 of an inch) in computing the effect of star colour upon separation, I, as the merest tyro will observe, used sea-green as the mean colour to be computed with—the colour, in fact in which, with a low power, the unseparated pair is seen as a coloured star. After separation one disc is yellow, the other blue, and green discs are not in it; nor is there any mention in my letter of such *visible* discs whatever, either single or double! The sea-green, I fear, is in the eye of the critic—see? H.

P.S.—The above having been written some time ago contains no reference to the kind and flattering remarks of "Balolo," "A. S. L.," and Mr. Stielow. Space prevents my doing more than thanking them at present. I may, however, add that "A. S. L.'s" explanation in 42718 has my perfect concurrence. Lastly, I desire to thank most heartily your eminent correspondent, Dr. Schroeder, for his most acceptable gift of his Gregorian articles in the *Central-Zeitung für Optik und Mechanik*, 1898.—H.

THE MEDIAL TELESCOPE.

[42758.]—INVENTED by L. Schupmann, professor of the Technical School at Aix-la-Chapelle. The difficulties encountered in the construction of large astronomical telescopes for the finest observations have hitherto proved almost insuperable, owing principally to the properties of the materials employed. Though not exactly of the same nature, they affect both reflectors and refractors alike. Specula over 2ft. of aperture suffer in their *form* on account of their weight, imperfect support, and exposure to changes of temperature, as well as from the deterioration of their surfaces. Their principal merit lies in the fact that they give perfectly colourless images. Whilst the refractor is fairly free from some of these defects, it has others not less injurious to really fine and delicate observation. As the chief among these is the coloration of the images they produce, which sadly interferes with good definition. Though various means have been employed for producing *achromatic* objectives, these have not yet proved entirely effective or sufficient for getting rid of the secondary spectrum—at any rate, in *double objectives*. By the employment of three lenses of suitable glasses and radii, it is now possible, thanks to the studies of Profs. Abbe and Schott, of Jena, to construct almost perfectly achromatic objectives, that is to bring together not only the middle yellow and the coloured edge rays, but all the rays from which white light results. Unfortunately, some of the glasses required for this purpose cannot be produced in pieces sufficiently large for constructing objectives of any considerable size; nor are the chemical properties of these glasses stable enough to insure permanent success. Another disadvantage is that they absorb nearly half the light. A third means for producing colourless images is found in the Dialyte—a type of telescope first indicated by Rogers.

Such a type of telescope you obtain by cutting at right angles to the optical axis the *crown lens* of the double o.g., and then to remove the *compound* left of it back to the original focal plane. The effect of thus dividing the objective is that you thereby greatly increase its focal length, because the *half crown* lens does not so rapidly bring the rays to focus as the *whole*. Now here is the improvement introduced by Prof. Schupmann. In his telescope he receives the rays after they have passed through the flint of the compound part object on a *concave* mirror, which returns them to a focus in front of the half o.g., or in the original focal plane. The telescope thus produced partakes of the nature of the reflector and refractor, and this is why he calls it a *medial* telescope. Having ascertained the dispersion of the compound flint-crown part in the daylight, he can, of course, obtain the same dispersion simply with a flint-lens of much smaller size. It is difficult to make the matter clear to the general reader without figures. I have ordered his book, and may be able shortly to supplement this short note taken from a review, with the Editor's permission. The first rough model of the telescope in question was made in 1893. A short time since a properly worked out instrument was obtained by the aid of Messrs. Reinfelder and Hel, of Munich. Its performonces may be seen from the following data:—Aperture 4½in. (12 centimètres), magnifying power 210. Perfect achromatism. Extremely sharp pictures. Double stars like π Aquilæ 1·6" are easily separated. Stars of $\frac{1}{15}$ magnitude, like the companion of α Tauri, clearly visible. The inventor has taken out patents in Germany and the United States of America. Nothing is mentioned about England. A. Caplatzi.

METEOR.

[42759.]—A MAGNIFICENT pear-shaped fireball, with short luminous train of large sparks in straight line behind it, passed over Chorlton-cum-Hardy on Sunday, August 27, at 10h. 10·5m. p.m. I was walking in a south-westerly direction when arrested by the sudden illumination of the surrounding district with a light decidedly more intense than that of full moon. The direction of flight was from N.W. to S.E. When first seen the meteor was near Deneb Cygni, and travelled to Aquarius, where it suddenly disappeared about the Ecliptic without change or noise. I waited five minutes, but heard no detonation. Apparent size was half the apparent diameter of moon, and much brighter; colour, bright yellow; duration of passage, 4½ seconds. Air very clear, stars bright. J. L. Whittle.

THE DELUGE.

[42760.]—GEOLOGY does not enable us to fix a date without a 10, or perhaps 20, per cent. error. It only enables us to say "5,000 or 6,000 years ago." The date in our English Bible, copied from the Latin and modern Jewish, is too short. But they are well known to be artificially shortened by the Rabbis in our first century. My date of 3102 B.C. is, therefore, simply from the Hindoo story of the Kali-Yuga, because it agrees exactly with the Arab date of Abulhassan Kuschiar (Herschel's "Outlines," 926), and with the Samaritan copy of Genesis (the fullest copy, being the only one that gives double entries of all the lives), if we read the generations each half a year longer. The statement that "Shem, being 100 years old, begat Arphaxad" plainly means that this birth was in Shem's 101st year. So with all the others we ought to add, on the average, half a year.

What Mr. Monck calls "the existing text" is not existing for the Greek Church, or any Asiatic people. What he calls my date is simply the commonest date. Again, what he calls my theory of the Deluge is Halley's and Newton's theory. It is not Whiston's at all. He attributed it to a particular comet's approach, not to a comet's downfall on the earth. It is true we have only Whiston's statement that Newton took Halley's theory; but he honestly says that it was Halley's, and not his own. Whiston, we must remember, was Newton's successor at Cambridge by Newton's own choice.

ERRATUM (p. 40).—For "salve-toothed," read "sabre-toothed." E. L. Garbett.

[42761.]—HITHERTO all letters on this subject have studiously avoided any reference to the Creator of the Universe as the probable cause of the Flood. Natural causes cannot explain everything. Let us take the Bible version as written by Moses in chapters vi. to viii. of Genesis. This version was probably written about one thousand years after the Flood occurred, when all were dead who had survived that great calamity. It is very unlikely that the description given in Genesis was handed down through generations until Moses wrote the Pentateuch. It is still more unlikely that he should evolve such a stupendous fiction out of his own imagination, although this latter seems to gain most credit nowadays. It is very improbable that a man of his intelligence should write a fiction full of inconsistencies and seeming impossibilities without making some attempt to explain them or to justify his statements. The very simplicity of the narrative is the most conclusive proof that Moses wrote just as he was inspired to write, without any exaggerations or additions of his own. Now, if we are to believe him, the dimensions of the ark were 300 cubits long, 50 cubits broad, and 30 cubits high. Taking a cubit as 18in., that gives a length of 450ft., a breadth of 75ft., and a height of 45ft. Surely none can assert that that was a small vessel. Can we doubt of its being sufficient to accommodate eight persons and about 200 to 250 pair of quadrupeds (a number to which all the various distinct species may be reduced) together with all the subsistence necessary for their long incarceration? I fail to see where the difficulty of storage-room comes in, for, with three stories to treble the floor-space, there should be room enough and to spare for all that the ark was meant to accommodate. Another point which has caused much diversity of opinion was the impossibility of Noah collecting two of each species in the limited time he had at his disposal. A very reasonable objection if he did collect them; but he didn't. If we refer to Chap. v. 20 v. we shall read as follows:—"Of fowls after their kind, and of cattle after their kind, of every creeping thing of the earth after his kind, two of every sort shall come unto thee to keep them alive." There we see they came voluntarily unto Noah, led thither by Divine guidance, directing their steps in obedience to an impulse not their own, but emanating from the mind of the God who made them. Some sceptical-minded people are sorely perplexed as to where to find sufficient water to form a universal deluge. It might be of some assistance to them to know that there is enough water suspended in the atmosphere to cover the surface of the whole globe to the depth of above 20ft. It may be here remarked that such a quantity of water could not descend in the form of rain to cover the earth in forty days. Perhaps not, if we gauge it by our English rainfalls, but in all probability it fell in cataracts. This is not at all an uncommon occurrence in some parts of the globe. Travellers may form the truest notion of what I mean who have seen those prodigious falls of water, so frequent in the Indies, where the clouds do not break into drops, but fall with the terrific violence of a torrent. Such an abnormal rainfall could very well cover the earth if it continued without intermission for forty days and forty nights. Now, Moses assures us that the waters prevailed 15 cubits—that is, 22ft. 6in., above the highest mountains. If we cannot accept his testimony, let the mountains themselves be appealed to for the truth of this assertion. Examine the highest eminences of the earth, and they all with one accord produce the spoils of the ocean deposited upon them on that occasion; the shells and skeletons of sea-fish and sea monsters of all kinds. The Alps, the Apennines, the Pyrenees, the Andes, and Atlas and Ararat—every mountain of every region under heaven from Japan to Mexico—all conspire in one uniform universal proof that they all had the sea spread over their highest summits. Search the earth, and you will find the moose deer, natives of America, buried in Ireland; elephants, natives of Asia and Africa, buried in the midst of England; crocodiles, natives of the Nile, in the heart of Germany; shellfish, never known in any but the American seas, together with entire skeletons of whales, in various other countries; all of which are a perfect demonstration that Moses's account of the Deluge is incontestably true.

Again, was it some strange freak of fate or a guiding providence that drifted the Ark into the regions of Armenia, a region particularly well calculated for the reception of the patriarch's family and for the repeopling of the world. The soil of the country was very fruitful, and especially of that peculiar locality where Noah made his descent. The region styled Araratia was also very high, though it had fine plains and valleys between the mountains. A country of this nature and situation must, after the Flood, have been soonest dried, and consequently the soonest habitable. And it also seems in an eminent degree to have contained every requisite for habitation.

As modern research proves the truth of these assertions, does it not lead one to recognise the presence of some omnipotent, though unseen, force controlling the destinies of men even now as in the days of Noah? Why is science so antagonistic to religion? Because religion is opposed to natural laws? Surely not, for is not the story of the Deluge supported by the most elementary facts of experience. Yes; and there are others no less remarkable; but it would be an unpardonable digression to enter into them here. This subject, if accorded the depth of thought that it well merits, will prove to be not such a preposterous fiction after all. Leonard Kelly.

THE MOSAICAL DAY.

[42762.]—HAVING had occasion lately to make a study of Chaldean astronomy, I believe I have a good reason for stating that I have found an explanation of that crux of Biblio-scientific controversy—viz., the meaning of the Mosaical Day, as expressed in the first chapter of Genesis.

Considering the primitive condition of science of any kind in those early days, the Chaldeans seem to have been gifted with almost a divine intuition of mathematics, so far as they were able to go with the arithmetical system they had invented. All primitive people reckon by fives and tens; but the Chaldean scientists used fractions (or aliquot parts), for which the decimal system was inapplicable. They therefore established the duodecimal for their calculations. As, however, the decimal was in general use, it was necessary to combine the two. This they did by taking the common denominator, 60 (5 × 12), as their base. Dividing the radius of a circle into sixty parts, and these again into sixtieths, they obtained the minutes and seconds of arc. The radius, as a chord applied to the circumference, divided the circle into six parts, which × 60 gave 360 parts (or degrees). For the measurement of time they invented the gnomon, and as their calculations were all made from the vernal equinox, they divided the daylight—i.e., from sunrise to sunset, into twelve parts or hours, and these were divided by 60 for minutes, and again by 60 for seconds, of time. The whole day was reckoned from the time the shepherds folded their flocks; as the religious Jews do even at the present day. Thus the evening and the morning were one day. The social official year consisted of twelve lunations (355 days). Differences in their measure of time and occurrence of the Equinoxes led them to the discovery of the precession, which they either purposely or ambiguously reckoned at 30 seconds per century. This gave them 43,200 years to complete the cycle. The Zodiac was first started from the Equinoctials and Solstitials (four points). This fell into their system, and was then divided into twelve parts, to which were given the signs; the cycle, 43,200, being divided into these twelve signs gave 3,600 years to each, and these were subdivided into 600 and 60 as measures of astronomal time. Here, then, were two distinct measurements, each having the same denominations. For astronomical purposes they had recourse to a very singular method—viz., that of reckoning

the solar year as one *second* in the life of the universe. The 3,600 years as cosmic *hours*, and the whole cycle of 43,200 years as one *day*. Here, then, I consider is the origin of *the day* as used by Moses in his description of the Creation.

It must be considered that Moses was a Chaldean by descent, that Abraham had lived in one of their principal cities—Ur. Tradition played a chief part in their knowledge of the past, and there can be little doubt that Moses was instructed orally in all Chaldean sciences. He would thus apply the Chaldean method of time measurement, and for his then purpose would naturally use the chronological or cosmic notation. Thus the "day" in this sense would be the cosmic day of 43,200—or 86,400—ordinary years. He might have used this to express the greatest number he was acquainted with, or it might mean indefinite time. Anyhow, the method so far falls in with the reasoning, that I think it might be accepted as a sufficiently good explanation until a better is forthcoming—and so combine the two—i.e., the literal "day" and the cosmical "day," as to obviate the necessity for any further controversy on the subject.

Clapton, N.E. Jas. D. Hardy.

WURDEMANN'S DIVIDING ENGINE.

[42763.]—It would, I feel sure, be exceedingly interesting to many of your readers, certainly at least to myself, and possibly of great use to not a few, if you could kindly supply us with a detailed description of the engine which you figure on p. 31. The brief outline there given serves only to whet the appetite for more. For years I had wished to obtain a description of a dividing engine, and on first catching sight of the illustration in question I was full of expectation, which, alas! was not gratified. I only trust that it may be in the near future. C. D.

SMALL ENGINE.

[42764.]—Mr. Gibson's sketch of a small engine (p. 43) has no explanation that in any way agrees with the drawing. I venture to think 99 per cent. of your readers cannot understand him. Where are the flywheels (plural)? G. A. Haig.

RETURN STROKE.

[42765.]—Perhaps it has not been the privilege of many of "ours" to have seen the return stroke (we read so much about) during a thunderstorm, therefore it may be interesting for them, that whilst I was watching a severe storm, slowly, yet extremely forcible, wending its way down one of our Highland glens, where, owing to the high rocks, the re-echo is too terrible; when it was at a distance of about a mile and a half from me there was a vivid flash right underneath the cloud, and almost instantly there arose from the midst of a cornfield, about 200 yards from where I stood, a brilliant zigzag *spark*, about 20ft. long, and went right up, not so quick but the eye could follow it just for an instant. L. R. C.

A FLY PROBLEM AND ANOTHER.

[42766.]—In answer to "W. G. J. F.'s" question at the end of his letter (No. 42703, p. 16), if no gravity were acting the recoil of the spring would drive the cylinder, say A, backwards for a certain distance (= *c*), until the bullet impinged on the other end, when the blow would bring it exactly to rest at that point. In the case cited, however, gravity would prevent it going quite so far, and the impact would impart a small velocity towards the centre, which, together with gravitation, would carry it (if I am right) exactly to a point $-c$ on the other side of the centre, after which it would oscillate to this distance on each side *ad infinitum*.

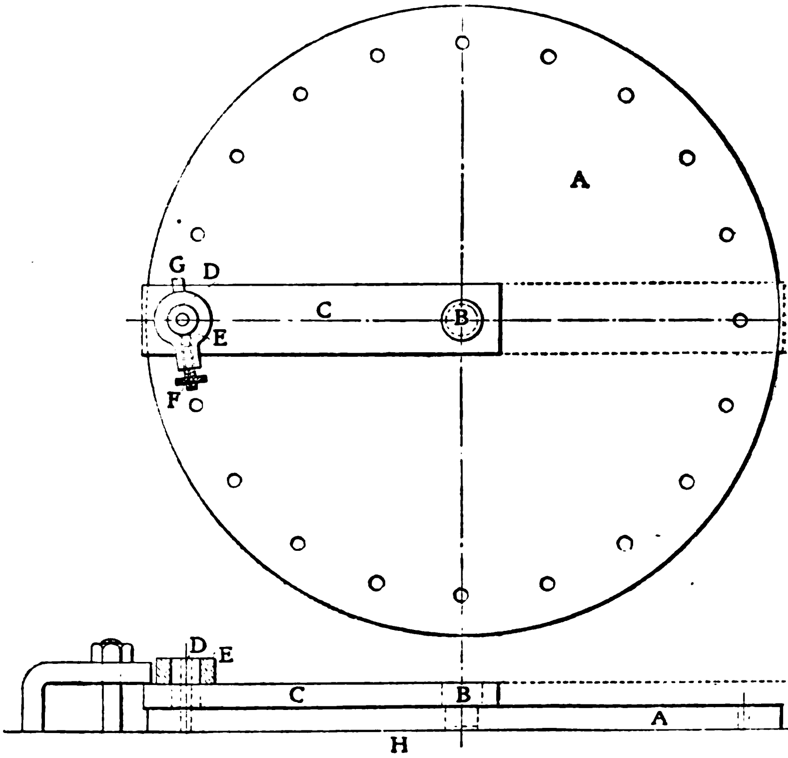
Oystermouth. Scorpio.

A SPACING DEVICE.

[42767.]—Many of your readers have occasion to use a spacing device now and then, and they may like to see the following, which I found in the *American Machinist*, contributed by Mr. C. O. Schellenbach. In his description he says:—

The accompanying sketch shows a spacing device which has recently been used to good advantage for dividing and drilling a number of holes in a circle. It is a simple appliance, and may be of help to those who do not possess a dividing machine. Referring to the sketch, C is a straight piece of bar machinery steel, of sufficient thickness to get a proper bearing for hardened bush, D, the bore of which is made to receive the drill to be used. Bar C is drilled from the required radius to receive pin, B, which is turned to fit into plate A.

A sharp scriber fitting the hole in bush D is now used to mark off the circle of holes. The preliminary spacing is done in the usual way, with dividers, in order to secure the approximate distance from centre to centre of holes. Bar C is then clamped, as shown in elevation. The first hole is drilled; a snug-



fitting plug is then inserted into the hole, and the outer end of adjusting screw, F, is set against the plug, and adjusted until the hole in bush D corresponds with the next division. The bar C is again clamped, and the second hole is drilled. The plug is then placed in the second hole, and the former operations are repeated until the entire circle is drilled.

It will be readily seen that the distance between all holes will be alike, except the first and last hole. These may or may not be alike, as all depends, of course, on the first setting. Supposing that the distance then taken with a micrometer should be $\frac{1}{16}$in. greater or less than the other holes; this would show that the spacing had gained or lost $\frac{1}{20}$ of $\frac{1}{16}$in., or about ·0031, on each hole. The distance is then taken with a micrometer caliper from the end of adjusting screw F to the measuring point G. The adjusting screw is set in or out the required amount, as the spacing indicates. Bush D is then pressed out and a larger bush inserted. This bush should be hardened, the hole lapped, and the bush ground on the outside.

A rose reamer is used for the second operation, and the holes are reamed as they were drilled. The first reaming may not be as close as desired, because of the reamer having more to cut on the side of each succeeding hole. The distance may be taken as before, and a third bush inserted and the holes reamed a second time, as this insures the best results. It will be noticed that screw F is fitted into swivelling block E, which fits snugly to bush D. It is obviously necessary that the measuring points should swivel, in order to keep the measuring screw in line with the chord of the arc. The block E must, of course, be swivelled to suit the number of holes to be drilled. The device shown is only intended for drilling for a given circle; but, if need be, bar C may be slotted and plug B squared to fit the slot and adjusted for any reasonable size circle, and clamped by nut and washer. To use this device for a given number of holes, I would suggest that the adjusting screw be tapped into the side of the bar, as near the bottom as possible, and that the bar be made wide enough to give a broad bearing on the plate. The device is applicable to plates of large diameter, and may be used on an ordinary drill-press.

I forward this rather more to elicit criticism than for anything else, as the device may be well-known to your readers.

Wilmington, Del. J. M.

PRINCIPAL AND INTEREST.

[42768.]—I need hardly point out that interest existed long before the time of Benjamin Franklin, add did not therefore originate with the electric spark from his kite; but I wish to call attention to a few of the consequences of lending money without interest, which I presume Mr. Garbett (p. 579, Aug. 11) advocates. In the first place, I think most persons recollect loans that were made and not repaid, and I suspect that the man who continued to lend without interest would soon find himself short as regards his principal. In the next place, a man might often have occasion—perhaps unexpectedly—to use some of the money which he had lent. He goes to the borrower, who, we will suppose, is honest and solvent, but he has not the money now, and he can only raise it by a forced sale of something belonging to him at an under-value, or by borrowing from a third person. The third person is applied to. He can lend, but not without inconvenience and loss, arising from a forced realisation. He cannot, for example, raise £100 without selling £110 worth of stock at that sum. Naturally he says that if he has to do this the borrower must pay him £110. Is there anything unreasonable in this?

If £1 in a year's time is of equal value with £1 now, then so is £1 in two years' time, in 20 years' time, or in 100 years' time; and a loan of £100 now on condition that my personal representatives are to receive the same sum in 500 years is a perfectly just, fair, and legitimate transaction, in which neither lender nor borrower is unduly favoured.

Let me turn to the case of a retail trader. I suppose Mr. Garbett would allow him to charge more for his goods than he paid for them, since otherwise he would have no means of livelihood. But what about payment? If it is all the same whether I get £1 now or £1 in 100 years, his customers can take their own time to pay, and the retailer may carry on business for thirty years without receiving a single penny. What, then, becomes of his means of livelihood? Perhaps the people who sold him goods, and who supplied him with provisions, clothes, and house accommodation will be as ready to give him credit as he is to give credit to his customers. We should then have universal credit, no Statute of Limitations, and no bankruptcies. I think, moreover, that we would have no payments, for, since payment might be postponed indefinitely without inconvenience, most persons would postpone it for a more convenient season.

Lending or advancing money at an uncertain rate of interest is the same thing in principle as advancing at a certain rate. When I invest money in railway or mining shares the rate of interest is uncertain, because the profits may either increase or diminish. The uncertainty is greater or less with different shares—for example, with those described as Preferred or Deferred. The capitalist generally is in the same position. He advances money at an uncertain rate of interest. His success or failure depends greatly on chance—i.e., on matters which he can neither foresee nor control, and partly on his own skill and energy. He may realise a higher rate of interest than the man who merely invests his money in marketable securities, but he may also utterly fail.

I find nothing in the New Testament declaring this use of capital unlawful. We are indeed in one passage exhorted to lend, hoping for nothing in return; but this evidently refers to charitable loans, and is a form of almsgiving. On the other hand, in the parable of the Talents Ευπορια seems distinctly approved of, and though the capitalist is only acting as an agent, the successful agent is thanked and rewarded by his employer, while the agent who has made no profit is censured and punished. That interest or profit, therefore, should indicate the Mark of the Beast

seems to me in the highest degree improbable. I think, indeed, that our present laws give the usurers too great an advantage, and I gave evidence on that subject before the moneylending committee, which Mr. Garbett did not. But the use of anything must be distinguished from its abuses. W. H. S. Monck.

WHO MADE THE SCREW-PROPELLER A SUCCESS?

[42769.]—In this matter (p. 40) we are simply seeking the facts. To speak from memory when so many years have passed away is apt to mislead.

I therefore send you reprints from the *Nautical Magazine* of 1876 ("The Screw-Propeller"), and from *Engineering* of 1879 (March 5), which perhaps you will be good enough to reissue at your convenience. They speak for themselves, and the several stages of the progress may be verified by any one who desires to do so. Justice.

[We may utilise these reprints when more space is available.—Ed.]

MICRATOMIC ETHER.

[42770.]—The term "atom," which means something not further divisible, has been used to denote the smallest possible portion having the chemical properties of a so-called element. It is not new to suppose that the so-called elements are in reality compounds; and the term "micratom" is here used to denote parts of which such elements may be formed. The term "molecule" may denote a single chemical or element atom or a combination of two or more similar or different atoms.

The term "ether" is applied to a hypothetical medium or atmosphere occupying space, and numerous hypotheses have been put forward, discussed, and even mathematically elaborated as to the constitution and properties of such an ether; it will, however, be at present sufficient to refer to some which have been assumed to be consistent with the undulatory theory of light or radiant energy.

The hypothesis that the ether is a peculiarly perfected jelly cannot be said to have been shown to be probable, notwithstanding the intense imaginative mathematics bestowed on it. The jelly ether is supposed to pervade everywhere—even where matter exists—and to be incompressible and perfectly elastic; but existing knowledge indicates no reason for regarding perfect incompressibility and perfect elasticity as other than incompatible. Any conception we can at present form of elasticity involves the necessity of compression for bringing the elasticity into play. In some mathematical investigations it is virtually admitted that the jelly ether may not be absolutely incompressible; that, however, is an admission that the theory in its present form is imperfect.

To assist in the theoretical construction of an ether, attempts have been made to imagine a combination of rigid, that is, incompressible, mechanical parts and motion, to yield actions such as are due to elasticity, and such attempts show a feeling of the incompressibility difficulty. For this purpose arrangements of the gyroscope, or so-called gyrostat, have been proposed; there is, however, nothing whatever of a resilient or elastic-return action in the gyroscope. If a gyroscope has the position of its axis altered by the action of an external force, it remains with its axis in the new position on the action of the external force being discontinued, and does not return.

Various schemes have been proposed comprising vortices, simple and complex; but whilst the mere idea of a vortex seems to have had fascination, none of such schemes appears to have been, as yet, worked out to a condition of persuasive probability.

Where there are a number of theories to choose from, those involving intense or complex motions, such as those of gyroscopes or of vortices, ought certainly to be rejected in favour of any, if there be any, not requiring such motions.

Apart from the theories of the structure or constitution of the ether, the ordinary undulatory theory of light has been admitted to have difficulties, or at least to be incomplete. In 1853, Macquorn Rankine proposed what he termed the oscillatory theory of light, which he supported with very complete mathematical treatment, and which he believed avoided some of the difficulties of the ordinary theories. He supposed points distributed (presumably uniformly) through space and matter to be capable of oscillating, the oscillations constituting the transverse vibrations of light, and being transmitted from point to point.

The great difficulty with undulatory theories of light is to explain how undulations or vibrations, which are strictly transverse, can be propagated longitudinally, and that at the amazing velocity of 186 miles in one thousandth of a second. It is no doubt this difficulty, as to which scientific textbooks are strangely silent, which is sought to be overcome by the numerous hypothetical or imaginatively created ethers that have been put forward. It is easy to throw a succession of undulations along a string, and thereby illustrate the combination of transverse vibrations with longitudinal propagation; but the string consists of parts, each one fixed to those next it on each side, and if there is no elongation or construction between the parts, the vibration of each part cannot be strictly transversal. The undulating string may serve for a rough illustration, but is not a strictly accurate representation. The fact that sound-waves and waves in water, which consist of alternations of pressure or head, are propagated longitudinally without actual longitudinal translation (excepting to a very limited to-and-fro extent) has no doubt led to the too-ready acceptance of similar views about light undulations. The established fact that tranverse vibrations are concerned in light undulations makes the case extremely different from those of sound and water waves.

Another difficulty of the undulatory theory is how to explain the fact that undulations differing very greatly in wave length and in frequency are all propagated at the same velocity. There are nearly twice as many vibrations in violet light as there are in red light. Towards solving this difficulty no analogical aid is derivable from the phenomena of water-waves or of sound. The velocities of water-waves of different lengths are not the same. Sounds of different pitches—that is, of different numbers of impulses—are propagated at the same velocity; but whilst differences in numbers of impulses does not necessarily imply differences in wave-length, the sameness of velocity implies sameness of wave-lengths.

It is an accepted axion that action at a distance is impossible—that is, that one particle of matter cannot act on another at a distance except through some medium or intervening transmitter or carrier. This axiom has probably, although quite inconsequentially, led to, or favoured, the idea that perfectly void space does not exist, and that a plenum pervades everywhere. It seems impossible to prove or to disprove the existence of perfectly void space, and it is not necessary to do so, in connection with the matters now being considered. Ordinary matter seems to move in the ether as in void space, excepting the actions on it transmitted through the ether; and the particles of the ether, if it consists of discrete particles, may move as, or approximately as, in void space, although something much rarer than the ether may occupy the space. It is imaginable that there may be two or more grades of ethers.

If the ether consists of discrete particles in motion, it so far resembles a gas, and the accepted kinetic theory of gases may be more or less applicable to it. In a gas the component molecules are separate from each other, and are constantly in motion in the space (as we may call it) between them. The energy of the gas consists of the kinetic energy of the motion and of the heat energy or internal motion of the molecules, the latter being the sum for the several molecules of the motions of or between the parts of which each molecule is composed. The condition of things in a gas are complex. There is a continual exchange of heat between the molecules which to some extent takes place by radiation—that is, by means of the ether. There are exchanges by convection—that is, with the heat carried by the molecules in their motions, and by conduction between molecules which come into contact or collision. As a whole the exchanging or transferring of heat between the molecules of a gas takes place differently from the transferring of heat or like energy of radiation by means of the ether.

It has been suggested that the ether is a gas of extreme tenuity, but not otherwise differing from an ordinary gas, and consisting of molecules separate from each other, and darting about in all directions. It has, however, been strongly argued that such a molecular gas, however attenuated, could not be entirely like the ether. A molecular gas may have different temperatures and different states of dilatation at different times. Radiant heat is transmitted through either without any indication of the ether itself being heated—that is without there being changes of internal heat or motion between the parts, of each particle of ether, if such particle has parts. Unless the density of the ether in material bodies differs from what it is outside of them, the density or state of dilatation of the ether is believed to be uniform throughout the universe.

In the micratomic hypothesis, which it is the object of this communication to suggest, molecules or chemical atoms are compounded of different numbers of micratoms, the number being probably in no case very small. This hypothesis tends towards simplification, and not to the complication involved in gyroscope theories, or vortex theories, or contradictory elasticity — incompressibility or jelly theories.

The micratom is capable of oscillations such as are comprised in Macquorn Rankine's oscillatory theory, the oscillations representing radiant heat or energy; but being indivisible it is not capable of variations of internal heat or motion between parts of it. Nor has it what may be referred to as chemical properties, such properties being exhibited only in molecules, and depending on the various numbers of micratoms combined in different molecules. Micratomic ether is thus a kind of gas without those molecular properties of a molecular gas, which, as already indicated, render such gas, however attenuated, incapable of serving as the ether. The micratomic ether or gas may, however, quite well have some of the properties of a molecular gas; in fact, analogy suggests the great probability of such being the case.

According to the kinetic theory of gases, now universally accepted by scientists, the molecules of a gas are continually moving or darting about in all directions. Collisions take place—probably irregularly—and the extents of the movements between successive collisions probably vary; but the number of molecules in even a very small space is so great that the average velocity and the average space or free path, deduced from reasonable assumptions, and from ascertained pressures and densities, are regarded as giving results as accurate as if the velocities and spaces were uniform. Thus the velocity of a molecule of hydrogen has been calculated to be 6,097ft. per second.

Assuming, then, that the micratomic ether is, so far, like a gas, its micratoms will be continually moving or darting about in all directions, their velocity obviously being that of light—186,000 miles per second. The oscillations constituting radiant energy will be communicated from micratom to micratom by the collisions or quasi-collisions, and will, of whatever extent or frequency, be propagated with the velocity of light. In this hypothesis, therefore, there is nothing difficult to understand in the fact that violet light is propagated at the same velocity as red light. Lucretian.

MOTOR CYCLES.

[42771.]—I notice the point is raised about validity of patent for long bolts to cylinder. I believe it was taken out as applied to explosion engines, which, of course, would be a new application of old idea; only advantage in them is ability to use thinner cylinder walls, which is better for lightness and for cooling quickly.

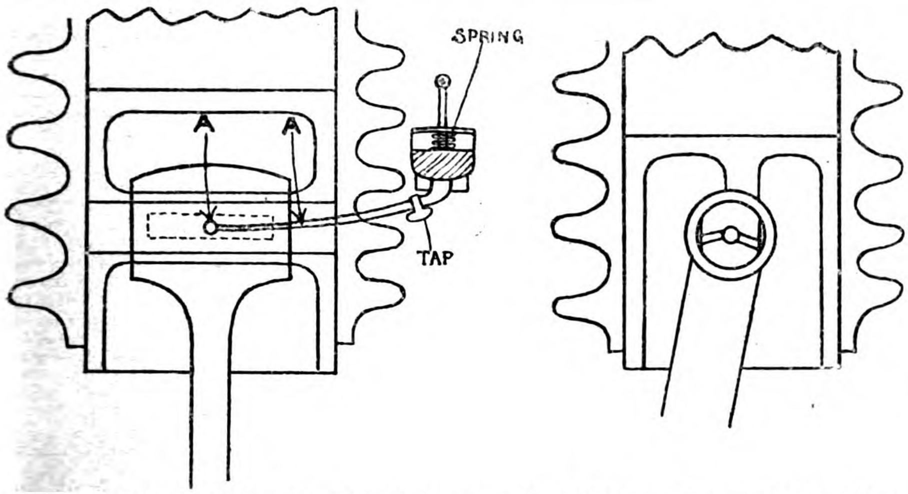
As regards articles appearing, I merely wished to call attention of writer to differences of sizes in two drawings.

I had an opportunity of seeing and examining some motor tricycles last week at Aston. There was a good array, in which some half-dozen prominently figured, and as one is claimed to be an English-made article throughout, I was anxious to compare it with the French-made article. The racing was good, and some exciting finishes resulted in wins for Dion motors, mainly because they were ridden by track experts, and winning machines had special path racing tires, which, for track purposes, had a decided advantage.

This racing, however, is of little use to the general public for judging merits of a machine for road purposes, as people do not want to be summoned for furious driving every time they use machines. I noted some points on these machines some of our interested ones might like to hear about.

The first thing that strikes you is the position of the engine which is placed in the front of the back axle, the makers claiming a better distribution of weight resulting. This was tried by French makers some years ago and given up, the reason being not far to seek. In order to place engine in front everything has to be cut down as narrow as possible, several bad features being introduced thereby, that more than counterbalances any supposed advantage. Having to be kept so narrow, results in valve-gear, cam, and foot having to be placed inside crank-case, one of the flywheels being omitted for this purpose, the side bearings being also cut down to a limit which must be detrimental to their durability. The reason for this is to get clearance for heels when pedalling, also room for chain.

In event of anything happening to valve-rod foot—a common occurrence by the way to all tricycle motors—the engine has to be all uncoupled, taken out of the frame, and crank-case taken apart for a trivial examination. It was owing to trouble of this kind Mr. Stocks was unable to complete his 24 hours record ride, as it would have taken too long to execute repair even had he the necessary duplicate parts. Utility must come first, and with all classes of engines and machinery every part must be made accessible, even though engine may look like a wart on back of tricycle. Again, with engine in front a two-speed gear is next to impossible, as it would come in way of heels so much when pedalling unless frame was lengthened, which would be immaterial in a motor vehicle. A two-speed gear is necessary for anyone who is riding for pleasure, especially in a hilly country like Devon, Yorks, or North Wales. A larger engine would be useless, as present engine, 2¾in. diam. by 3in. stroke, giving 2·25 brake horse-power (actual), is as large as is ever required, and with larger engine vibration would be unbearable. With small engines run at high speed vibration is not so noticeable, then to get power for hills gearing is required. There is one ghastly-looking French attempt that I sincerely hope will not become popular, apparently designed by man in throes of seasickness looking at steam-winches reducing gear on Channel boats.



A, oil-hole shown in front section, with a hole on each side drilled at a slight angle in side section, which come out at two small plates. The ribs are the ordinary things to allow air to cool in cylinder.

In spite of opinion of writer of articles, I think a clutch would be an immense boon riding in traffic, where you are obliged to make a forced stop; after pedalling wearily to start again, the same thing occurs again two minutes after, thus making a fair portable treadmill of a machine intended for pleasure. The carburetter on one machine fills the whole of the front part of the frame, and is divided into three parts—one containing battery, lower part working supply of spirit, and upper part supply of spirit in reserve tank, enabling fresh spirit to be run in when required, a float being provided in lower part to indicate level, the air to be carburetted being drawn in through tube when float-wire works. The mixing valve is on back part of carburetter, of fair size, with gauze for preventing back explosions placed between the two valves, the inlet-pipe being carried direct off side of mixing valve-box to engine being a better arrangement than where inlet-pipe was carried through carburetter and generally contracted in size. This was first introduced in the "Gaillardet" motors some time since and has proved very satisfactory.

The clutch on pedal-gear is placed on crank bracket, which is better than being in axle gear-box, as in latter case, machine has to be wrecked to get at it. Objection is chain running all the time, which is true; but there is little or no work on it, though if not provided with gear-case or chain brush, the dirt is carried right into gear-box, which is decidedly bad.

The differential gear-box and spur-wheel case is of large size, enabling use of wheels of ample proportion, which is a great advantage. The differential gear, or balance, as it is sometimes called, is of the flat spur-wheel type, which is claimed to be easier set and adjusted, and wear better than bevel-wheel Stanley type, the axle being covered with single sleeves, as Stanley's, which looks incomparably better, and is quicker for tightening bearings than the double-bridge pattern. The workmanship on the machine appeared to be first class, the finish of details having a substantial English look in character, which will compare favourably with French, which, though ingenious, with few exceptions is usually of the tin-pot variety. It is satisfactory to see *English* makers are waking up to the fact that within the next few years there will be a boom for motors greater than the cycle boom of a year or two back, and it is to be earnestly hoped the public will not remain apathetic as at present, having the impression generally that by waiting they will get something much better—in what way they do not know, but they will wait until the last minute; and it behoves the English Mechanics particularly to see that when demand comes the motor does not bear the legend "made in Germany," though this is the general way we support home industries.

Monty.

[42772.]—I WOULD like to call your attention to a small detail in the motor cycle now being described, which is, how is the *top* "brass" or steel bush of the connecting-rod going to be lubricated, since it cannot be got at without uncoupling the engine casing?

The designer (as such I take him) says that the crank case must not be filled with oil above. Is it ⅓ or ½, or else the oil will splash on the cylinder walls and cause a stink. This being the case, how is the bush to be lubricated? True it does not want much; but steel to steel, and in the piston it must get pretty hot when running, and of course sing out. This is important. I was cycling in Yorkshire a short time ago, and I came across a "De Dion" cycle, and had a chat with the owner whilst riding.

The engine had the "bagpipes" very bad, and inquiring what was the cause, the rider told me it was the connecting-rod top bush. He could not lubricate it for the reasons mentioned, and said this was the *second* bush, whithin a *year*, which they had sent over from the makers in France, and he would soon want another. The gudgeon, thanks to being the hardest, was not cut so very bad. This, I believe, is the drawback to all vertical machines of this type, and a nuisance, in fact, to nearly all vertical engines, simply because the makers think it not worth troubling about.

I send you a sketch of an idea of my own, previously brought out I suppose. 1st. A mark must be made on one of the cog-wheels, the driver preferably, marked so that the engine can be turned on either the top or bottom centre, exact (the bottom-preferred).

Referring to the sketch, A is an oil hole drilled through the gudgeon to half-way, as shown (front section), about ⅛ diam. or less. It has two holes, one on each side of it, drilled at a slight angle (side elevation), which come out at two small plates (to give the oil a chance), one each side of gudgeon, as shown. Through the cylinder wall, and opposite the hole, there is a brass (or iron) pipe ⅜in. diam., internal screwed. To the end of this (front section) is screwed a lubricator, with a spring attached to piston, something after the type of the "Kingfisher" oil cup, but with this *important* difference—that the piston can be secured at the top of its stroke till wanted. There is also a small tap to regulate the flow of oil. When the cup is filled with oil from the crank case, the tap can be opened, and the piston let loose, with the result that some of the oil gets where it is wanted with a rush, most impact. Otherwise, I think the motor is as complete as it can be, considering the object in view of the designer. This I think is clear enough to your readers.

O. Q. A. Por.

[42773.]—SOME time ago "The Writer of the Articles" was kind enough to say that he would arrange with a respectable firm for making patterns for the engine, &c., which he so ably describes. I fancy that there must be many who, like myself, are anxious to making a beginning, or, at any rate, to have the materials ready for work during the coming winter; and I am sure we should be most grateful to "The Writer of the Articles" if he would put us in the way of obtaining the castings, &c.

R. M. G.

AHAZ'S DIAL.

[42774.]—As the "return of the shadow" on that dial was an event I had the rare good fortune to witness here in England one day in 1848, I may tell "Little Bookham" it had nothing to do with magnetism, as suggested in letter 42721. It was not till many years later that I was aware it had happened. There was no sundial near me in 1848; but the sudden shift of the shadow, forward or backward, about 22½ degrees of our measure certainly took place on every dial in Hampshire that day. It was an atmospheric effect, and I will leave your readers to explain it.

E. L. Garbett.

25, Claremont-square, N., Aug. 26.

POULTRY AND EGG CULTURE.

[42775.]—WITH an "incubator" immense quantities of chickens can be reared with perfect safety if you have a proper "foster mother." You can rear them all the year round with a very little care every day. I have seen eggs hatched in December 1,100ft. above sea-level, and all the chickens lived through the winter in the foster-mother.

G. A. Haig.

REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96154.]—**Dry Cleaning.**—Try with finely-ground starch (rice or potato, not wheat). Brush all dirt out possible; spread on table, and sprinkle starch; fold up into square, powdering liberally between each fold. Put away for several hours, and then open and dust. The starch absorbs grease and dust. Shake well.

REGENT'S PARK.

[96298.]—**Steam Launch.**—I am afraid an answer of sufficient clearness would take up too much valuable room. If the inquirer will publish his address, I will endeavour to assist him.

TRYTOAID.

[96327.]—**Forge Bellows.**—It depends mainly on the nature of the work to be done what sort of bellows is best suited. I fancy that for general work the old-fashioned blacksmith's bellows is best; for a portable forge, the circular bellows or the fan. The querist should endeavour to see the fan at work, and so form an opinion for himself.

T. H. B.

[96328.]—**Flesh-Formers and Heat-Givers.**—See some books written by Dr. Edwin Lankester about the '50's, and works published by J. and A. Churchill, New Burlington-street, W. Mere tables of flesh-formers and heat-givers are not of much use, because their real value depends on what the human economy can assimilate.

T. L.

[96333.]—**A Monkey Puzzle.**—A. Drysdale, p. 43, has given no exact definition of the meaning he assigns to the expression under discussion, unless, indeed, he intends the words of his reply in lines 24-28 to represent his definition—viz., "he must not see opposite sides of it, but he must also be successively at all *points* of a circuit, &c." If this is so, I am afraid he has only fulfilled my forecast; his definition is certainly useless. The word "circuit" is not a scientific term with an exact meaning. Does it include only circular orbits or all closed curves? Must the curves be plane curves, or may they be curves in space, such, for instance, as we might get by slightly distorting a wire circle in a plane outside its own? Further, how can a man who is of three dimensions be "at a point?" The definition is ambiguous. Some of his remarks seem to suggest that he restricts the meaning to cases of revolution in a circle, about the centre of such circle. If so, the man, for example, could not go round the monkey in an elliptical orbit. But when he says "the man could only go round such objects as were in his plane," he makes a meaningless statement. The man, being three-dimensional, cannot be in a plane, nor can he be said to have any plane; neither can the monkey. It is interesting to note that Mr. Drysdale, though he has puzzled himself over the matter, can arrive at no conclusion on the special cases he quotes in lines 15 to 18 of his reply. This alone is sufficient to show that he attaches no exact meaning to the expression. An example of one of these special cases is given by the revolution of the earth about the sun, for the latter body revolves on its axis in about 25 days, therefore, on his own showing, Mr. Drysdale is uncertain whether the earth does or does not go round the sun. Again, he says, "The moon goes round the earth's axis in 28 days." But does this tally with his ideas when we remember that, in a sense, they both revolve about their common centre of gravity? At the end of his letter we read: "The man cannot go round unless he himself is in motion." In motion relative to what points? I would ask. Strict absolute motion is meaningless. Motion is only conceivable when referred to some points considered as fixed. In "terrestrial motions," so called, we consider points on the earth's surface as fixed. In dealing with the Solar System, we assume the sun's centre as fixed, and also some "fixed" star, whose "proper motion" is insensible. In the broadest view of stellar astronomy, where the idea of solar motion is combined with the proper motions of "fixed" stars, we have no theoretical fixed points, and have to assume fixed points on the supposition that the mean of the proper motions of all the stars is a minimum. All this is purely conventional. It follows that when we say A revolves round B, we may (by selecting other fixed measuring points) say, with equal truth, that B revolves round A. As I have said before, Mr. Drysdale may give any meaning he chooses to the expression A goes round B; but, if he wishes to be understood, he must give an exact definition of his meaning. This he has not yet done.

C. P.

[96344.]—**Straw as Stone.**—If the "invention" has been patented, it will be easy to find particulars of the manufacture by obtaining a copy of the specification; but "straw" is in this country rather too valuable, I should think, to convert into artificial stone.

W. B.

[96346.]—**Steamship.**—Query incomprehensible.

The loaded vessel displaces just its own weight in water. Might possibly find some information in Mackrow's work; but it is not clear what is wanted. L. M.

[96385.] — **Electric Fish.** — Thanks to J. McKernan (p. 582). The fish are only flat pieces of tin, and lay on bottom of water-tank, and adhere to ordinary fishing-rod with hook; no wires attached to fishing-rod. How is water charged with electricity? W. H.

[96439.]—**Quadratic.**—To MR. H. S. BURGESS.—In solving "Antario's" equation, I found the roots of the ultimate biquadratic to be:—

$$\pm\left(\frac{1,215}{10,000}\sqrt{-1}\right) - 5\tfrac{3467}{10000}$$

Does this very small cofficient of $\sqrt{-1}$ imply that the equation is anywhere near having four real roots—or, rather, that your quadratic is anywhere near having four real roots?

Oystermouth. SCORPIO.

[96439.] — **Quadratic.** — Thinking "Ontario" may like to have the other three roots of his extraordinary "quadratic," I have amused myself by obtaining them. Taking Mr. Burgess's cleared equation—

$$81y^4 - 720\ y^3 - 9,596y^2 + 8,620\ y + (380)^2 = 0,$$

and dividing by $y - 4$, we get the cubic—

$$81y^3 - 396y^2 - 11180y - 36100 = 0$$

One root of this is found by trial to be—

$$y = 15{\cdot}582241125 \ \ldots\ldots\ldots\ \text{(II.)}$$

Whence by division the quadratic—

$$y^2 + 10{\cdot}69335y + 286{\cdot}017 = 0,$$

and the roots of this are—

$$y = \pm(\cdot1215\sqrt{-1}) - 5{\cdot}3467 \ \ldots\text{(III.-IV.)}$$

where $y = x - 2$. It is curious to note that each of these four roots satisfies one, and one only, of the four forms which the original equation takes as the signs of the radicals are varied—e.g. (II.), only satisfies the form—

$$\sqrt{(x+3)} - \frac{\sqrt{(x-2)}}{\sqrt{(x+3)}} = \frac{11}{3}.$$

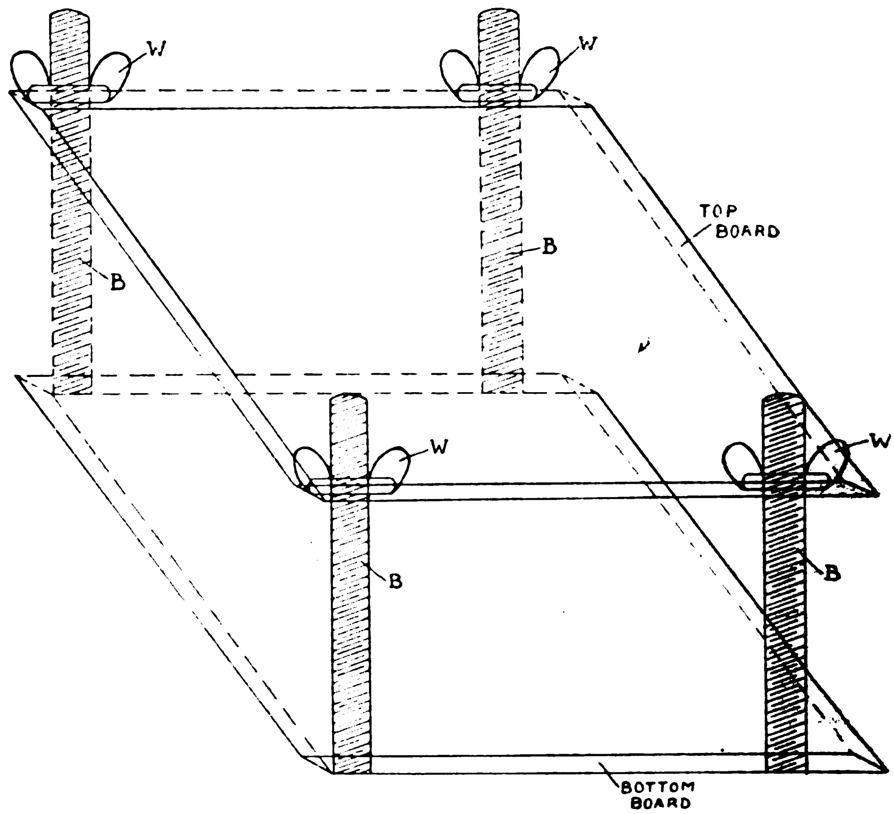
Oystermouth. SCORPIO.

[96446.]—**Saccharin as a Food.**—"With reference to an article in a previous issue on the subject of the use of saccharine and its prohibition in many countries, it should be understood that the prohibition in question is enacted for fiscal reasons only. That saccharine in itself is perfectly harmless is a well-established fact, as it passes through the system unchanged, and that it is an excellent substitute for sugar as a condiment, and is of unquestionable value in certain diseases such, for example, as diabetes and in obesity, as vouched for by many of the highest authorities in this country and abroad."—*Family Doctor*, Aug. 26, 1899. I suspect that answers the question, and may be useful to "Regent's Park." B. D.

[96452.]—**Meal Powder.**—I give extract from an old book which I possess. "To meal gunpowder, brimstone, and charcoal, use a mealing table made as follows: It is of elm, with a rim round the edge 4in. or 5in. high, and one end is a slider, which runs in a groove and forms part of the rim; so that when you have taken out of the table as much powder as you wish, with a copper shovel, you may sweep all clean out at the slider. When you are going to meal a quantity of powder, do not put two on the table at once; but when you have put in a good proportion, take a muller and rub it therewith till all the grains are broke; then sift it in a lawn sieve that has a receiver, and that which does not pass through the sieve, return again to the table and grind again, till you have it all fine enough to go through the sieve." I would not advise querist to make fireworks, or he may find the Excise authorities on his track. I do not think it is allowed in this country. A. DRYSDALE.

[96460.] — **Dissolving Amber.** — I had not noticed that you referred to a special recipe. On turning to this, I find it is from a well-known correspondent. It is just possible that 36oz. of pure spirit would dissolve a little of the 2oz. of amber, if this were previously roasted and powdered; but the result would be no better than if the amber were left out, because roasting takes all the hardness from the amber. The recipes given by our friend are, I am afraid, mostly taken from books, and jumbled together without any practical knowledge at all. S. BOTTONE.

[96462.]—**Wimshurst.**—Thanking Mr. Bottone for his suggestion of reason of failure of paraffin-wax plates, I am sorry to say I cannot attribute my non-success to the causes mentioned by him. In the first place, I have tested the resistance between two adjacent sectors with 200 volts, and this comes out at 210,000 megohms. From front to back of plate, it is too high to measure. With regard to tips of brushes getting insulated with wax, I got over this difficulty by shellacing a path for neutralising



brushes to run on. I do not agree with Mr. Bottone's remarks about hollow glass supports not working, for I know of a machine working perfectly with varnished glass tubes. In my case, I have glass tubes filled with paraffin wax. I think there must be some cause for failure other than those mentioned by Mr. Bottone. G. GREENHAM.

[96467.]—**Inclination of the Pole.**—I have to thank "F.R.A.S." for the trouble he has so kindly taken to supply the useful table of the various inclinations; but if he will please refer to the original question he will see that this does not answer the purpose. What I wanted was some explanation of the original cause of the various angles of inclination. Why are the poles not all at right angles to the various orbits? Bodies thrown off from the sun would have different orbits and different inclinations of their poles according to the distance from the sun's equator; but this is only conjecture on my part. J. R. J.

[96478.]—**Poultry.**—Very common where fowls are confined in small runs. Begin in spring. Caused by pecking at wounds from vermin, generally found round head and neck, and in pecking at nits. Pull feather quills out, watch at some distance out of sight, when the sun is shining, and look for the pickers. When found, remove at once; place in a coop by themselves for a fortnight. If, after they have come out, and still have tendency to repeat evil, place with hen that has had feathers on neck cut short and covered with mustard mixed stiff with vinegar, or other hot substance. The taste of mustard generally cures all but the most inveterate feather pickers or pluckers, and if it fails, kill them at once. Steps to be taken to rid of vermin or nits should be taken. Have prepared powders for the purpose. REGENT'S PARK.

[96469.]—**Indiarubber Stamps.**—In reply to the above query, I beg to say that the class of rubber used for moulding purposes and making into rubber stamps is what is termed "mixed sheet"—that is, pure rubber with sulphur mixed in; and it can be obtained from rubber merchants in various thicknesses. I might state that the method of working the rubber in making the stamp is as follows:—A piece of the "mixed sheet" rubber is first cut out to fit roughly over the mould; the rubber is then slightly heated on one side by holding it against a fire; it is then pressed into the depression of the mould as much as possible (the mould being previously well dusted over with French chalk to prevent the rubber sticking). The mould with the rubber is then transferred to a press, and a simple press for making a few rubber stamps can easily be made by obtaining two square pieces of hard wood, then boring a hole through each corner, and invert a bolt through each corner, and the press is completed. Springs can be put on each bolt to improve it, and wing-nuts, which can then be screwed down with the hand. I inclose a sketch of the press, and shall be pleased to give more details if required. After the mould and rubber is screwed down tight in the press, the rubber, press, and mould is transferred for curing the rubber, which is cured at 145° C., and this can be done by the amateur by contact with a thick iron plate, such as the top of a stove, or in a hot current of air rising from a fire or gas-flame, and to gauge the heat, of course, a chemical thermometer is necessary, that will show high readings, such as 145° C.; but for a small job, however, the proper heat can be gauged by experimenting with small pieces of rubber. Of course, it must be understood that pressure is required when curing, in order that the rubber is forced into all the depressions of the mould. I have described simple apparatus for making a few stamps; but should "G. A. L." or any other reader require any other particulars I will give them the same. W. H. B.

[96468.] — **Indiarubber Stamps.** — A vulcanising apparatus, with lamp and thermometer, such as dentists use, is required for this, and, besides, an iron chase, in which the types are confined. The types are oiled in the usual manner, and the mass is then poured over them. The stereotype plate is not allowed to become dry, but is laid upon a plate of vulcanised caoutchouc. Both plates are then pressed between iron plates, the caoutchouc being pressed in this manner into the stereotype plate. A few sheets of paper are laid between the caoutchouc and the iron plate to prevent the first from sticking to the latter. The whole is then brought into the water of the vulcanising apparatus, and, after the cover has been screwed down, heated to 152° C. (305·6° F.) When it has become cool, the forme is taken from the apparatus, and the caoutchouc is carefully detached. The plate is then cut up so as to obtain the different names, and these are glued to handles. Vulcanising with pure sulphur: Caoutchouc will absorb merely melted sulphur—melts at 113° C. (235·4° F.) It will require a long time before the operation is finished. To hasten, it is necessary to increase the temperature from 150° C. to 170° C. (302° F. to 338° F.), and keep it there for two hours. Not to go much above this temperature, as the caoutchouc acquires hard properties, and not soft as vulcanised. Solvent for rubber: Bisulphide of carbon in connection with absolute alcohol, and anhydrous oil of turpentine. Absolute alcohol made by taking highly-rectified spirit of wine (95 to 96 per cent. alcohol), place in flask previously filled one-fifth full of blue vitriol, which has been strongly heated to pass blue colour to white. This absorbs last traces of water from alcohol, and in doing so gradually assumes its original blue colour, while the alcohol above it has become absolute. Vulcanising with sulphur and mechanical means is by mixing rubber and sulphur by mechanical means, mixture heated to 150° C. and 170° C. (302° F. and 338° F.) If temperature accurately regulated, a homogeneous product is obtained. Kneading rollers also used. Sulphur, in the form of powdered roll or flowers, but with latter, as sometimes sulphurous acid adhere to them, it is necessary to wash them with water and dry completely. REGENT'S PARK.

[96471.]—**Loan Amortisation.**—Referring to my query on this subject, I beg further to illustrate it by the subjoined table, showing the gradual extraction of the loan by the payment of 4½ per cent. interest per annum on 44 years. How does this compare with some of our building societies, as, for instance, above it is stated that for an advance of £1,000, capital and interest is extinguished by a payment of £7 per month for a term of 20 years—i.e., by 240 single payments of £7 each. According to the subjoined table, the difference in favour of the amortisation loan is greater than the whole capital, for whilst this kind of loan only costs £1967·57 in 44 years, an ordinary loan would cost the borrower £1,980 + £1,000 = £2,980, in order to fully liquidate it. X.

Year.	The capital amounts to	In the case of a Loan on the principle of Amortisation, there is to pay:			On the ordinary loan system:	
		On account of capital, 1 per cent. under addition of the interest on the annulled portion of the capital.	Interest at 3½ per cent.	Total.	The capital amounts to	There is to pay interest at 4½ per cent.

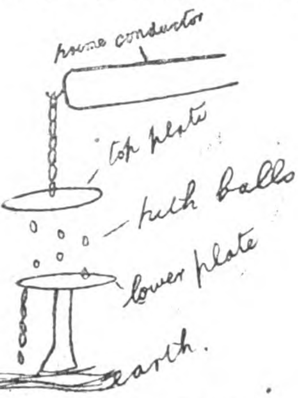
[96479.]—**Bunsen Burner.**—Perhaps data may enable you to judge. Bunsen has two cones, inner one a mixture of air and gas which cannot be kindled, because rate of passage is more rapid than rate at which flame can travel in it. Combustion occurs in outer cone, where speed is diminished. When gas supply to a Bunsen is checked, the velocity of issue of air and gas becomes so far diminished that it no longer is greater than rate at which flame can travel in mixture. Consequently flame passes down the tube of burner and burns at jet from which the coal-gas issues; hence the checked combustion will give rise to much acetylene, detected by its odour, &c. The temperature of the hottest portion of the ordinary Bunsen flame in the centre of the outer cone is stated to be 1,500° C., whilst at the same point in the solid flame the temperature is said to be about 1,600° C. In order to use the hotter flame, it is essential to cover the orifice of the tube with wire gauze to prevent flame from flashing back, &c. REGENT'S PARK.

[96480.]—**Preserving Flying-Fish.** — Solution of alcohol 95 per cent., 8 parts, distilled water 2 parts, makes good vehicle to steep them in. Should have proof alcohol discharged by under part to the interior. May be desirable to remove soft parts. A transparent simple varnish will keep outside right. REGENT'S PARK.

[96482.]—**Insects in Floor.**—In reply to this query of A. J. Scott, I think from his description that the floor he speaks of is infested with dry-rot in an advanced stage, and I might say that the prolific cause of dry-rot is dampness, or dampness combined with warmth, which is a still more active germinating agent than damp alone, the heat being insufficient to evaporate the dampness. The dark stagnant air to be found in practically airless cellars and basement rooms such as he speaks of is just the place to nourish the growth of the fungus. Other causes of the rot are the stagnant air under the floors of the ground—floors where the vegetable soil is not removed, and there are many other causes, all of them in the main being owing to dampness. Stagnant air and bad ventilation is the cause of this. The wood must not only be dry when put in, but must be kept dry if it is to be prevented, and this is an impossibility if the house into which the floor is put is damp, as the air condenses and the wood absorbs the moisture. To exterminate them, as far as I am aware, there is only one remedy, which is to cut away for at least a foot over every part where the fungus is visible. This should be thoroughly done, and all remaining wood, also new wood that is put in, and surrounding brickwork, should be covered with a solution of corrosive sublimate; and great precaution should be used when using corrosive sublimate, as it is a deadly poison, and it is therefore advisable to add a little colouring matter to the solution to show what parts have been painted. I might say that one particular cause of dry-rot is by reason of floors being covered with linoleum, the linoleum preventing any fresh air reaching the floor; consequently the floor and even the linoleum is completely rotted in a very short time. It would take a very long article to describe all the causes of dry-rot and the methods of preventing and getting rid of it; therefore I should advise A. J. Scott to see some practical man on the subject as early as possible, as it is a thing which spreads in all directions (even in the air), and which in a short time plays great havoc in destruction. W. H. B.

[96488.]—**Pitch of Worm.**—Pitch = diameter of pitch circle of wheel, instead of the circumference; it is called the pitch per inch. To find number of teeth in wheel of given diameter and pitch per inch, multiply diameter of pitch circle in inches by the given pitch per inch. To find diameter of the pitch circle to contain a given number of teeth of a given pitch inch, divide number of teeth by the required pitch per inch. Pitch per inch in diameter bears the same ratio to the circular pitch as diameter to circumference. A diametrical pitch of 1in. corresponds with a circular pitch of 3·1416in. To find circular pitch, divide 3·1416 by given diametrical, and to find diametrical pitch divide 3·1416 by given circular pitch. The outside diameter of wheel over top of teeth is found by adding two parts of diametrical pitch to the pitch diameter—e.g., a wheel of 48 teeth, eight per inch pitch, is $6 + \frac{2}{8}$th = 6¼in. diameter outside. The depth of teeth of small wheels usually equals three-fourths pitch. REGENT'S PARK.

[96489.] — **Wimshurst Experiment.** — It is possible that there may be sharp points on the wire which allow the electricity to escape. I prefer a brass chain best. To make pith balls, &c., dance, have two metal plates, one below the other, at a



distance of some inches; connect top with machine and lower with earth, as in sketch. On working machine the balls will dance. I have done it with a roughly made old-fashioned cylinder friction machine, giving 1in. spark. A. DRYSDALE.

[96492.] — **Parachute.** — Possibly data may assist. Gravity: The square of the number of seconds × $16\frac{1}{12}$ = the distance, in feet, a body will fall in a given time. Momentum: The weight in pounds by the velocity in feet per second gives the momentum of bodies. Air is about 840 times lighter than water. The pressure of the atmosphere supports water at the height of upwards of 32ft., or 33ft. nearly. The height of a homogeneous atmosphere is nearly 33 × 840, or nearly 27,720ft. Circumference of cover of parachute about 16ft., with a small hole in the centre to allow the compressed air to escape and prevent oscillation is, I think, usual. Force of gravity near the surface of the earth: Bodies allowed to fall freely, force of attraction being constant, communicates to them equal additions of velocity in equal intervals of time. At the end of one second velocity of body is 32·155ft., at the end of two seconds 2ft. and so, or velocity acquired by falling body is equal to product of time of body's fall in seconds by $32\frac{1}{6}$ft., putting $32\frac{1}{6}$ for 32·155 expressed by equation—

$$v = t \times 32\tfrac{1}{6}.$$

Space described by a falling body in four seconds is equal to the square of the time × by space described in one second. In general, the relation of the space S in feet and the time t in seconds is expressed by equation—

$$S = t^2 \times 16\tfrac{1}{12}.$$

Resistance of a fluid to moving bodies d = density constant, and in places where value of $2g = 64·3634$, and putting K for $\frac{K\,d}{2g}$ it takes the form—

$$R = K\,A\,V^2$$

or—

$$R = K\,A\,(V \pm v)^2$$

Dubuat and others call H the height due to the relative velocity V, or V ± v, consequently—

$$H = \frac{V^2}{2g} \text{ or } H = \frac{(V \pm v)^2}{2g}$$

and putting K′ = Kd give formula as R = K′ A H. Mass in terms of weight. Let λ denote latitude of place, h its elevation above mean sea level, g_1 = 32·1695ft. per second, being value for λ and h = 0, and R = 20,900,000ft., being earth's mean radius, then—

$$g = g_1\,(1 - 0·00184 \cos. 2\,\lambda)\,.\,\left(1 - \frac{2\,h}{R}\right)$$

for latitudes exceeding 45° cos. 2 λ is negative, and terms containing it as a facter have signs reversed sufficiently accurate. g = 32·2ft. per second nearly. Body of weight W acted on by unbalanced force, F, the change of velocity in the direction of F produced in a second will be—

$$\frac{F}{m} = \frac{F\,g}{W}$$

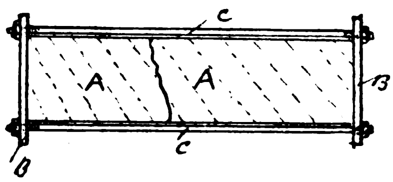
whence—

$$m = \frac{W}{g}$$

m is constant. g and W vary in the same propor-

tion at different elevations and different latitudes. The density of air varies at different distances from earth's surface—e.g., about four times rarer at seven miles than at surface, at 14 miles it would be 16 times, &c. The rarity augments in a geometrical progression, the altitude in arithmetical progression.
REGENT'S PARK.

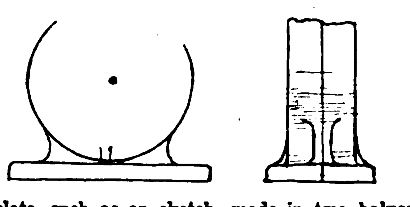
[96495.]—**Oilstone.**—After having tried glue, &c., with very qualified success, I hit upon the following idea: — In sketch, A A represent the



broken pieces of stone, B B are two pieces of ¼in. iron ⅝in. broad, with two ¼in. clearing holes in each, and C C are two long ¼in. bolts. After screwing the nuts hard up, grind the faces of stone on an ordinary grindstone or coarse emery cloth. It is scarcely worth while putting so much labour on a cheap stone; but with a Turkey it is different, and of course if it has broken very obliquely this arrangement is no good. W. EWART GIBSON.

[96497.]—**Magnetic Effects.** — Resistance of metals: Copper 1, gold 1·29, zinc 3·52, iron 6·08, lead 12·29, antimony 22·23, bismuth 82·13, gas carbon 2037·00, silver 0·94, aluminium 1·82, platinum 5·67, tin 8·27, Ger. silver 13·10, mercury 59·55, graphite 1106·00. Conductivity, specific: silver 100, zinc 27·76, iron 15·50, Ger. silver 7·19, graphite ·0852, copper 94·2, platinum 16·61, lead 7·67, mercury 1·58, retort carbon ·0463. Magnetic field: The influence of any magnet extends all round it, so that if at any point the pole of a smaller magnet were placed, it would experience a force varying with its distance from the larger magnet. The fact that the magnetic influence pervades a space is expressed by saying that the space is a magnetic field, the strength that would be exerted on a unit pole at any point being called the intensity of the field. Hence the intensity of the field at any point is measured by the force with which it acts on a unit magnetic-pole placed at that point. In absolute measure the unit of intensity is that at which a unit-pole is acted on by the force of a degree. If F be the force acting on a pole of p units, where the intensity of the field is H, then $F = pH$. Then the unit is the quantity of electricity concentrated at a point capable of repelling a similar quantity of electricity at another point at the distance of one centimètre with a force of one degree, or with a force which would give the mass of one gramme the velocity of one centimètre per second in one second. REGENT'S PARK.

[96501.]—**Oil and Gas-Engine.**—The dimensions are suitable, only you would require a small



bedplate, such as on sketch, made in two halves along with crank chamber, whose bolts would, of course, keep it together. W. EWART GIBSON.

[96505.]—**Lithia.** — Some thirty years ago I had a bad attack of gravel, and, after having been set right by my doctor, I asked him what I could take to prevent a recurrence, in some convenient form for travelling abroad. He advised granulated effervescent citrate of lithia, which I have never since been without. When I have felt any uneasiness about the kidneys, lumbago-like pains in the loins, or rheumatic aches and pains in any part of the body, I have taken, at once, a teaspoonful in a third of a glass of water—a refreshing, pleasant draught—and I feel sure that my life has been lengthened and made much less painful from a timely use of it. One to four doses, at or before meals, have generally been sufficient, though it has been required three times a day for a week on several occasions, to clear the blood. I should never advise this or any other medicine to be taken habitually, in order that its full effects might be felt when needed occasionally. I believe Bishop was the first to introduce this form of medicine, and have always taken his, to be sure of getting a given quantity of lithium. I presume there are other reliable makers, but advise the querist, as I have done many before, not to purchase the article loose, but in a bottle, with a reliable maker's seal to the cork, for once I got for citrate of lithia at a druggist's a similar-looking article which was proved by analysis to contain "not a trace of lithium."
EDWARDS.

[96505.]—**Lithia.**—The natural alkaline waters of the celebrated Neuenahr Spa are considered very effective. They can doubtless be procured through chemist's stores. Write for English prospectus to "The Direction" of the Spa at Neuenahr, near Remagen on Rhine, Germany. X.

[96505.]—**Lithia.**—Without entering into the question as to whether lithia is really any more efficacious in removing the uric acid tendency from the system than soda or potash, &c., it may be broadly stated that the best mode of administration is in the form of certain natural mineral waters, as, for example, Huel Seton water (Cornwall), Baden-Baden, Carlsbad, Aix la Chapelle, Bilin, &c. The salt usually prescribed is the carbonate.
S. BOTTONE.

[96509.]—**Resistance Coil.**—To MR. BOTTONE. —Rather an awkward job, since 2lb. No. 22 is about 240 yards long. However, wind your wire in a tight spiral round a ¼in. mandrel, drawing off from time to time what you have spiralised, until you have done the entire length, which will then measure about 16 yards. Arrange this zigzag fashion between the upper and lower bars of a square frame (which should be faced with slate), stretching it slightly between studs on the upper and lower bars. Put terminals at each end. A ½H.P. windmill will require vanes about 4ft. long. For illustrations, &c., write to Messrs. Duke and Ockenden, millwrights, Littlehampton, Sussex.
S. BOTTONE.

[96510.]—**Coppering Carbons.**—Pitch is very good, and is best applied with a hot iron. It will dissolve in oil of turpentine, but remains sticky for a long time. You will find bicycle enamel better for small, neat jobs. S. BOTTONE.

[96512.] — **Electric Lighting.** — The cheapest and best way is by means of a small dynamo driven either by oil, gas, or steam-engine. Cost of total plant, inclusive of lamps and shades, would come out somewhat as follows:—Dynamo, £2 10s.; gas-engine, £4; lamps, shades, and wiring, 15s.—say, £7 5s. Read my book, "Guide to Electric Lighting," and do not allow anyone to bamboozle you into buying a battery to light your lamps with.
S. BOTTONE.

[96512.]—**Electric Lighting.**—You would do better with a ½B.H.P. gas-engine and a small dynamo. You could then light four or five incandescent lamps. To light only two by a battery of cells would be troublesome and unsatisfactory.
Dudley. WEBSTER MICHELSON AND CO.

[96515.]—**Model Steamer.**—Engines should be powerful enough to drive boat, if the boiler is large enough; but you will not get much speed out of it. Another tube will only increase the quantity of steam generated at a given pressure, and the safety-valve should be a little larger, but no stronger—i.e., it should blow off at the same pressure. A short tubular stuffing-box is only required in addition to the bearings. TRYTOAID.

[96518.]—**Charging Accumulators.**—Proceed methodically. It takes 2·5v. to charge each cell; hence with 6v. you can only charge two in series properly; but as you have 60 ampères at your disposition, you may be able to charge several sets of two in series at once. To know how many, you must ascertain from the makers of the cells what the fair charging is. Suppose you find it to be 12 ampères, then 12)60(5. You could therefore arrange the cells in five parallel sets of two in series. Without knowing the ampère-hour capacity of the cells, it is impossible to say how long they will take to charge; but either by a voltmeter or by a hydrometer, you can ascertain whether each cell has received its full charge. The voltmeter should indicate 2·25 volt, the hydrometer should read 1·19.
S. BOTTONE.

[96518.]—**Charging Accumulators.** — The best arrangement for charging the four [motor-car cells with your plating dynamo is two cells in series 2in. parallel. The voltage required would then be five, and the number of plates in each cell would determine the quantity. The charging must be continued until the solution in the cells becomes milky, and gives off gas freely.
Dudley. WEBSTER MICHELSON AND CO.

[96518.]—**Charging Accumulators.** — Two cells in series is the greatest number that the dynamo will charge; but you can add as many more in parallel as 50 ampères will supply, allowing about 5 ampères for every square foot of positive. For cells in series you, of course, only reckon the area of one cell. For example, suppose each cell contains 1sq.ft. of positive then with two in series you require a current of 5 ampères, as the total current passes through both cells. If, now, you add a second pair of cells in parallel with the first two, the same voltage will suffice to drive the current through them; but the current will be divided between the first pair and the second pair, giving at 5 ampères only 2·5 ampères to each pair —that is to say, the current supplied must be increased to 10 ampères, and so on. It is necessary to have at least 2·5 volts at the dynamo for every cell in series. The time required for charging will be rather greater than the capacity in ampère-hours divided by the charging current. When fully charged the sp. gravity of the electrolyte will have risen to about 1·19, and the plates will gas freely. A fully-charged cell will show a voltage of 2·5, and 1·9 volt is the lowest limit to which a cell should be allowed to discharge to. W. J. G. F.

[96519.]—**Water Power.**—Of course, with the same head the shorter pipe will discharge more water and give more power than the longer pipe. A 4in. pipe 100ft. long with 10ft. head will discharge 341·32 gallons per minute, the same pipe 1,000ft. long with 10ft. head 98·60 gallons per minute. A turbine of 80 per cent. efficiency would, roughly speaking, develop 1H.P. with the shorter pipe, ¼H P. with the longer. W. J. G. F.

[96519.]—**Water Power.**—The velocity of a flowing liquid depending like that of a falling body, on gravitation, a stream issuing 4ft. below the surface of a liquid mass or head, will have double the velocity of one issuing at one foot below the surface. At the depth of 9ft. the velocity will be treble, at 16ft. fourfold, at 25ft. fivefold, and so on, and is independent of the irregularities of friction, &c.; the velocity equals the square root of the depth of vertical column of water. Actual velocity compared with theoretical, as 64 to 100. Head of water in feet × ·433 = pressure in pounds per square inch. Pressure in pounds per square inch × 2·31 = head of water due to pressure. Contents of pipe: square the diameter in inches, result will be weight of water in one yard of pipe. One-tenth of the amount will be number of gallons one cubic foot of water = 62·425lb. One gallon = 10lb. One H.P. = 33,000lb., raised one foot high per minute. REGENT'S PARK.

[96520.]—**Velocity of Light.**—In space this is exactly the same for all kinds of light. Otherwise the eclipses of Jupiter's moons would be coloured. But it is believed that in refracting bodies the colours have some difference of velocity.
E. L. G.

[96521.]—**Speed of Falling Chain.**—This is the way I would attack "J. F. B.'s" problem. Let m = mass of unit length of chain. At the end of the time, t, before the end of the chain has reached the bottom of the pit, let there be a length, s, of the chain in motion, and let v denote its velocity at this particular instant. The chain is leaving the upper coil at the rate of mv units of mass per second, and the velocity with which each particle is being started is V. The rate of generation of momentum in the chain leaving the upper coil is therefore mv^2 units per second. The force or tension in the chain where it leaves the upper coil is therefore also mv^2. We have then a length, s, of chain of mass, ms, acted on by an upward force, mv^2, and by a greater downward force—viz., its weight, mgs. By the second law of motion—

$$\text{force} = \text{mass} \times \text{acceleration}$$

$$\therefore mgs - mv^2 = ms \times \text{acceleration}$$

or— the acceleration $= g - \dfrac{v^2}{s}$

We must now find an expression for the acceleration such that $g - \dfrac{v^2}{s}$ may be equal to it throughout the motion—i.e., at any instant of time. Let a be the actual acceleration of the chain, and then $v = at$, and $s = \frac{1}{2}at^2$.

$$\therefore \frac{v^2}{s} \left(\text{in the expression } g - \frac{v^2}{s}\right) = \frac{a^2t^2}{\frac{1}{2}at^2} = 2a.$$

$$\therefore g - \frac{v^2}{s} = g - 2a = \text{constant} = a,$$

or $a = \dfrac{g}{3}$; or the chain descends with uniform acceleration equal to one-third of that due to gravity in an unconstrained particle. Now—

$$v^2 = 2gs.$$

Substituting— $v^2 = 2 \times \dfrac{32 \cdot 2}{3} \times 580,$

or $v = 111 \cdot 6$ft. per second. In other words, the velocity of the chain would constantly increase until its end reached the bottom of the pit. Thereafter the chain would continue to fall with the constant velocity of 111·6ft. per second. The tension in the chain is at a maximum at the point of departure from the upper coil; from that point downwards it diminishes. D. J. CARNEGIE.

[96523.] — **Water Lifting.** — The simplest, cheapest, and most assured as to avoidance of clogging is by a centrifugal pump driven by the steam-engine. A 3in. c.p. costing, say, £12, including foot-valve and grating, using, in this case, 4in. suction or force pipes, would do the work most effectively. The pipes would cost about 2s. per foot of length, including jointing materials. They must be laid well underground to avoid water freezing; a means for draining them when not in use should be provided. Revolution of pump disc about 1,500 per minute. H.P. required about 5. The pump should, of course, be placed near the engine, and driven by a belt, and the vertical

section height should not exceed 15ft., the pipes having a regular rising gradient from the foot-valve in the pump, and perfectly air-tight. A self-acting check-valve on delivery-flange of pump, with a small outside charging pipe and cock between its upper and under surfaces is advisable.
M.

[96523.]—**Water-Lifting.**—Does "Redburn" require a cheap makeshift apparatus to raise this quantity (p. 46) once, or an efficient pumping plant for raising the quantity at daily or weekly intervals?
TRYTOAID.

[96550.]—**Mensuration.**—Let n = number of sides, r = radius of ⊙.

$$\text{Area of inscribed hexagon} = \frac{n r^2}{2} \sin. \frac{360°}{n}.$$

$$\text{Area of circumscribed hexagon} = n r^2 \tan. \frac{180}{n}.$$

$$\frac{n r^2}{2} \sin. \frac{360}{n} = \frac{6 r^2}{2} \times \cdot 8660 = 2{\cdot}5980\, r^2.$$

$$n r^2 \tan. \frac{180}{n} = 6 r \times \cdot 5774 = 3{\cdot}4644\, r^2.$$

$$3{\cdot}4644\, r^2 - 2{\cdot}5980\, r^2 = 813\text{sq.ft.}$$
$$\cdot 8664\, r^2 = 813$$
$$r^2 = 938{\cdot}4 \text{ approx.}$$
$$\therefore r = 30{\cdot}63.$$

$$\text{Area of } ⊙ = (30{\cdot}63)^2 \times 3{\cdot}1416 = 2947{\cdot}63\text{sq.ft.}$$

Lasswade. J. WIGHT.

[96528.]—**Chemical Action.**—The sodium of the $Na_2Mn_2O_8$ and the hydrogen of the H_2SO_4 would replace one another, forming permanganic acid and sodium sulphate. The effect of adding the mixture to sewage would be to deodorise the harmful products of decomposition.
W. J. G. F.

[96528.]—**Chemical Action.**—When sulphuric acid is added to a solution of sodium permanganate, sodium sulphate and permanganic acid are produced; but this latter splits up immediately into hydrated binoxide of manganese and free oxygen gas. If the above mixture were made previous to its addition to the town sewage, little good would accrue, since most of the oxygen would have escaped in the form of gas. Were it possible, however, to effect the mixture at the time of the addition, it would greatly assist in disinfection.
S. BOTTONE.

[96528.]—**Chemical Action.**—On mixing sulphuric acid with potassium permanganate in aqueous solution, oxygen is liberated:—

$$4KMnO_4 + 6H_2SO_4 = 2K_2SO_4 + 4MnSO_4 + 6H_2O + SO_2.$$

It is impossible to state definitely what would be the exact action of the mixture on the sewage, as it would depend on the composition of the latter, temperature, pressure, &c.; but, broadly speaking, all organic matter easily capable of oxidation would be destroyed, the carbon being oxidised to carbon dioxide, the hydrogen to water, and the nitrogen to nitric acid, which would, of course, combine with the various bases present to form nitrates.

Trin. Coll. Oxon. J. M. W.

[96529.]—**Duffett's Battery.**—Depends entirely on the size of the battery. I have known a three-pint cell to give 2 ampères for 24 hours right off. Yes, there is a good bit of local action; the same cell would be practically spent if left uncoupled for four days and nights.
S. BOTTONE.

[96530.]—**Alternator.**—To MR. BOTTONE.—It is extremely doubtful whether you would get alternators by different makers to run together in parallel. Apart from the question of varying cycles, there is that of the difference of crests and curves. It would certainly be necessary to use a synchroniser. The use of a synchroniser is to ascertain when the machines are running in step with one another.
S. BOTTONE.

[96533.]—**Liquid Fuel.**—Slit sprinklers, in vogue years ago, are stated to be good in their way; have average oil consumption of 6·4lb. per H.P. per hour, and 5 or 7-fold evaporation, according to experiments by Noble and Guleshambarov. However, they waste steam and oil, and best adapted for countries where oil is cheap. Pipe sprinklers have also their admirers; work more economically than slit sprinklers. The first, require 6·6lb. of oil per H.P. per hour, while the latter require from 4·4 to 5·5lb. Consumption of steam much less, not more than 4 to 6 per cent., whereas slit-sprinklers use 6 to 8 per cent. The stopping up of the outlets of the slit sprinklers applies in a less degree to the pipe sprinklers. The principal advantage of pipe-sprinklers consists in the spherical flame which fills up the cylindrical fireboxes of marine boilers better and heats them more equably than does the stream of the slit sprinkler. They save the walls of the boiler, and render, when properly fitted, firebricks at back of firebox unnecessary. Nozzle sprinklers: One of the simplest is that of Sadler's; consists of two small bronze nozzles screwed on to opposite ends of a T-shaped malleable iron pipe. Another T-shaped pipe is screwed into third orifice of the first; the horizontal pipe of this admits the oil, while the perpendicular end admits the air. The steam-pipe, before reaching the sprinkler, is conducted into the furnace, and forms a winding pipe here, through which the steam is passed to get superheated. The oil and air enter the sprinkler through the same orifice and in the space between the nozzles. The furnace is lined with fireproof brick. The oil and steam supplies are regulated by separate taps or valves.
REGENT'S PARK.

[96535.]—**Crucibles for Silver.**—Heat new crucibles to a bright red heat, and throw in some scraps of hard Bohemian potash glass. When nearly melted, smear round inside of crucible thoroughly, and remove surplus glass.
TRYTOAID.

[96536.]—**Crucibles for Silver.**—When desired to prepare crucibles to withstand extremes of temperature, mixture of siliceous sand, ground flints, calcined clay, graphite, or powdered coke. The most infusible prepared from clays containing largest proportion of silica, and in which the amount of lime and oxide of iron is small. Add siliceous sand, graphite, or powdered coke to clay in proportion of one-fifth; if, in the case of the two latter, a larger amount were used, although the infusibility of the concrete might be increased, the carbonaceous matter would be liable to become consumed, and the crucible gradually destroyed.
REGENT'S PARK.

[96537.]—**Electric Lighting.**—To MR. BOTTONE.—(1) Absolutely indifferent; usually put on the positive. (2) No, because the cells take up the excess.
S. BOTTONE.

[96538.]—**Gravity.**—This must be felt instantaneously at all distance. Otherwise, the motions of heavenly bodies would be very different.
E. L. G.

[96542.]—**Nordrach Treatment of Consumption.**—In the *Nineteenth Century Magazine*, for January, 1899, there appeared a paper by Mr. J. A. Gibson, describing his experience as a patient of the treatment at Nordrach, where he remained many months, and where he was restored to health. In the number of the same magazine for February Dr. Coghill, physician of the hospital for consumption at Ventnor, criticised Mr. Gibson's statements, thinking him influenced by gratitude to exaggerate a little, and giving some particulars from his own hospital for comparison. In the March number, Mr. Gibson replies, and gives further information, and many particulars to facilitate the building of sanatoria in this country. All three articles, I think, should be of much interest to a "Consumptive."
T. S. P.

[96542.]—**Nordrach.**—I expect much the same as that of Mr. Just at Pangborn, which consists of curing by natural means—i.e., by bathing, light and air, earth-energy, and a natural system of diet. Here, too, the open-air cure is carried out on an elaborate scale by sleeping in the open, or in partly closed sheds—often, in fact, on the bare ground out of doors; by sun-baths and earth packings, and wonderful are some of the cures said to be effected without anything in the shape of drugs, and for every kind of ailment. Write for prospectus to Mr. W. Just, Pangborn, Post Stapelburg, Harz, Germany.
X.

[96543.]—**Sundial.**—If I were "Nauticus" I should try ordinary cement. I have made two sundials. The dials are made entirely of ordinary cement mixed with fine gravel; when it has dried it is as hard as slate, and then painted with white paint. The styles are brass pins, and are fixed on the dials when the cement is wet. When the cement is dry they are perfectly solid. "Nauticus" might try cement or cement with fine gravel mixed.
TANNER.

[96543.]—**Sundial.**—Melted sulphur and Portland cement are both good. Clear out holes, set pins central, and run with the sulphur or cement.
TRYTOAID.

[96544.]—**Lard Refining.**—Melt by aid of a saline or steam bath in an enamelled iron vessel, and add gradually 1oz. powdered alum and 2oz. chloride of sodium to every 50lb. of fat under treatment. Heat continued above 212° F. until scum ceases to rise to the surface, which contains all the organic and other impurities, and must be skimmed off as fast as formed. Fat then strained through bolting cloth into clean stone jars and left to cool. Next spread on circular stone slab, top surface of which is slanting from the centre, or slightly conical in form, and provided with a stone roller made to revolve by suitable gearing. As the roller or muller revolves over the fat, cold water is allowed to trickle upon it, and this dissolves the saline impurities remaining in the fat. Afterwards the fat is heated until all water is expelled by evaporation. When cold, fat will be found to be very white and pure.
REGENT'S PARK.

[96545.]—**Rubber Rings.**—If the rings are not too far gone, let Mr. Dow soak them in a dilute solution of ammonia (obtained by adding 1 vol. of ·880 ammonia to 2 vols. water) till they become soft. The process is hastened by squeezing them at intervals between the fingers. I can personally recommend this recipe, as I always use it for softening rubber stoppers that have become hard. It is, however, useless if the rubber has become quite brittle. Rubber articles should be stored in airtight tins, or at least in the dark.

Trin. Coll. Oxon. J. M. W.

[96545.]—**Rubber Rings.**—Solvents for rubber: Of 100 parts of rubber in bisulphide carbon 65 to 70 parts, benzol 48 to 52 parts, oil turpentine 50 to 52 parts, caoutchine 53 to 55 parts, ether 60 to 68 parts; softening would take less time. Bisulphide of carbon is very volatile and poisonous. If quantities of rubber are dissolved or softened with oil of turpentine, a simple method is to pour oil turpentine, with about 10 per cent. of its weight of English sulphuric acid, into a well-closed tank, and allow it to stand till used. Sulphuric acid forms sediment at the bottom of vessel, from which can be drawn off the oil turpentine. Instead of sulphuric acid, melted calcium chloride can be used. If rubber in small pieces is placed in boiling linseed oil it can be dissolved or softened; but besides the altered rubber, solution will contain dissolved other products. The machine for cutting up rubber is one with cylindric cutting-drum, something akin to the wood-planing machine. The periphery of the cylinder formed of sharp knife-blades inclined towards the superficies. Rubber (cubes) pressed by a lever against cutting cylinder revolving at high speed shreds the material. To prevent heating of knives or planes a jet of water falls on knives, &c. See W. T. Braunt on "Rubber and Its Working."
REGENT'S PARK.

[96545.]—**Rubber Rings.**—Perished rubber can never be satisfactorily restored, especially when required to stand steam pressure. It can be ground up and mixed with fresh rubber and sulphur to make an inferior vulcanised rubber.
TRYTOAID.

[96546.]—**Motor Batteries.**—Fresh sawdust well moistened with a strong solution of salammoniac, to which a little glycerine and solution of zinc chloride have been added, will start the batteries afresh, provided the carbon contacts are clean and good. Say, salammoniac 1lb, water 5 pints, glycerine half-pint, chloride of zinc ¼lb.
S. BOTTONE.

[96550.]—**Mensuration.**—The smaller and larger hexagons being exactly as 3 to 4, and their difference 813in., this is also the area of one-third of the inner hexagon. Dividing it by $\sqrt{\frac{3}{4}}$, which is ·8660254, we get 938·77154 for the area of a square the radius of your circle. Multiplying this by 3·14159265 gives 2949·2446 for the circle's area.
E. L. G.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

A NEW ice-breaker is expected at Cronstadt for use in that port during the coming winter. It has been built at Abo.

IT is an unexplained fact that glowworms are much more brilliant just before an approaching storm than at any other time.

QUERIES.

[96551.]—**Motor-Cycles.**—I should like to ask if the writer of the articles on "Motor Cycles" now appearing in "Ours" would be kind enough to give us a design for the fore-carriage of a tandem quadricycle, and also steering arrangement for same, before concluding his articles?—AJAX.

[96552.]—**Cigarettes for Asthmatical Patients.**—Can any of your readers inform me how to make the cigarettes sold by chemists for the cure of asthma, &c. If so, I shall be greatly obliged.—W. RITCHIE.

[96553.]—**Astronomical.**—Will some scientific reader kindly answer the following? In solving the astronomical triangle when Lat. is south and sun's Dec. is north, is it not correct to use for colat. 90° + lat. and for polar dist. 90 − dec. Is there any other way giving same result?—JANCIS.

[96554.]—**Magnetism.**—In remagnetising a compass needle of theodolite, can one use a horseshoe magnet or is a straight bar-magnet better? I find a straight bar loses its magnetism.—JANCIS.

[96555.]—**Equations.**—Will a mathematician kindly give a student the solution of the following simultaneous equations?

$$\frac{2}{3}x^2 + \frac{3}{5}yz = 6\tfrac{3}{4}$$
$$\frac{3}{5}y^2 + \frac{5}{7}xz = 7\tfrac{1}{2}$$
$$\frac{5}{7}z^2 + \frac{7}{9}xy = 11\tfrac{2}{3}$$

—J. HARDING.

[96556.]—**Oil and Gas Engines.**—Would someone oblige by telling me what proportion of a motor cylinder's capacity should be left for the compressed gases when the piston is in? Whether there should be a difference when using coal-gas, petroleum vapour, or the vapour of petrol, and why is this particular compression the best?—ISIS.

[96557.]—**Window Cases.**—Will any reader kindly inform me what are the best ferns to grow in a case about 2ft. 6in. in length, also if there are any special methods of treating them?—PARIS.

[96558.]—**Injector.**—Can any reader explain why injector will not force water into boiler when working? It will feed boiler when engine is not working, but when engine is working no water can be forced in with injector. Boiler is 4H.P.—W. H.

[96559.]—**Billiard Table.**—Can anyone tell me how to put a new cloth on a slate table 12ft. by 6ft. with indiarubber cushions?—G. A. H.

[96560.]—**Electrical Work in Australia.**—Can any reader tell me if there is much electrical work in Australia, and could I work my way out? Any hints will oblige—ELECTRIC ENGINEER.

[96561.]—**Perspiring Hands.**—Could any reader state a remedy for perspiring hands, as perspiration interferes greatly with violin-playing?—A READER.

[96562.]—**Lantern Screen.**—Will any reader kindly give hints for making an opaque screen about 7ft. square to roll up? I want a recommendation both of a good fabric to hang smoothly, and of a satisfactory dead-white surfacing material, not liable to crack or fall off.—BOOKWORM.

[96563.]—**Belting.**—Given the diameters and distance from centre to centre of two unequal pulleys. Required, formula to determine necessary amount of driving belting open and crossed.—C. J. CHARNOCK, Sereda, Russia.

[96564.]—**Organ for the House.**—Will some fellow reader of "Ours" tell me if bellows 48in. by 24in. will be large enough to supply wind to a manual organ of six stops and Bourdon pedal, small scale? Great to be 4ft. wood stopped, 8ft. open metal (to tenor C), and a 4ft. metal through; Swell: 4ft. stopped, wood, 4ft. metal open, and 2ft. metal open; Pedal: bottom twelve notes with remainder coupled to Great. Would that be a good specification for a practice organ for the house?—PIPE ORGAN.

[96565.]—**Dynamo for Nickel-Plating.**—I have a dynamo with cogged-ring armature, wound for 50 volts and seven or eight ampères. The fields are wound in four sections. Can I use this for nickel-plating if I run slow, so as to reduce the volts, and connect the four sections of the fields in parallel, so as to reduce their resistance?—ISIS.

[96566.]—**Motor-Cycles.**—I have been very interested in the articles appearing in the ENGLISH MECHANIC on "Motor Cycles." Having a Beeston motor-tricycle, with tube-ignition, I am now thinking of altering it to electric, and should be glad to know if I may expect more power and speed from it when so altered? The gear is 12 and 88, and 26in. wheels. I can travel about sixteen miles an hour; but it does not go so very fast down hills. I think this is because one cannot alter the time of ignition with a tube. I think of having one of Blake's coils and dry cells. Are magneto-igniters any use for tricycles? I also find the oil gets out between the top of case and cylinder. I have not a valve for the compressed air and the gas that gets by the piston to get out, and it seems to me that that forces the oil out. I cannot have valve fitted on the oiling-screw, as I have the tube from the oil-pump or spare tank fitted there. Would a length of ⅜ tube screwed in case, and carried above motor (so that oil should not get out) do? Where should it be fitted to case?—T. L. SPENCER.

[96567.]—**Dry Pile.**—To "SIGMA" or MR. BOTTONE.—Will you kindly inform me whether it is possible to construct a dry pile, in contact with a metal plate, of sufficient intensity to render fluor-spar luminous when dusted on it? If so, will you add how many tinfoil and manganese series would be necessary for the square foot for a slowly-acquired, but permanent, effect (vide Sprague's "Electricity, &c.," 1884, p. 50)? Also, if the effect could be obtained by a substitute for the manganese? We have no "E.M." in this colony.—SIDNEYITE.

[96568.]—**Palms.**—I have a few beautiful palms, and when I take them from the greenhouse into the drawing-room for a few weeks the points of the leaves turn brown and wither, necessitating their being cut off. The room is large, and apparently airy enough for them. Walls and carved work are painted white, with silk panellings. Will any reader of "ours" kindly give their opinion as to the cause, and if there is any cure?—L. R. C.

[96569.]—**Phonograph for Recording Music.**—I have an Edison's home phonograph, and would like to be informed how to take the music of a Burmese band generally consisting of six players. The floor space occupied by them when at play will not exceed 4ft. by 3ft., and yet I cannot get faithful records, the sound reproduced being very low compared to the original. Is a special room necessary to take such records, and if so, please inform me how to make one? Also what machine would you recommend me to produce a much larger sound than that generally given out by a home phonograph?—MG. HPAW, Moulmein.

[96570.]—**Wheat Roots.**—What is the average length of a wheat root grown under ordinary conditions and extraordinary conditions—i.e., where the root travels in search of water?—J. R. J.

[96571.]—**Electro-Motor.**—To MR. BOTTONE.—I have a Siemens H girder dynamo giving an output of 2½ ampères at 25 volts. The armature I have at present is solid, and I intended to replace with one built up of laminations, as the solid seems to get so hot after working some little time. Would it be any advantage to have a tripolar armature in place of the H type? If so, I suppose it would require a three-section commutator. And would the beginning of one coil and the finish end of its neighbour have to be connected to one section of the commutator? Could this machine be worked as a motor, as I wanted to work a grammaphone by motor instead of clockwork, and what battery power would be required? I suppose I should require a resistance-coil to regulate the speed.—E. EVANS.

[96572.]—**Spark Coil.**—Would Mr. Bottone please say if the following would be best for a double-cylinder oil-engine spark coil? Core, 8in. by 1in. diam.; primary 1lb. No. 18, three layers; secondary, 1½lb. No. 32 d s c.; condensor, 100 sheets foil 5in. by 4in.—SPARK COIL.

[96573.]—**Steamy Windows.**—I would be greatly obliged if any of your readers could inform me through your paper of a way in which frost and steam can be kept off windows.—S. WATSON, Toronto, Canada.

[96574.]—**Jets.**—I shall be much obliged to any reader who may furnish me with, or refer me to, proofs of the following facts:—(1) That a liquid column becomes unstable and tends to break up when its length equals π times its diameter. (2) That the state of maximum instability is reached when the length of the column equals 4½ times its diameter.—SURFACE TENSION.

[96575.]—**Small Dynamo.**—Would someone please give full particulars for making a small dynamo to light a four-volt two-ampère lamp? I wish to drive it either by clockwork or by a falling weight, as suggested last week by F. D. C. Baly, on. p. 38. The lamp is to be fixed before a clock, and I want to light it up at nights for about a minute now and again so that I can see the time.—CARLIOL.

[96576.]—**Induction Coil.**—I want particulars of length or weight, and also thickness, of primary and secondary wires for making an induction coil to use for giving a spark for wireless telegraphy, and also a battery to work same? I want a spark long enough to be effective for experimental purposes across a large room.—CARLIOL.

[96577.]—**Seltzogene.**—We have a seltzogene de Fèvre for making soda-water. When the lever at the back is pressed down the soda-water escapes from underneath it as well as from the spout in front. I should like to know how to repair the leakage at the back?—G. G. B.

[96578.]—**Subterranean Topography.**—Has any work been published ever upon the subject of interior cavity and cave formation, and what is the proper term to designate the study of this science or subject?—ESTIGEOLOGY.

[96579.]—**Chemical or Stylographic Paper.**—How is paper prepared which, with a stylo or special pencil, gives indelible writing, &c.? I see in the new invention for printing without ink (where electricity is brought into use) that the paper (printing) has to be previously prepared. I wonder with what chemicals?—SCRIBE.

[96580.]—**Speculum Polishing.**—In the "E.M." of June 18, 1897, there was a letter from Mr. Clarence Stirling, in which he says that he had found out a far superior material to emery for speculum grinding, and that he would give particulars about it in the "E.M." in a future letter. Would some reader of the "E.M." let me know what this superior abrasive is, or the date of the "E.M." in which the information was given?—A. R. C.

[96581.]—**Steam Whistle.**—A whistle 7in. diam. by 4ft. 6in. long sounds a certain note. As a variation in the diameter, I understand, has the effect of slightly altering the pitch, what would be the correct length of an 8in. whistle to give the same sound? I would be glad to have a rule or formula expressing how the relation between length and diam. modifies the pitch.—W. H.

[96582.]—**Medical Coil.**—To MR. BOTTONE.—I have constructed a shock coil as given by you some months ago in the "E.M.," ⅝in. core, 6in. between the heads, and wrapped with No. 28 gauge wire d.c.c. as primary; then insulated and divided into six sections with 1½oz. of 36 gauge d.s.c. in each section as secondary. Please say what battery I shall require and amp. power. I am thinking of using bichromate cells. I should like a good strong shock if possible. Also please say how I am to join up the coils to battery. Must I use the primary coil in series with the others? I have joined the ending of one secondary coil to the beginning of the other and brought to a terminal, six terminals of which are crescent-shaped in touch with a switch. The armature of coil is ⅝in. from end of coil. Is this too far, please? German silver spring 4in. long with platinum contact points.—ALBT. A. HARLEY.

[96583.]—**Tips.**—I have some rods of iron very similar to stair-rods, on the heads or ends of which I want to put a piece of rubber to stop the iron from scratching. How shall I put the rubber on without having an overlapping, and yet be so fixed as to be firm? The rubber to be ⅜in. in width and ⅛in. in thickness.—F. NEWTON.

[96584.]—**Removing Rust.**—I should be glad to know the best way of removing rust from the wrought-iron railings around a vault in a churchyard, which have been neglected for many years and are now badly corroded. The railing-bars and gate-posts are fixed in a stone curb, and the bars are rather light. The design is complicated, so that filing or rubbing would be rather difficult.—FILIAL.

[96585.]—**Motor-Cycle.**—Would the "Writer of the Articles" or other kind friend reply to following? Where should be the position of piston when exhaust commences to open on a Leon Bollée motor tricycle? Should exhaust-valve open as wide as it is possible? Shortening valve-rod opens valve wider, and also opens it earlier. Any other information respecting the working of this motor would be very welcome, as it does not give good satisfaction. The compression is good; ignited by hot tube.—A. TURNER.

[96586.]—**Liquid Air and Magnetism.**—As the properties of liquid air are under discussion, I should like to draw attention to the possible effect of a strong magnet on liquid air, or on the liquid after most of the nitrogen has escaped in the form of gas, such as a liquid containing 70 per cent. of oxygen. Now, in such a liquid the percentage of nitrogen is generally the same in every part of that liquid—that is, the atoms or molecules of nitrogen are equally distributed through the liquid in question. That this is the effect of some affinitive force which is not very strong may perhaps be inferred from the fact that liquid air is sometimes obtained in two liquids of different percentage composition. Now, what is the effect of a strong magnet on enriched liquid air? Are we able to vary the percentage of liquid oxygen in that part of the enriched liquid air adjacent to the magnet? Some of your numerous scientific readers may be able to throw some light on this question.—S. F. ELLWAND.

[96587.]—**Speed Indicator, &c.**—I am sorry to see my query (No. 96232, p. 452) has got among the "Unanswered," as there was a matter of business involved in it. Surely some of your North-country readers would be able to tell me at least the principle of the instrument by which the speed of the experimental train at the moment of applying the brakes was ascertained, as a large number of these trials were made on the North-Eastern Railway. Curiously enough, Mr. Michael Reynolds, in his interesting and exhaustive account of them, gives minute details of everything except this. The latter part of the query (re planimeter) could, I should have thought, be answered by any steam engineer. Perhaps "Regent's Park" can help me.—SCORPIO, Oystermouth.

[96588.]—**Wool Grease.**—A few years ago a patent was taken out for a rubber substitute stuff named as above. Can anyone give me the common names in trade terms of the above? Also, may I ask what is "wool pitch"? Is it a pitch, or a grease known as Yorkshire grease?—B.

[96589.]—**The Keyword Interest.**—Referring to the frequent use of this expression in the Dreyfus trial, will any of "ours" kindly explain what is meant by the keyword system of secret writing?—B. H.

[96590.]—**Motor-Cycles.**—Would "Monty" or "Writer of the Articles" appearing in "E. M." kindly oblige, if possible, by answering the following questions? I intend making a motor-bike somewhat similar to the one made by A. Garreau, so would be much obliged for any information given. (1) Would it be advantageous to alter the shape of ordinary diamond frame or size of wheels when building complete motor-bike? (2) What gauge of tube would be necessary to stand the vibration? (3) Would tandem tires do for wheels? (4) In regard to motor, would the one already being described in "E.M." do, or would it be better to reduce the scale to about ⅔, giving a cylinder 2in. bore? (5) Would this size of cylinder give enough power for travelling over moderately hilly country roads, the hills all being surmountable by a person on an ordinary bike (using a moderate ratio of gear for motor transmission)? (6) Is it necessary to have a flywheel for motor? Would not the momentum of bike, if the crank were balanced, cause the motor to act just as well? (7) What would be the best form of power transmission? My idea was to use the method seen on chainless bikes, only reversing the positions of gear-wheels. Would the advantages of ball-bearings for crankshaft motor compensate for extra trouble in making, &c.? Also, how would they stand the wear, &c.? (8) What is the amount of spirit and oil used on an average in one hours' run by a 1¾H.P. motor; also the cost, reckoning spirit at 9½d. per gallon, including waste from evaporation, &c.? Also oil used for lubricating, and current consumed from accumulator, the motor running at full power all the time? I have noticed several readers besides myself asking for information about motor-bicycles, they already possessing bikes, and would like to attach a motor, or, like myself, intend making a complete motor-bike. Any information given will, I am sure, be very much appreciated by all intending mobikeists and—F. R. D.

[96591.]—**Black Enamelling Small Metal Articles.**—Desire to black enamel small brass articles, similar to buttons and the like. Will some of "ours" kindly let me know modus operandi? Also what to use to enamel same.—W. J. P.

[96592.]—**Phonograph.**—I have read the articles and the correspondence on the grammaphone with great interest, but think the usual phonograph as seen at bazaars, entertainments, &c., a much superior instrument, and should like to know if an amateur mechanic possessing a good lathe and a slide-rest could construct such a machine with some amount of success. I have Gillett's book on the Phonograph, which appeared some years ago in the "E.M.," and think the instructions very clear, but before commencing should like to know if the instrument described has been actually made, and with what success. I see the shaft, which I should get out by an experienced firm, has a thread of 80 to the inch. Is it really so minute as this? As the articles appeared some years ago, it is possible that a better machine has supplanted the one described. Could anyone tell me if this is so? Another point which puzzles me is that the guide-rods are made of mandrel-drawn steel, which is said to be

only sold in 13in. lengths, and is supposed to be perfectly straight. What is mandrel-drawn steel? I should be glad to advertise my address to anyone who would be willing to enter into communication with me on the subject.—AMATEUR MECHANIC.

[96593.]—**New Storage Battery.**—Can any of your readers give any information about a new storage battery—Leightner (or Litner's) patent—which is said to be a great improvement on all others?—S.

[96594.]—**Ship's Tonnage.**—Will any kind reader explain the meaning of steamer's net and gross tonnage, tons burden, how it is taken, by measurement or weight? Also, please explain the horse-power, 500 nominal and 3,000 effective; which do they work at the Indian services of steamers?—ALGO.

[96595.]—**Foreign Books.**—Will any kind reader name any suitable books and dictionaries on engineering, published in Spanish and Portuguese?—ALGO.

[96596.]—**Waterproofing Textile Fabrics.**—Would any of our brother readers kindly inform me the composition of a solution for making muslin, calico, and cloth fireproof, and not spoil the colour of the material?—AJAX.

[96597.]—**Paint for Hot-Water Cistern.**—Will anyone inform me of a paint or other substance suitable for painting the inside of an iron cistern which contains boiling water, to prevent corrosion of the metal, and to stand well? Will be much obliged for information.—HAMISH.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** **Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, August 30, and unacknowledged elsewhere:—

WATTY.—A Reader.—William E. Tanton.—E. R. Dale—E. Wilson.—J. Sutcliffe.—Hear Both Sides.—Turner. H. Bevan Swift.—Britannia Co.

N. D. P., Oyzal.—Do not remember it; but as you say a firm was recommended to supply the tools, it was probably some other paper in which you saw the article.

ANXIOUS, Coventry.—Put a little oil round the stopper, warm the bottle, and tap the stopper sideways with a stick gently. It is usually sufficient to warm the bottle by holding it in the hand; but if that won't do, put it in the oven.

PROGRESSIVE.—Presumably you mean the cell described on p. 526, July 24, 1896. See the index of Vol. LXIII. It is much the same as a chromic-acid cell.

ED. MURRELL.—As you say, "the Scriptures are verified, and the wisdom of the world is foolishness," and the present system of astronomy is all wrong; but really, the weather has been too hot to think it all over calmly.

NON-SCIENTIFIC.—There are colleges and institutions where agriculture is taught, and there is no space at present to ventilate such schemes as you propose.

SUPERFLUOUS.—You can find all that is known about the removal of superfluous hair in the back volumes. Do not understand what can be meant by "on this really important subject there seems to be so little light thrown."

M. C.—Question too indefinite. See p. 191, last volume—the large telescope at the Paris Exhibition—and the indices generally under siderostat, coelostat, &c.

MOLD.—Please see Hints to Correspondents No. 4, above. The materials can be obtained at any of the shops keeping materials for dentists.

TOLO.—To what does the query refer—"melody coupler" for what?

JAMES D. HOYLAND.—Have no further information about the bifocal lens than that given on p. 5, Aug. 18.

D. M.—The appointments are made after competitive examination. Particulars can, no doubt, be had from the Civil Service Commission, Cannon-row, Westminster.

E. HITCHCOX.—The award has been made, and it is useless to quarrel with it on the point of a difference between "cart" and "van."

ISIS.—Bonney's "Electro-Plater's Handbook," published by Whittaker and Co., White Hart-street, Paternoster-square, E.C. (2) Ignition coils have been described many times.

P. M. STAUNTON.—Will look into the subject and the invention, and will probably publish a notice of same.

W. J. D.—Please see the back numbers. The question has been answered many times.

J. A. B.—Please see Hints to Correspondents No. 4.

L. E. S.—Several replies about cockroaches on p. 472, July 7.

A. W. P.—Apply to the Secretary of the Society. 2. They are appointed after examination. Apply to the Civil Service Commission, Cannon-row, Westminster.

FRANK.—Without particulars it is impossible to even offer an opinion as to the utility of the brake.

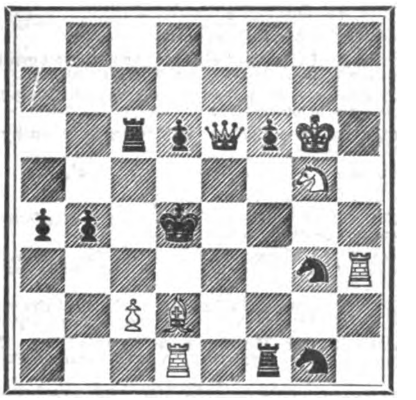
ENQUIRER, W. B.—You will find all that is known about liquid air in the back numbers.

CHESS.

All communications for this column to be addressed to THE CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1690.—A PRIZE PROBLEM.

Black. [9 pieces.



White. [7 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Sept.* 11.)

Solution of PROBLEM No. 1688.—By F. HEALEY.

Key-move, Q-K 2.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1688.—Correct solution has been received from Quisco, T. Clark, Richard Inwards, Whin Hurst Oracle, J. E. Gore, Rev. Dr. Quilter, F. B. (Oldham), Hampstead Heathen, (who adds, "Either this 'Hampstead Heathen' is a great fool, or this is the cleverest problem I have ever seen in the 'E.M.' It was hours before that key-move struck me. It looks so unlikely, and yet the moment you see it the whole thing is obvious. The key-move is wonderfully well hid."

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions.
7s. 0d. ..	6s. 6d. ..	6s. 0d. ..	5s. 6d. ..	5s. 0d. each.

Per Column.—

1	6	13	26	52 insertions.
£3 0s. ..	£2 15s. ..	£2 10s. ..	£2 5s. ..	£2 0s. each.

	1	6	13	26	52 insertions.
	£ s.	£ s.	£ s.	£ s.	£ s
Per Page....	8 8 ..	7 0 ..	6 0 ..	5 5 ..	5 0 each.
Half-page ..	4 10 ..	3 15 ..	3 10 ..	3 0 ..	2 10 ,,
Quarter-page	2 10 ..	2 5 ..	2 0 ..	1 15 ..	1 10 ,,

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "———," care of the ENGLISH MECHANIC Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC."
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

TERMS OF SUBSCRIPTION.

PABABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV, LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Iron Lathe, 4½in. centre, 3ft. 6in. bed. die chuck, heavy flywheel, all parts complete. Exchange for Harmonium or offer.—33, Amersham-road, New Cross.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, SEPTEMBER 8, 1899.

MOTOR CYCLES.—XVI.

THE petrol tank, Fig. 96, is made of No. 20 B.W.G. sheet brass, the body being bent to shape and the joint made hooked and well soldered. This joint should come on one of the flat sides, so as not to interfere with the fitting of the mountings around the filling hole, and for the cock and union for float supply-pipe. If any difficulty is anticipated in making the hook form of joint, any good tinsmith will undertake to make it at a small price, they usually having a machine for this work. The ends are to be hammered to shape from brass sheet of the same thickness as the body, and will require frequent annealing to prevent the metal from splitting. When shaped up and flanged they may be soldered to the body, in which the filling hole should have been previously cut. The collar on to which the cap covering the filling hole screws is seen in Fig. 97, and the cap itself in Fig. 98. They are both of cast gunmetal. The collar, Fig. 97, is best bored out and driven on a mandrel, when the outside can be easily turned and screwed 1in. diam. by, say, 16 threads per inch. The cap, Fig. 98, is to be screwed to match, and the outside nicely finished off and polished. The collar is secured to the petrol tank by four ⅛in. countersunk rivets, and soldered to make it spirit-tight. For the attachment of the petrol pipe and cock a gunmetal casting from the same pattern as Fig. 97 will be useful. It should be cast solid, and a good quality small cock and union be purchased, the casting being bored and screwed to suit the cock. When finished it may be riveted and soldered to the tank, with its centre 3¾in. to the left of the tank centre when looking from the back of the tricycle, so as to correspond with the position of the float chamber. If not exactly over each other, the copper pipe can be bent to suit.

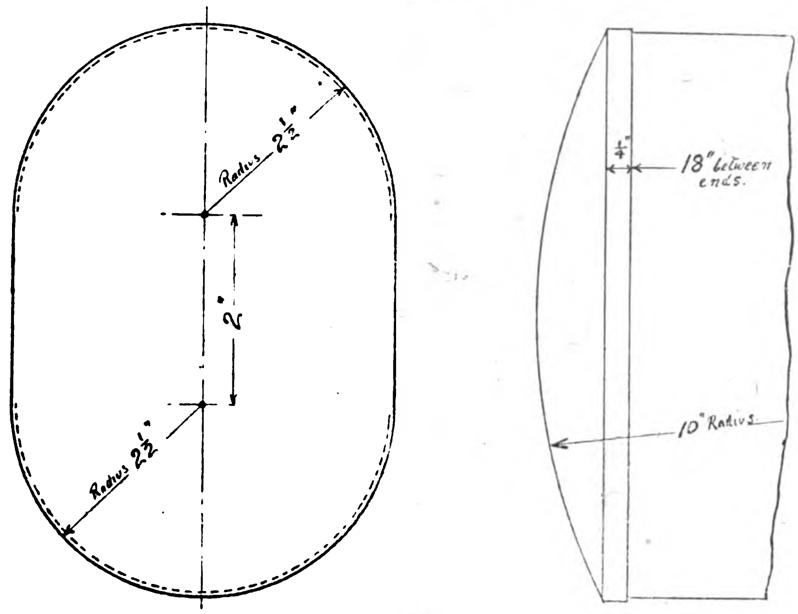

FIG. 96.

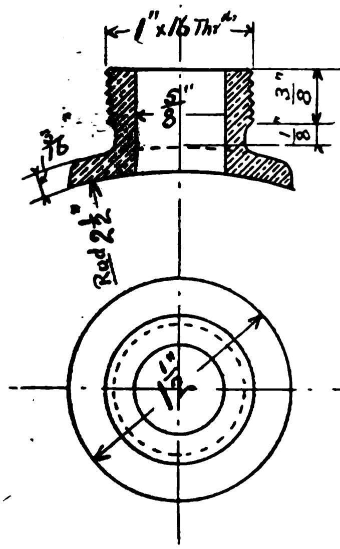

FIG. 97.

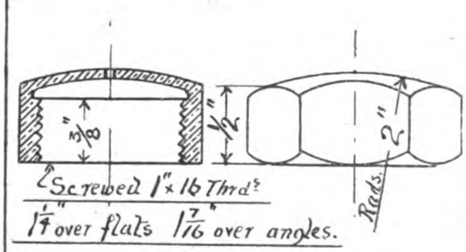

FIG. 98.

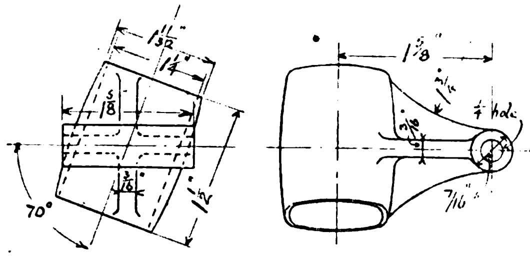

FIG. 99.

The bracket which supports the extension rod from the compression relief cock is shown in Fig. 99. It is to be cast in malleable iron, and brazed to the seat-column of tricycle in such a position that the ¼in. hole in the bracket is truly in line with the centre of the plug of the cock on cylinder head. A length of ¼in. steel rod is then taken, and one end coupled to the plug of cock by means of a short piece of iron or brass tubing slipped half over rod and half over the projecting end of plug, a 1/16in. pin being put through each end of the tubular coupling to make all secure. The other end of the rod should project far enough through the bracket, Fig. 99, to take the boss of the lever, Fig. 100, which is to be brazed on. On to the top tube the malleable cast-iron lug, Fig. 101, is to be brazed. Its position is best determined by putting the gear together temporarily. To do this we shall require the small lever, Fig. 102, in a finished condition. Place it in position in the fork of the lug, Fig. 101 (shown dotted), and pass a ¼in. bolt through fork and lever. Now move the lug along the top tube until the lever, Fig. 102, is vertically over the lever, Fig. 100, on the end of the compression-cock rod, and, having removed both bolt and lever, braze it securely in this position. The handle part of the lever, Fig. 102, is to be on the left of the rider, and, as seen dotted in Fig. 101, is in the position it will occupy when the cock is open. The lever, Fig. 100, is to be inclined upwards, also at 45°, when the cock is open, its small end being towards the centre of the machine. The upper and lower levers are coupled together by a ¼in. steel rod, forked at each end to take the smaller ends of the levers. I would suggest a couple of bicycle brake-rods welded together, or brazed with a long scarfed joint, being used for this part. They can be bought as stampings, and will save a lot of troublesome forging. On to the top tube, in any convenient position such as is given in Fig. 95, the bracket, Fig. 103, is to be brazed. This bracket carries the air and gas regulating levers, Fig. 104. It is of malleable cast iron, the quadrants being for a small pin (X, Fig. 104) on the back of the levers, to bear against, to prevent the levers

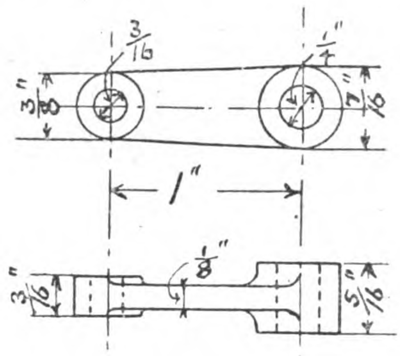

FIG. 100.

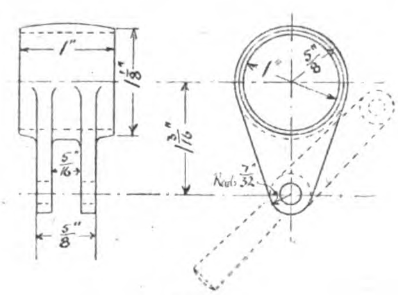

FIG. 101.

moving while running. On these quadrants the best positions for the levers will afterwards be marked. The levers themselves, Fig. 104, are to be of forged steel, a certain amount of spring being given to the thin part between the handle and the central boss. The pin X is riveted in, the edge which

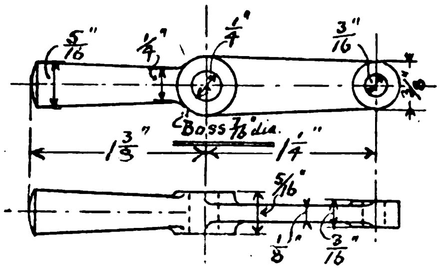

Fig. 102.

bears against the quadrant being wedge-shaped to drop into shallow recesses afterwards cut to receive it. The handles are turned from horn, ebony, or any other material which may be fancied, and secured to the lever by riveting over the end of the ⅛in. pin forged on the lever. Three of these levers will be required, one each for the air and gas handles of the mixture-cock on carburetter, and one for controlling the ignition gear. For this latter another bracket like Fig. 103 will be required, but with only one quadrant on the left. These three levers are coupled to the carburetter-cock and ignition gear-box by ¼in. rods,

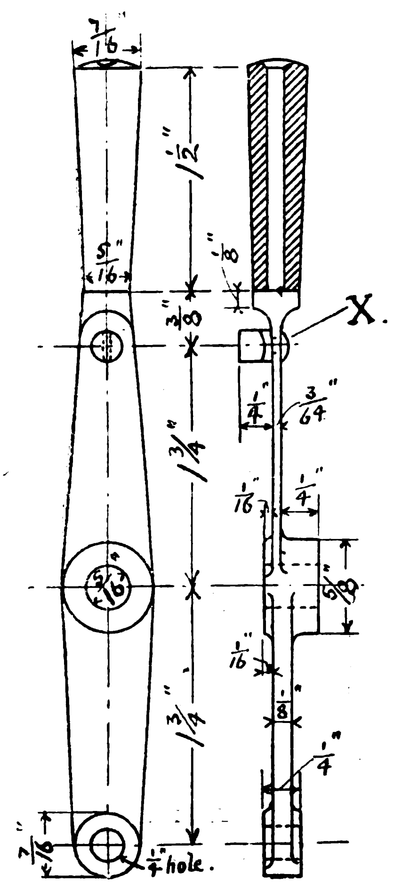

Fig. 104.

forked at each end, made in the same way as those just described for the compression relief gear. They are pivoted to their brackets on the top tube by 5/16in. turned bolts. Fig. 105 is the bell crank lever pivoted to the lower head lug, which changes the downward movement of the brake-rod into a direct pull on the rocking levers situated on the bridge tube over the band-brake. It is forged from mild steel and finished bright

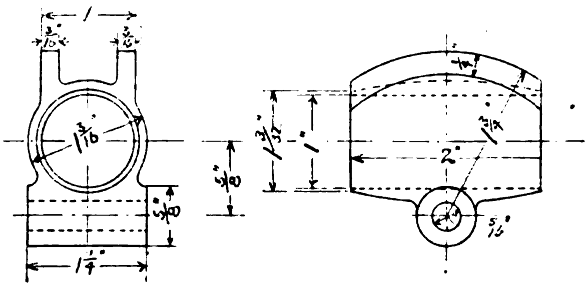

Fig. 103.

all over. At one end it has a boss 7/16in. diameter by 5/16in. through, to which a ¼in. rod, forked at each end as mentioned above, is attached, the other end of the rod being

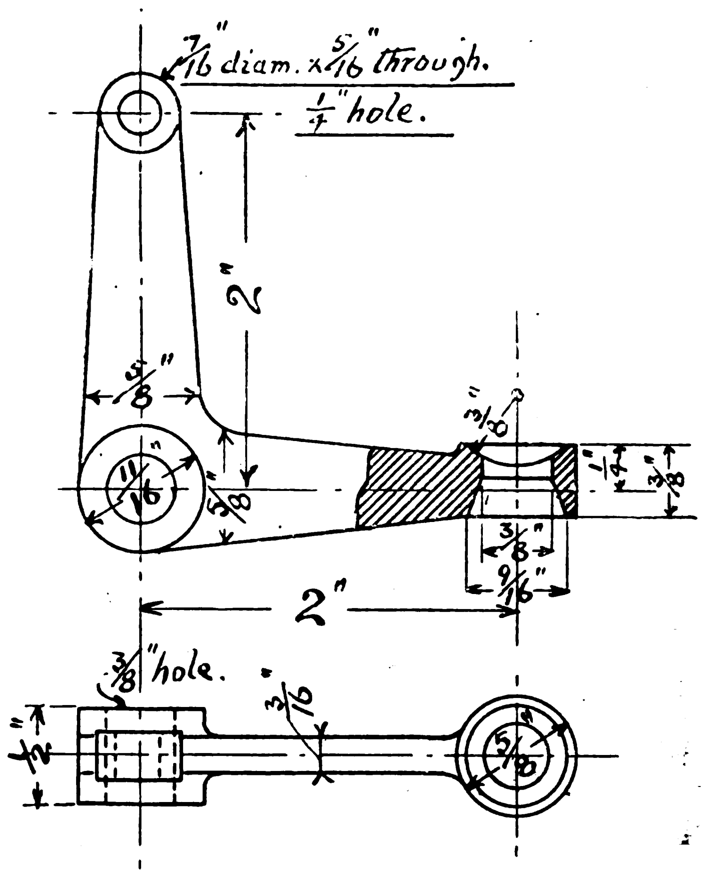

Fig. 105.

coupled to the vertical lever on the band-brake rocking shaft. The other arm of the bell-crank has a round boss, the upper side of which is cupped to a ⅜in. radius. A nut on the brake-rod is turned to the same radius to fit this cup; this nut being prevented from moving when adjusted by a lock-nut above it. By these means the movements of the handle-bar when steering will not strain the connection between the bell-crank and the brake-rod.

All these small levers, rods, and the bolts which connect them should be nickel-plated. The petrol tank and its fittings can also be plated if a very smart appearance be desired. In Fig. 106 I give a diagram of the electrical

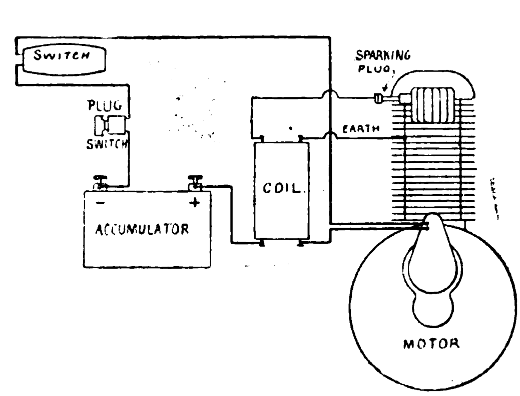

Fig. 106.

circuits. This is not drawn to scale, but merely serves to show the connections. The *thin* lines are the primary wires and the *thick* the secondary. Taking the primary first.

From the positive pole of the accumulator a wire leads direct to one terminal of the primary coil. From the other primary terminal of coil a wire leads to one of the contact springs of the ignition gear on the motor. From the other contact spring a wire is taken to one contact of the handle-bar switch, from the other contact of which the current goes through a plug switch to the negative pole of the battery. The secondary circuit is very simple: One terminal of the secondary of the coil is "earthed" on to the frame of the tricycle, the other terminal being joined to the insulated terminal of the sparking plug. Thus, when the plug and handle-bar switches are "on" and the motor is rotated, the circuit will be completed every second revolution through the two contact springs and the cam in the ignition gear-box, which will cause a spark to jump the gap between the points of the sparking plug, and fire the charge in the combustion space in the engine cylinder.

This article completes the description of the tricycle "built for one." Any small details I have omitted are such as can easily be bought or copied from ordinary pedal-driven tricycles. In my next I shall describe how to use the machine, and how to put right such breakdowns as are most likely to occur.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—III.

WHEN the pressure of the air is exerted on the mercury in a barometer, a certain amount of inertia has to be overcome before the column will rise, and hence the movements of a barometer are always a little behind the changes which take place in the air. Moreover, when the movements of the mercurial column are employed to produce an automatic record of the barometric changes by moving a float or by actuating a lever, for instance, the indications of the instrument are likely to be still more sluggish. The simplest mode of harnessing, as it were, the mercurial column is seen in the familiar wheel or dial barometer, where a float placed in the short leg of the siphon moves a pulley and spindle with a pointer attached. All such attempts, however, to make the barometer do work result in a slowness of movement which, despite great refinements of mechanical construction, is always very pronounced. Owing to this fact there is always a certain amount of suspicion attaching to the records of such instruments, and, although there are a very large number of self-recording barometers wherein the mercury, as it rises and falls, is made to work the recording apparatus, great care is required to keep them in a satisfactory condition.

To some people the temptation to try experiments with meteorological instruments is irresistible, and in those cases where certain types of barometers have got out of order, or are being put to no practical use, there is something to be said for making an attempt to transform them to something useful. The siphon barometer has always been a favourite with inventors and experimenters, since it is possible to insert a glass or ivory float in the short limb, and to this float, which rises and falls with the movements of the mercury, it is possible to make such attachments as shall be the means of securing a continuous record of the variations in atmospheric pressure. For this purpose it is desirable that the calibre of the barometer tube shall be large, and tubes of as large a diameter as 3in. have been used in constructing these self-recording instruments. To the float may be attached a delicate chain, or silk thread, which passes over a wheel, the float being counterpoised by a small weight. The wheel, as in the dial barometer, carries a hand or pointer, and on this there is a small pricker or point which is in close contact with a strip of paper revolved in the usual way by clockwork. The strip of paper which carries horizontal lines for the barometer scale and vertical lines for the hour spaces, may be made to serve for a day, a week, or even for a month. All that is now required is that a small hammer adjusted like the striking lever of a clock may be so arranged that at certain definite intervals it may strike the pointer, and so impress a mark on the paper which is, of course, moving slowly round on the cylinder. In other types of this instrument the wheel becomes a lever beam in which the two arms terminate in arched heads, one limb being twice the length of the other. This difference in the length of the arms is necessary because, as the mercury rises in the short limb of a siphon barometer, it falls an equal amount in the other, and the real height of the mercurial column is the difference between the readings shown by the two legs. A rise of half an inch in the short limb, therefore, really means a fall of one inch in atmospheric pressure. The cord from the float is accordingly attached to the short arm of the lever so that longer arm moves twice the extent, and the result is to record not merely the movements of the float, but those of the barometric column as a whole. In this form of barograph the pointer is also struck by a hammer, and the readings of the instrument recorded as often as desired.

Other successful attempts have been made to secure a continuous record of atmospheric pressure by converting the barometer into a pendulum, which is caused to swing as the mercury, in response to changes in the pressure of the air, flows from one tube to another. By this arrangement the barometer tube is fitted to an L-shaped glass pipe, which, in turn, is connected to a U-shaped tube, a small descending pipe serving to join the two together. The lower end of the U-shaped tube, as in the siphon barometer, is left open, and since the barometer swings on a horizontal axis placed above the centre of gravity, it moves to and fro as the mercury rises and falls. As the pressure increases the barometer swings to the right, and goes to the left as the mercury descends. The U-shaped part of the tube has a recording pen or pencil attached to it, so that the vibrations may be recorded in the usual way on a suitably ruled strip of paper. These self-recording barometers, which thus depend for their motive force upon the displacement of their centre of gravity, are by no means of complicated structure, and are very sensitive to atmospheric changes, and may be considered to be a very reliable type of barograph.

The siphon barometer may also be employed to secure a photographic record of atmospheric pressure, and, similarly to the barographs described above, the mechanism of some of these instruments is not unduly complicated. As before, the motive force is derived from a float inserted in the short limb of a siphon barometer, and, instead of being connected to a pulley and spindle, the float is attached to a lever. As the float rises or falls, the lever is raised or depressed, and at one end of it there is fixed a small circular disc with a tiny hole in it. Behind this disc a lamp or gas-jet may be placed, so that the light passes through the pin-hole on to a strip of sensitive photographic paper wrapped round a revolving cylinder. This paper has, therefore, imprinted upon it a curve or trace which, after it has been developed, clearly shows the variations which have occurred in the atmospheric pressure from hour to hour throughout the day. The details of this instrument similarly to those already described do not present any great difficulties in construction, and with moderate mechanical skill it should not be hard to make a barograph of this kind. Similarly, however, to other meteorological operations in which photography plays a part, the work of developing the records does not find favour with observers, and a large amount of enthusiasm is required to keep the instrument in continuous action.

As already intimated, the great drawback to all those self-recording instruments which depend on floats, pulleys, and levers is found in the fact that the mercurial column is restrained in its movements when it is made to put these attachments in motion. It is for this reason that barographs of this type are not employed at the first-class observatories in connection with the British Meteorological Office. The barographs at these stations, which, for financial reasons, are few in number, are, indeed, constructed on a photographic basis; but the mercury in the tube has no work to do in the way of moving floats or other mechanism. In these instruments, what is done is to photograph the space at the top of the tube, and, since this space decreases or increases as the mercury rises or falls, the result of photographing it is the same as if the movements of the column itself had been registered. The curve thus produced is not a thin line, as in the case where the record is obtained with a style or pencil; but it is a broad band which, of course, changes in width as the space at the top of the tube in enlarged or decreased. Several of these photographic barographs have been working continuously for more than a quarter of a century, and it need hardly be said that for researches into those difficult questions connected with the discovering of periodicities, such records are invaluable.

A self-recording barometer very much in vogue, and of which there are many different types, registers the movements of an aneroid, a lever attached to the upper part of the aneroid working a pen which imprints a record on a strip of paper wrapped round the usual revolving cylinder. So excellently are some of these barographs constructed that with ordinary attention they go for a long while without getting out of order. They are, moreover, so low in price as to be within the reach of everyone, and it is not surprising that these instruments are very popular with private meteorologists who do not wish to be bothered with complicated mechanism. But like so many other self-recording instruments, their weak point is often found in the pen and in the ink, which are responsible for producing a legible and continuous trace or curve, and it always pays to spend a little time in keeping these essential parts in good condition. Commonly the pen is something like a small bird's beak, and is adapted to hold a large charge of ink; while in other instances some form of stylographic pen has been taken into use. But no matter what kind of pen is employed it will require care in filling it, and in maintaining a free flow of ink. Moreover, seeing that all aneroids deteriorate sooner or later, frequent comparison with a verified barometer is advisable if an owner of one of these barographs desires to gain early information of any defect in its working. Given, however, reasonable care and attention, these aneroidographs are admisable for showing at a glance the hourly and daily variations in atmospheric pressure.

On looking at one of the curves obtained by any of these barographs, the first thing which strikes the eye is that there are a series of what may be called hills and valleys, and it is the rate at which the barometer rises to a peak or sinks to a depression that tells the most as to coming weather. It is very well known that a sudden fall in the barometer is a sure sign of coming bad weather; but it is not always realised that there may be a gradual drop to a very low level without anything very unpleasant happening. Conversely, a rising barometer is considered to be a prognostic for fine weather; but a sudden rise is often followed by disagreeable weather, and it is only when the barometer rises to a considerable height by slow degrees that a continuance of fine days is to be looked for. But as illustrating the difficulty experienced in discovering the kind of weather likely to follow any given movement of the barometer attention may be directed to the many different circumstances which may, for instance, cause the barometer to fall. Ordinarily a falling barometer is caused by some cyclonic form of distribution of atmospheric pressure, the barometer readings decreasing from the circumference of the system towards the centre, where the lowest readings are to be found. There is, therefore, in the first place, a fall in the barometer due to the arrival of the front area of one of these cyclonic disturbances in the neighbourhood of the observer, and the higher the velocity with which the vortex is moving forwards, the more rapid will be the fall. Again, the rate at which the pressure decreases from the circumference to the centre will depend upon the steepness of the atmospheric slopes or upon the barometric gradients, so that as the storm passes overhead the rate at which a barometer will fall is ruled by the shallowness or the depth of the vortex. Further, the slope of the gradients is continually changing, and this also has its effect on the movements of the barometer, while an additional effect is to be traced to the fact that the distance of an observer from the centre of the storm is also continually changing.

Even, therefore, in respect of a simple fall in the barometer, there are several points for consideration, and when it is remembered that even those who have the electric telegraph at their disposal to send them at frequent intervals the changes going on in different parts of the country, find it difficult to follow the alterations taking place in the rate of travel and in the gradients of a cyclone, it will be gathered that a solitary observer has a still more difficult task when he seeks to interpret the records obtained

rom a single barograph. If, however, he be content to deal in generalities, he can often arrive at satisfactory results; but at all times he must be prepared to find his calculations upset by those subsidiary storms which even expert meteorologists do not as yet thoroughly understand. The barograph curve, or barogram, as it is called, shows when a depression or cyclone is approaching, and what an isolated observer requires to be told is whether the storm is going to be of strong or weak intensity, and it has been suggested that an observation of the way in which the outline of the curve changes from hour to hour will help him to the desired information. A fall, for instance, of three-tenths of an inch in an hour would produce an abrupt descent in the curve, and its appearance as compared with the base line would be convex; and when this appearance was noticed it would be reasonable to expect that the storm would be violent and of an unpleasant character. On the other hand, when the fall proceeds at a slower rate the curve becomes concave, and, as a general statement, this appearance would be followed by a weak intensity in the coming depression. The lowest point of the kink in the curve, of course, represents the passing of the trough of the storm, and during the prevalence of bad weather it is useful to know when this dangerous area has passed. With a rising barometer curve, similar convexities and concavities are to be recognised, and in this case concavity is a bad sign, while convexity indicates improving conditions. A commencement may therefore be made in interpreting the records obtained from one's barograph by searching for these convexities and concavities.

MILLWRIGHT'S WORK.—VIII.

ENGINEERS now in middle life have witnessed a great revolution in the drives of shafts, as well as in the shafts themselves and their bearings. The early mills had wooden pulleys chiefly, some of which yet survive; then came cast iron, to be in turn now largely displaced by built-up pulleys comprised chiefly of wrought iron and steel. Finally, wooden pulleys have come in once more, completing the circle of changes. Between these, therefore, the choice still lies, and they will often all be seen running in one and the same shop. It is not possible to say in the abstract that one type is absolutely better than the rest. But under certain conditions, one will be better than any of the others, and the millwright must exercise judgment in making his selection.

For heavy drives, in which much vibration is set up, cast iron is more rigid than wrought iron; cast-iron pulleys are more readily made than wrought in small dimensions. But outside these, and for all the general transmission in a shop, wrought iron and steel are preferable, because they weigh less. Being lighter by from 30 to 50 per cent., they stress the shafts and bearings so much less, producing a most important economy when, as is often the case, a single length of shafting has to carry several large pulleys. But apart from this, the wrought-iron pulley is a construction more in harmony with true running than cast iron. A cast pulley is never quite truly in balance unless it is turned inside as well as outside, which is too expensive for ordinary service. Cast iron is not well adapted to withstand the tensile strains which are developed at high speeds, and so broken pulleys are familiar in everyone's experience. Nor is this the worst, for the internal stresses in pulley arms, boss, and rim are generally of a somewhat uncertain character. It is not a little curious that after cast pulleys have been used for three-quarters of a century, observation and experience have led to entirely opposite conclusions as to the shape of pulley arms in England and in the United States. With few exceptions, we use pulleys with curved arms, while they employ for the most part straight arms.

Wrought iron and steel on the other hand are materials eminently capable of withstanding tensile stresses, and sudden fracture would not occur in these. And as the rims are formed of a sheet of uniform thickness the expense of turning is saved, and the pulley is balanced just as made. The differences in these pulleys are only those due to methods of manufacture, which are rather numerous, and which it is hardly necessary to enumerate in much detail. Speaking generally, they comprise a central boss of cast iron, arms of steel or wrought-iron tubes, to which the rim is riveted.

There are other reasons, too, in which methods of manufacturing are concerned why wrought-iron pulleys are preferable in many cases to cast. The latter are stocked in even diameters, entailing then the services of a large number of

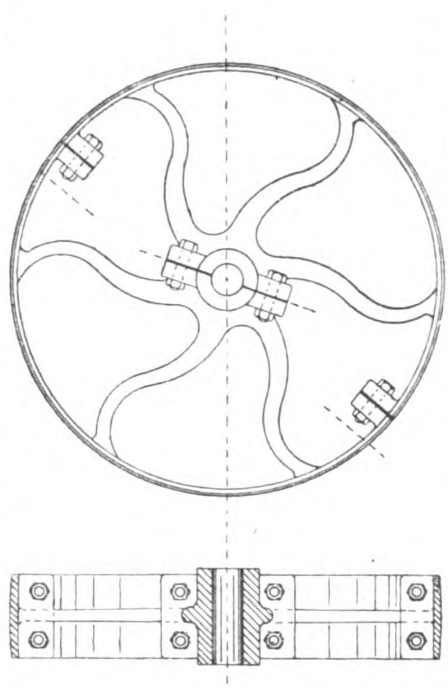

FIG. 47.

patterns. To obtain odd dimensions, which are sometimes wanted, involves extra cost and trouble in the foundry, as they are only produced by some amount of making-up or strickling in the mould. There is no such trouble

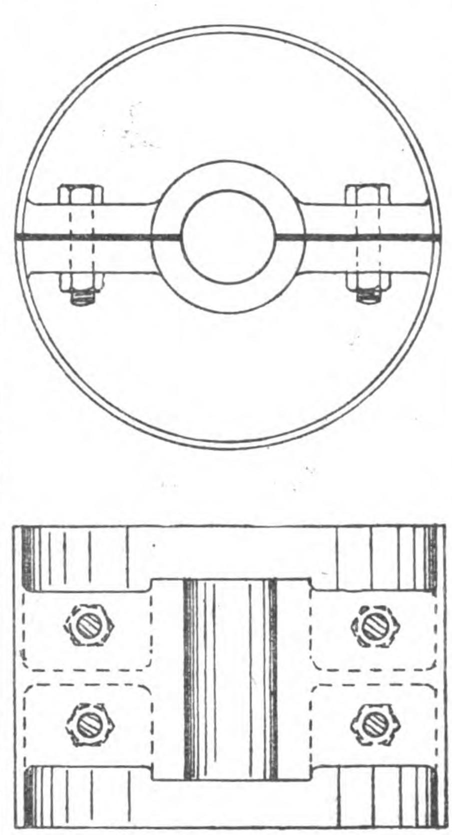

FIG. 48.

with wrought iron, because the rims can be rolled readily to any diameter required.

Another point is, that pulleys not in stock take longer to cast than wrought ones do to build up, and more especially so as diameters increase. Big deep pulleys require a deal of moulding, out of due proportion to the weight of the casting.

Altering the breadth of face of cast pulleys, it may be mentioned, involves no extra trouble beyond that of the difference in the depth of sand to be rammed. Standard rims of maximum depth and standard sets of pulley arms of given diameters are used, and all pulleys of that diameter are moulded therefrom, those of narrow face being stopped-off by ramming the rim up only to the particular depth required. The arms, of course, are detached from the pattern rim, fitting loosely within, so that they can be centred to suit any width of face required.

The pattern rim and arms are both made in

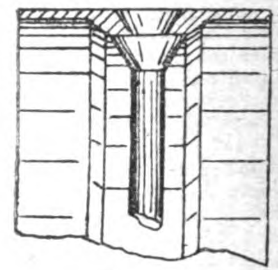

FIG. 49.

cast iron, the first being turned inside and out, with a little taper. The convexity of rim, when such is required, is imparted wholly by turning.

Another important difference in older and recent practice, is the practice of splitting so many more pulleys now than formerly. Splitting is rather a big job on a cast-iron pulley, and enhances the price to a greater degree than it does in wrought-iron pulleys. Splitting is therefore seldom resorted to in cast-iron pulleys, except when imperative. But in the laying out of shops now it is often the practice to employ divided pulleys of wrought iron and of wood throughout, or nearly so. The advantages are very great; for, though when a shop is laid out, there is often no anticipation of important changes having to be made subsequently in arrangements of machinery, yet such do arise with extensions of business and changed conditions of manufacture. Then the trouble begins, for it is no joke to have to shift solid pulleys along their shafts, while the removal of split ones is easily effected.

Another practical point is that splitting a pulley relieves it of tension, which is a great

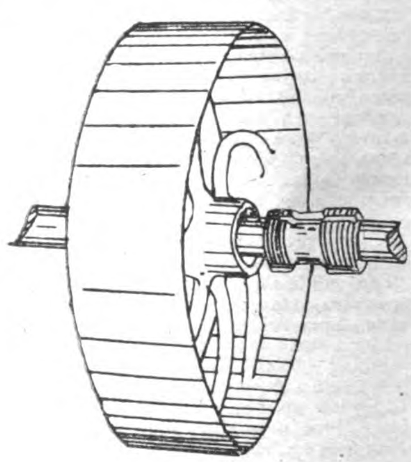

FIG. 50.

drawback to the use of cast-iron pulleys in general. Except by experienced judgment, you can never tell how near a pulley is to breaking.

Figs. 47 and 48 illustrate common types of cast-iron pulleys—large and small respectively. Both are divided; but without the splitting lugs they would remain as illustrations of solid pulleys. The lugs are set as shown in Fig. 47, because the curving of the arms prevents them being brought in line; with straight arms, the lugs would come in line. Fig. 48 represents usual practice in pulleys of a foot and less in diameter.

Pulleys of wrought iron and steel are variously made. Generally, the rim is in a single thickness; but the pulleys of Croft and Perkins have their rims constructed of a rolled section, which imparts a double thickness of metal to the central portions into which the arms are riveted, Fig. 49. This increases the rigidity of the rim and the

thickness through which the arms are countersunk, without adding much to the weight.

Although the screw-boss pulley system of Smith and Grace is well known, it would not do on that account to pass it by unnoticed, for everyone may not be acquainted with it. Briefly, it consists in this—that, instead of boring pulleys each to suit one size of shaft only, the pulley boss is screwed tapered, and the shaft is gripped by an elastic bush bored to suit the shaft, and screwed outside to enter the pulley boss. It was a bold innovation to abandon the time-honoured key and the driving fit, but results have justified it. It is very much on a par with the abandonment of the keyed coupling in favour of the gripping type. The screwed boss system not only avoids the disadvantages of keying—always an unmechanical arrangement when applied to work of this kind—but it also affords greater facilities for effecting rapid changes in the positions of pulleys, as well as for the transference of pulleys from one shaft to another of the same or of a different diameter.

In all sizes of shafts, varying from 1½in. to 6in. only four series of bushes are required; that is, the pulleys in that range are screwed to but four

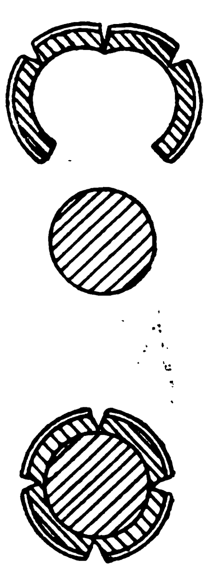

FIG. 51.

different sizes, and all the small variations in the diameters of shafts are made in the bushes. One series of bushes ranges from 1½in. to 2in., the next from 1¾in. to 3in., the next from 2¾in. to 4½in., the last from 4½in. to 6in.; so that one pulley may be used in any shaft from, say, 1½in. to 3in., by simply changing bushes.

The bushes are split in four and loosely-hinged, so that they can be opened to lay round the shaft; after being closed, the screwed boss of the pulley is run over them. Fig. 50 shows this, and Fig. 51 illustrates the bush in end view, opened in the upper figure, and closed round the shaft in the lower one. J. H.

CUTTER-BARS AND CHUCKING REAMERS.*

THE lathe is of very little use without small tools. First, as a matter of course, come the regular lathe tools; then for chucking and boring we need tools that will cut out stock faster than a common boring-tool. In a shop where the parts vary, and a good many changes are required, tools as shown here are very useful. There have been many improvements in these tools of late years, which make them more durable, and also enable them to do better work. They are also made in a way that allows of quicker setting and adjusting. Fig. 1 is a cutter-bar, as used a good many years ago, and many are in use still in the older shops. The weak points in this bar are, first, in the cutter *a*. The slot is so far down that it does not leave sufficient stock to hold the tit or guide from springing, and with very little strain it will break off. The weak place is shown at *a*, and also in the end view. When this tit breaks off, the bar is of no further use until repaired. In some of the earlier methods the slot in the bar was just the depth of the cutter, and a small set-screw was fitted to hold it, the point of the screw being let into the cutter. This method is not used very much

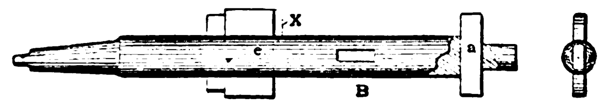

Fig. 1

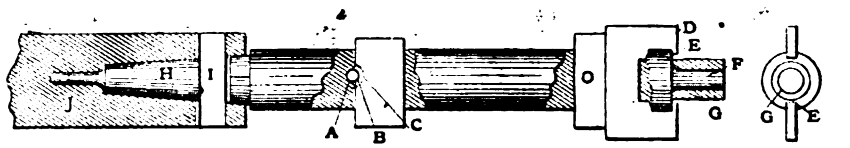

Fig. 2

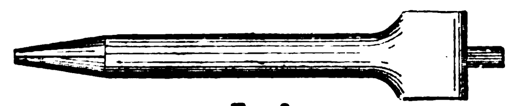

Fig. 3

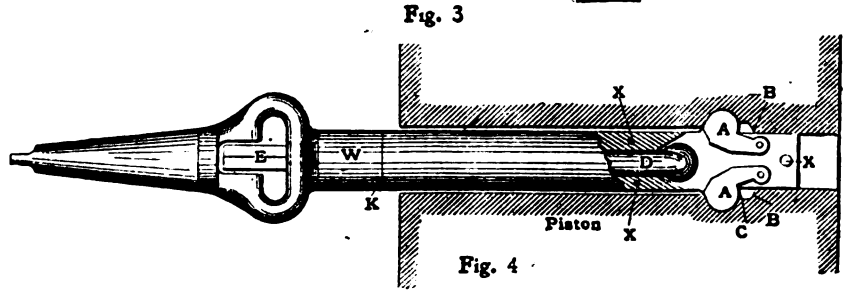

Fig. 4

at present. Another method was to cut the slot deeper, and fit a key, as shown at B and at C, Fig. 1. The objection in this case is that the cutter is not held in a central position. With a heavy and varying cut, it will move from one side to the other and loosen the key. A better way, and now a very common one, is to lip the cutter down on the bar, as shown at *x*, Fig. 1. The cutter may be put in a lathe and bored out to fit the round surface of the bar, or it may be cut out square, and a flat surface filed on the bar, so that the cutter will fit snug. The cutter should then be keyed into the bar and turned up. With this method it is not necessary to plane the cutters, as the steel in the bar is near enough in size to fit in. Where there are a number of cutters to be made, it is a good plan to cut them off, place the lot in a shaper or milling machine, and cut the recess for the bar in all of them at one setting.

In Fig. 2 we have a very strong and substantial bar. It may be used in a lathe or drill-press. By keying it into the lathe or drill-spindle, as shown, it will do very quick work in lathe chucking, or as a counterbore in a drill-press. There are two ways of fitting the cutter shown, both of which are good; but the one at the end is the better of the two, as it is lipped down over the bar, as shown at E. In addition to its being let down over the bar, it is fitted sideways into it. This supports the cutter, and allows of its being forced very hard into the work. It will be noticed that the tit is much stronger in this case than in Fig. 1, as the cutter slot does not come to the end. Another improvement is the sleeve *g*, fitted over the tit F to protect it from wear, and also to allow of changing the diameter of the tit for different work. This sleeve should be hardened and held from turning on the tit by a small pin fitted close up in the neck. In fitting up cutters of this kind care should be taken to fit the key O so that it will have a bearing all the way across, and not on one end, as it is apt to cant the cutter. At A, B, and C, Fig. 2, is shown another and very simple way of holding a cutter. It consists of a taper pin turned round and flattened on two sides. It has a bearing on the bar at *a* and on the cutter at B, while the bar is filed as shown at the dotted line C, for clearance. This allows the pin to hold the cutter hard against the bottom of the slot.

Fig. 3 is an old-style tit-drill or counterbore, gotten up for short, quick jobs. The trouble with it is in the danger of breaking off the tit, as that is hardened with the lips. It is not much used at present, as the shank for driving is of such a shape that it tends to force the spindle of the machine in which it is used up from the square taper. This racks the machine and loosens the parts. Still, there are some of them in use, and will be for years, in the jobbing shop. While some of our modern mechanics will say, "Throw it in the river," the country boy will say, "You give me that drill and our old drill-press, and I will finish up a job just as quick as you can do it in your newfangled, hyfernuten, what-you-call-'em machines. That drill helped my boss to earn dollars when he couldn't afford to buy improved tools, and it taught me to think and plan, and made me a better mechanic than I should have been if I had been raised on an automachine that takes in pig iron and turns out steam-engines."

Fig. 4 is a special tool designed to cut out stock over a check-valve in a deep piston, to allow the liquid to pass the valve. This space is shown at *a*, where the cutter is set out for service. The valve-seat is shown at B. This seat is formed by the cutting edge C of cutter A. These cutters A A are set out for cutting by forcing the rod D down hard between them. The end of the rod is spherical, and this is forced down by a screw thread, located at W, inside of the sleeve. At E we have a square for a wrench. The whole arrangement is used in a drill-press, keyed into the spindle, as in Fig. 2. The cutters swing on small pins, and will drop back in place when the ball is raised, which allows the tool to be taken out of the hole. This device was designed for a special job, and, of course, will not come in for regular work. But it stimulates a line of thought in some other direction, and may help the other fellow out. It is made up in sections, and riveted together at X X X. At K it is jointed together to allow of cutting the internal thread at W. Tools of this class are very expensive, and if the designer of the work on which they are used will look into the tool end of the job, he will save a good many dollars. Sometimes it is necessary to cut a part of a machine in two or more pieces, to avoid the use of such tools. But this is a good thing to do, when we consider the repairs later on. If special machines could be taken to the shop for repairs when out of order, the design would not cut so much of a figure. But the repair bill on a badly-designed machine has often lost the builder an order for a second one.

THE RELATIONS OF PHYSICS AND ASTRONOMY TO THE DEVELOPMENT OF THE MECHANIC ARTS.*

(*Concluded from p.* 59.)

VIII.—Education in Science and Training in Art are Mutually Helpful.

IF science both stimulates the arts and feeds the artisan with necessary physical data; if the laboratory of the investigator and the workshop of the artisan are thus intimately associated together, how is it with the young men themselves who are to become either artisans or scientists? How is it with the education of our youth? Fortunately, laboratory practice, or the teaching of physics by means of systematic personal experimentation in appropriate laboratories has been introduced into all of our best institutions of learning. It is now clearly recognised that the only satisfactory education is that which gives the student both a knowledge of the discoveries of others, and personal practice in the art of discovery. The study of nature is not

* By Prof. CLEVELAND ABBE, U.S. Weather Bureau, Washington, D.C. An Address delivered before the Franklin Institute.

conducted by haphazard methods, but is itself a highly-developed art. The courses in practical arts and the courses of scientific study should not be widely separated, but should be considered as being essential portions of one course of education. In an address delivered in 1883, at Johns Hopkins University, the Hon. S. T. Wallis said that no phrase illustrates the action and reaction of the practical man and the scientist upon each other better than that due to Mr. Huxley: While all true science begins with empiricism, it is true science only in so far as it strives to pass out of the empirical stage into the deduction of empirical from more general truths." The average citizen imagines that the learned man of research is set apart from everyday life. He needs to be reminded daily that the electric light, the incandescent Welsbach, the brilliant acetylene, the ordinary gaslight, are all evolutions which the practical world owes to the physical laboratory; that not only the electric motor, with its halo of mystery, but the ordinary steam-engine, which is but little less mysterious to the uninitiated, and the turbine-wheel, which everyone imagines he can admire intelligently, are wholly the creations of the practical scientists who have given of their knowledge freely to the world of mechanic arts. We must not attempt to separate investigation and education from invention and manufacture. We need to bring them closer and closer together than ever. I may quote from Dr. Wallis the case of a fireman or engineer of many years ago, in the days when the explosions of boilers were more frequent than now, and were an important object of investigation by the Franklin Institute. His boiler had exploded disastrously; he was called upon to give his testimony, and proceeded to state that "no one could know anything about these things except a man who had been brought up in the boiler-room, and that the particular explosion in this case was, undoubtedly, due to the gases in the boiler." When asked what gas, he replied with an air of triumph: "How can I tell? I was not inside the boiler." Fortunately, such ignorant men are not now allowed to have control of boilers and human lives. Safeguards and protective devices of all kinds have been attached to the boilers, and, indeed, all other kinds of machinery; but, after all, the essential element of protection lies in the training and intelligence of the men in charge. It will be a happy day when every university has attached to it a school of mechanical engineering, so that the practical world of action and work may profit all the more by the scientific wisdom and broad learning of university scholars. These crude remarks of mine will, perhaps, have already accentuated the importance of a thorough education along mechanical and physical lines, if one intends to devote his life to the improvement of the mechanic arts. As I have said before, one may, by a fortunate and accidental collocation of ideas, be put in the way of making an important invention or improvement; but the chances are all against this unless one has been pursuing such a course of education and training as will have fitted him to recognise the importance of the ideas when they suddenly occur to him, and to embody them appropriately in the metal and material of which his machine is to be made. Many a bright thought occurs to those of us who have not trained skill in the art of composition, and, therefore, we fail to become poets and musicians; many a man witnesses daily some little operation going on about him, but fails to make it the basis of a new process in the mechanical arts, because his thoughts do not run that way. In general, the most important improvement in machinery originate with those whose daily work familiarises them with the special subject and its needs. It is fortunate that the tendency of the present generation is very decidedly towards the thorough education in physics of those who inherit a liking for machinery, in the belief that thereby they will certainly be better prepared to contribute towards the advance of our arts, and to compete with those who, throughout the world, are revolutionising the progress of civilisation. America holds its own with England and Europe in this respect. The following prominent training schools may be mentioned:—The Sheffield School of Engineering, at New Haven, founded in 1847, but in 1860 changed to the Sheffield Scientific School of Yale University; the Lawrence Scientific School, with its recent addition of mechanical engineering, founded in 1847, at Cambridge, Mass.; the Massachusetts Institute of Technology, founded in 1861; the Worcester Polytechnic, founded in 1865, at Worcester, Mass; the Packer School of Engineering, Lehigh University, Bethlehem, Pa., founded in 1866; the Stevens Institute, at Hoboken, founded in 1868, opened in 1871; the Sibley College of Mechanical Engineering and the Mechanic Arts, at Cornell University, Ithaca, N.Y., founded in 1870; the Case School of Applied Science, at Cleveland, O., founded in 1877; the Rose Polytechnic, at Terre Haute, Ind., opened in 1883. The graduates of these institutions are now everywhere coming to the front in our workshops, in the Patent Office, in the manufactories, and even in our politics, for, of course, the practical mechanic and engineer must be represented in the State and Federal legislatures. I notice that in Germany both merchants and manufacturers have lately united in stimulating the education of mechanics and artisans as an important step towards improving the quality of their goods and the condition of German trade. The manual training-schools, the working men's trade-unions, and other interested parties in the city of Hanover, have resolved to establish advanced lecture courses, in which artisans and apprentices in all trades shall have an opportunity to complete their education in mechanics. Only those will be admitted to the classes whose theoretical and practical knowledge is such as to give promise of success. Great care will be taken to teach young men how to obtain the most practical advantages from the knowledge imparted in the classes. A permanent exhibition of all power-machines and tools will be established. The needs and opportunities of a great technical college were forcibly set forth in 1893, in an article by Dr. R. H. Thurston, Director of the Sibley College at Cornell. After enumerating the large sums of money devoted to the support of educational institutions, he called attention to the fact that technical education in the mechanic arts, strictly so-called, had not—and we may still say *has* not—been sufficiently provided for. The present demand for trained electricians but emphasises the great need of training in every department of the mechanic arts. The provision for culture in literature, history, pure science, and the fine arts is far better; but that for technical instruction, manual training, and the art of doing as well as thinking, still calls for attention. Laboratory or engineering research is especially to be desired. Every piece of machinery that we are using to-day is in itself a field for investigation as to whether it is doing its work with the greatest efficiency and in the best manner possible; but such investigations demand a previous knowledge of the laws of mechanics and familiarity with mathematical methods such as the technical schools alone can give. The passage of a nation from barbarism to modern civilisation occupies a long time, and is always attended with a great increase in density of population, and a great rivalry between individuals competing for success. The interaction between all classes of the community grows more intense; those who are on top struggle to keep their vantage by calling to their aid all the resources of power and intelligence. Experience has demonstrated that in this contest intelligence wins, and that knowledge is power. There can, therefore, be no doubt of the wisdom and statesmanship of the community that improves every possible opportunity to develop the natural resources of its territory and the intelligence of its own citizens. Both in Europe and in America universities and surveys, arts and manufactures, morality and science, health and prosperity go hand in hand. Victory flies to those who are best prepared; peace rests with those who nurture the arts of peace. President Eliot has nobly said: "It is the regular pursuits and habits of a nation in time of peace that prepare it for success in war, and not the virtues bred in war, that enable it to endure peace." From this point of view—the highest that any philosopher has yet attained—we see at a glance the wisdom of those citizens who have encouraged the development of both material and intellectual resources. I join the material and the intellectual together, for neither is of use without the other. If it is the mind that studies nature, it is also the mind that conquers nature. The intellect is developed, strengthened, and quickened in this struggle with nature. A university includes every possible variety of education, theoretical and practical, mechanics and physics, the laboratory and the workshop. It stores up knowledge but only to diffuse it again in perennial streams.

Remarks of Prof. A. S. Mackenzie, Bryn Mawr College, "On the Claims of Abstract Science to a Place in the Franklin Institute.

Prof. Mackenzie:—Prof. Abbe has given us to-night a beautiful example of the value of theory when turned to practice; we all know of his researches on clouds and the clearness of the earth's atmosphere, but to-night he has descended from the clouds and shown his power to provide with a clear atmosphere the subject of the relation of pure science to the mechanic arts. I have listened to his remarks and those of Prof. Mendenhall with very great pleasure, but with a good deal of trepidation, for I fear that what I may have to say will but traverse the ground they have already so fully covered. Perhaps, however, I may be pardoned some repetition, for I believe that too much stress cannot be laid on the importance of the subject upon which Prof. Abbe has chosen to address us, and that progress in the future is to be made only by the theorists and the practical men keeping in the closest touch with one another's aims and needs. It seems to me that the event in the history of the Franklin Institute which we are assisting at to-night is a notable one in its progress, and one which shows the high ideals of the Society, and the broad aims of those to whom its management and direction are intrusted. We learn from the full title of the Institute that its aim is *the promotion of the Mechanic Arts*, and we read of its sections devoted to Mechanical, Electrical, Chemical, Mining, and Metallurgical Engineering as a matter of course. At first thought it might cause surprise that it had a section devoted to theoretical chemistry, and that it was proposing to add a Physical and Astronomical Section; it is, however, but living up to the many-sided character of the man whose name is so intimately connected with it, and whose investigations in the realm of abstract science are an integral part of our studies of to-day; and I think that not until now can the Franklin Institute be said to have reached the standard set by its founders, or to have been quite rounded out in its various functions. The line of progress and development of the society has been a natural one in this new and rapidly-growing country, where the production and improvement of appliances for the rapid development of the country's enormous resources have called to their aid the best thought and energies of its people. As a consequence, the technical side of science has been advanced more rapidly than its theoretical side; it is true we have had a Franklin and a Henry, but the production of such men has been spasmodic, and until quite recently the study of physical science was but nominally existent in this country, whereas now great strides forward are being made, and the names of Rowland, Newcomb, Gibbs, Michelson, &c., are known in every corner of the scientific world. It is more than a coincidence, I think, that to-day the Franklin Institute is forming a section devoted to Physics and Astronomy, and that the physicists of the country meet at New York to-morrow to found an American Physical Society; it proves that at last there is an awakening to the necessity of the study of science for itself, and to the belief that we are fit for better things than to be a nation of shopkeepers and inventors only. To the problems of engineering and technical science in its widest sense the Franklin Institute has in the past devoted most of its energies, and with great and growing distinction; the inventor or thinker to whom a John Scott or other medal of the Institute has been awarded has a recognised standing the world over, and the *Journal* of the Institute is consulted regularly by all engineers who wish to keep abreast of the progress in their special fields, and to follow the newer and more important processes and developments of their chosen work. But surely it is not necessary to add that, insomuch as it has not had among its sections one devoted to the study of physical science for itself, without thought of material gain or useful adaptation, it has lacked that one very necessary part of an advanced organisation devoted to mechanical science. I consider it a great privilege to be present at this auspicious opening of the Physical and Astronomical Section. The able address of Professor Abbe, whose reputation, already so well known, will not suffer from the interesting lecture we have just listened to, has emphasised the absolute necessity of a close communion between the men who are willing to be the devotees of pure science and those whose ideals are in a direction equally valuable, and the results of whose labours are felt directly by each one of us at our every turn. It is upon this necessary working together of these two groups of men that I think we should at this meeting lay stress. A science must exist before applications of it can be made, and hence the two divisions of the great work fall into the hands of two different sets of workers; and the nature of the work and the composition of mind required are quite different in the two cases. Not to the pure scientist belongs all the credit for the making of a science; the mechanic or engineer can, by constant thought and application, so get at the very heart of things that he becomes a co-worker of the theorist and advances our knowledge of the inner workings of nature; for a mathematical knowledge is not essential: it is a help, and a valuable one, and the man armed with this weapon for attacking a problem is at an advantage, provided he does not become lost in his symbols; and it must not be forgotten that Faraday wrought out his great work in the field of electricity without mathematical equipment of the higher variety. It is, however, to the theorist, not to the technical man, that we must look for the advancement of science; but this advance can never be so rapid as it should be unless both theoretical and technical men recognise their mutual dependence. Du Bois Reymond has somewhere remarked that there is no abstruse investigation into nature that does not at some time have its practical application, and, this being so, how essential it is that this investigation should proceed on a clear knowledge of the work done and being done by practical men. Perhaps no better illustration of the value to the theorist of a knowledge of the technical requirements of his subject can be found than in the development of the study of thermodynamics; it was the work of Watt and his successors that led to the brilliant achievements of Carnot, Kelvin, Clausius, Maxwell, Hirn, and others. Our whole knowledge of the laws of energy is almost a consequence of the researches called into being by the demands of engineers to know the principles underlying the working of the heat-engine. The theorist thus receives a constant guidance and check as well as incentive, and is forced to give a reality and definiteness to his

speculations which might otherwise remain in the clouds, and whose full significance would be known not even to himself. But to the technical man the assistance of the theorist is of much greater value. In addition to the direct aid afforded to the engineer by the new principles and discoveries of the thinker must be mentioned the fact that the theory not only guides the engineer in the direction of possible development and improvement, but that it acts as a beacon to warn him from the many directions in which his genius and labour would be barren of results, because he aims at the impossible. There never was a time when, more than now, the technical man must work hand in hand with the pure scientist. It requires the finest theoretical knowledge to devise a telegraph by the aid of which eight or more messages can be sent along a single wire in each direction at the same time, and yet we ordinarily consider telegraphy a purely technical subject. The engineer who would keep up with the pace which science is making must consider himself always in the schools; he must be trying to keep step with the changes in the theory, and with the growth of knowledge as proclaimed from the studies and the laboratories; he must, if he would win distinction, have the training which fits him to seize the idea behind the theorist's symbols and forms, and strikingly apply it to the everyday problems in which his interests and labours lie. The brain of the genius who can fasten upon the practical consequences of an idea brought forth by the mere thinker is one of the very highest order, and he deserves the merit he receives, and the world is quick to reward him in its substantial way, although the world is little able to discriminate, and is willing to believe the scribbler of any magazine article who prophesies plausibly a sudden demolition of the laws of nature which the labours of the greatest thinkers have placed on the most enduring bases. Just now we can see an example of such a thing with regard to the law of the conservation of energy; we are threatened with most improper doings by liquid air, and we have not yet forgotten the Keely motor. It is to the credit of the scientist that he is willing to give his life to the prosecution of learning for its own sake, and that, too, when an understanding and appreciation of his labours must be given to few. How common it is to hear that man who has made some application of value (measured in money or utility) lauded above the originator of the idea. One hears of this or that inventor of the electric lamp or dynamo, but not of Faraday, who made an electric arc fifty years earlier, and produced the electric current by induction and foreshadowed all its applications. One hears of a Hertz or a Marconi, with their electric waves and wireless telegraphy, but how seldom of a Clerk-Maxwell, whose seething brain put forth the thoughts of which these things are but adaptations. How often is Lord Kelvin's name connected with the problem of submarine cabling? One is almost tempted to say that the person of so-called average intelligence gives in his heart greater credit to the inventor of "see that hump?" than to the discoverer of the law of gravitation. Surely equal credit must be given to the originator of an idea with him who applies that idea to the purposes of mankind, and it must come home to us how necessary is the existence of a close bond between these sets of workers, so that each aids the other and to each is given the credit which is his due. Now I believe that not only will the founding of a physical and astronomical section bring about good results of this kind to the Franklin Institute; but I consider that it is only a beginning in the direction in which such an institution should be expanded. It should have its staff of professors, whose only duty it should be to pursue original investigation, and the results of whose work should be made known to the world through the society. Of course such things cost money, and being a practical people we hesitate to give our money to what we please to call unpractical purposes. I hope, however, that we have come to the conclusion that a full return for the money so spent is bound to come back to us in overflowing measure, though in indirect and unseen ways. It seems that our benefactors who give of their wealth to advance education are unwilling to pay for pure science; they willingly give their money to found and endow libraries, they give freely to art collections and to museums; but what cases can we recall of the founding of a laboratory for research only, a place where a Rowland could be put and told to go ahead regardless of expense and enrich the world's treasure-house of thought? The German Government has such an institution, and yet I would be sorry to see ours try to imitate it; for it would be difficult every four years to find a man of the right political complexion to take a well-earned turn at the "job." At the Reichsanstalt, to which I refer, and with which Helmholtz was connected in his later years, is a vast equipment, with its experts, to be counted not by units, but by hundreds, who devote their time not only to standardising apparatus, but also to the devising of the best and simplest forms of instruments and to the production of new ones; and in addition to all this is Prof. Kohlrausch, with a staff of fifteen or twenty assistants, whose only aim is original research in the field of physics. All the products of these men's brains and the results of their labours are given freely to the world. I know of nothing similar in this country in the domain of physics; Harvard College has one of its departments, the astronomical observatory, devoted entirely to research. Prof. Pickering and his associates give no lectures and no instruction in the observatory; they are expected simply to use their best efforts to promote our knowledge of astronomical science, and to this end are provided with a staff of forty assistants and a fully-equipped observatory and library. What better thing could be done by one of our moneyed men, eager to utilise his great wealth for the good of mankind, than to found, in connection with this and similar institutions, a professorship in physics, assuring to one qualified to fill it a liberal stipend (for even a Newton must eat) and all the appliances and assistants his genius can employ? Perhaps this has carried us too far into the future, and whether we shall ever come to this I do not know; but at any rate, I believe that the Franklin Institute has made a move to-night which will redound to its credit and usefulness, and I have taken great pleasure in being present at its inception. [Abstract of remarks of Dr. T. C. Mendenhall, President Worcester Polytechnic Institute, Worcester, Mass.] Dr. Mendenhall spoke substantially as follows:—"The excellent and carefully prepared address of Prof. Abbe leaves little to be said by those who follow him. It is a real pleasure, however, to be able to congratulate the Franklin Institute on the realisation of a plan which is a recognition, tardy though it may be, of the intimate relations between the mechanic arts and physical science, or, as some of us would be inclined to say, the dependence of the former upon the latter. When I read the subject for discussion I wondered how it could be a subject of discussion at all, for I am sure everybody knows and admits that progress in the mechanic arts rests upon and is measured by progress in the physical sciences. But it is no ordinary event in the history of either that the Franklin Institute, which may be justly considered the foremost organisation in the country, whose primary object is and always has been the higher development of the mechanic arts and the encouragement of American invention, has organised a special section for the better development of its interest in the physical sciences. When one reflects upon the splendid work of the Institute in its chosen field, the outlook for the future of this new section of physics and astronomy is most promising, and we are all confident that much important work will here be done. It is impossible to speak in this hall without constantly-recurring thoughts of the pioneers of American science. It is entirely natural that the present should appear to be the golden age, and among the historians of science in this country it is too common to pass over the seventeenth and eighteenth centuries as relatively unimportant. As a matter of fact, some of the most brilliant of America's contributions to science were made before the beginning of the nineteenth century, and, counted in proportion to the population, the number of eminent scientific men in those days was fully as great as now, and along some important lines their share of the world's work was greater. Perhaps the first contribution from America to the proceedings of a scientific society was the first communication of Gov. John Winthrop, of Connecticut, to the Royal Society of London, of which he was one of the earliest members. Another Winthrop, of the same stock, Prof. John Winthrop, of Harvard College, was also a frequent contributor, and doubtless did more to kindle and keep alive the fires of colonial enthusiasm for physical science during the eighteenth century than anyone else. But the one great figure of that period was one whose name and deeds are inseparably related to this city, and in whose memory this institution was founded. The world has produced few, if any, more brilliant men than Benjamin Franklin. It is with only one phase of his intellectual activity that we are interested to-night, and in that alone, as a physicist or natural philosopher, no one will deny that he must be reckoned among the very foremost. There is one quality of his scientific work to which I want to invite especial attention; it is the almost ever-present practical end towards which nearly every investigation was directed. On account of the great lustre of his researches in electricity, it is often forgotten that he enriched nearly every department of physical science, and although he evidently did not lack capacity for that keen enjoyment of discovery which depends upon discovery alone, and is indifferent to practical results, it is everywhere evident that with him the possibility of turning a scientific experiment or principle to good account as a means of bettering the condition of his fellows was paramount. There is a certain class of scientific men, not large and not increasing, we are glad to note, among whom it is the fashion to speak with what they believe to be a "fine contempt" of applied science, and who, having never succeeded in discovering anything of any particular value or use, pride themselves on pursuing science for the sake of science. And we have all heard of the mathematician who thanked God that he had at last discovered a formula of which it would be utterly impossible ever to make any practical use. But this doctrine has not been held by those most entitled to distinction in the annals of Science, and Franklin was a notable example of those who believe that the noblest ambition by which a man of science may be stirred is the ambition to discover laws which may be utilised in the amelioration of the almost necessarily harsh conditions by which mankind is surrounded. It is difficult to address a body of scientific men in this place without thinking of another great name —that of one who stood almost at the beginning of that long and unbroken line of astronomers for which our country is justly famous. And in thinking of Rittenhouse in Philadelphia one is likely to turn from the contemplation of his splendid career as an astronomer to that incident, so characteristic of the men of his time, in which the man of science became, at the behest of the Committee of Safety, the clockmaker again, designing and casting clock-weights in iron which were to be exchanged with the inhabitants of the City of Brotherly Love for leaden weights, to be moulded into bullets, which contributed to the founding of a new nation. During the life of that nation the most marvellous changes have been wrought in the material condition of man and his relations to the planet which he inhabits. We have ourselves witnessed so many of these changes that detailed reference to them is unnecessary, but we may profitably inquire concerning the underlying cause of such a prodigious revolution. To my mind it is found and found only in the discoveries in physical science, and in their application to the control and direction of the forces of nature. Man lives in this world only by the continued transformations of energy, and his comfort and happiness depend largely on the amount of energy he is able to transform. It is not long since his only supply was that furnished by the muscles of his own body, but during the 19th century he has been able, thanks to physical science, to draw upon almost inexhaustible sources from without, and this is why he has progressed by leaps and bounds that have exceeded the most extravagant imaginings of our ancestors. This progress cannot be attributed to war, for war has existed since the dawn of history, and it has failed to lift man above the slavery of unintelligent toil. Nor is it due to religion, nor literature, philosophy, or art, for all have flourished for ages without materially altering the relation of man to his environment. Science, with its unerring processes of observation, experiment, and precise measurement, has inaugurated the peaceful revolution in social relations and material conditions which the nineteenth century now passes on, still incomplete, to the twentieth. The pen has conquered the sword, but the yard-stick is potentially the master of both.

AMID THE ICE PACKS IN SOUTHERN SEAS.

NEWS was received some time ago that Mr. C. E. Borchgrevink and his brave companions had effected a landing at Cape Adair, in Victoria Land, within 200 miles of the South Magnetic Pole. As this is the first time in the world's history that a fully-equipped expedition has accomplished this feat, considerable interest attaches to it, and an article by Sir George Newnes in the September *Strand*, giving details, is sure to attract a good deal of attention. It has been prepared from the log of the *Southern Cross*, and is illustrated with many photographs taken during the expedition.

The Great Ice Pack.

Mr. Borchgrevink, it may be stated, has as his chief officers on board the *Southern Cross*, Captain Jensen, Sub-Lieutenant Colbeck, R.N.R., Mr. Hugh Evans, and Mr. Bernacchi, and they command a fine, stalwart crew. The voyage from London to Hobart Town was uneventful, but the reception that the crew met on arrival there was of the most enthusiastic description. The Governor presided at a banquet in their honour, and they were entertained at parties, conversaziones, and fêtes innumerable. The vessel left Hobart Town for Cape Adair on December 19 last, and before the old year had died out—on Friday, the 30th—she sighted the great ice-pack. "The greatest enthusiasm," Sir G. Newnes writes, "prevailed on board, for the sight to those who looked upon it for the first time was one to fill the spectator with wonder and admiration. Some of the floes were several miles in diameter and from 4ft. to 8ft. thick. The channels between them were very narrow, and at times closed up completely. The danger to the ship was great; but the *Southern Cross* proved equal to her task, and came triumphantly out of ice pressures which would have crushed a less solid vessel like an eggshell."

But there were some very anxious days. On January 22 and 23, for instance, "the ship was fairly buried in the ice; the great blocks rose to the level of the bowsprit, and the pressure of the floes was so

stupendous as to lift the vessel bodily 4ft. out of the water!"

Off the Balleny Islands.

At this time the expedition was off the coast of Balleny Islands. "No more appalling scene of desolation can be imagined than those sinister and ice-bound shores. At evening, however, gorgeous sunsets, which surpass description, glowing on iridescent floe and ice-peak, lend them a wild magnificence of beauty which compensates for all. Nor were the adventurers without resources. Very valuable scientific work was done, especially in the zoological department. No fewer than a hundred and seventy-five birds' skins were prepared. Many seals, including one of an entirely new species, were procured, as well as penguins and beautiful white petrels. More than a hundred species of various fauna were collected. Meteorological and magnetical observations were made, deep-sea temperatures were taken, and a number of most interesting photographs secured."

For forty-three days the vessel remained in the ice pack; but finally open water was reached, and an eastward course steered. The pack was then re-entered at another point, likely to afford an easier transit, and after a few hours the gallant explorers safely emerged in clear water to the south.

At Cape Adair.

Cape Adair was sighted on February 16. A terrific gale was blowing, and the vessel had to lay-to. Next day, however, the gale subsided, the *Southern Cross* steamed into Robertson Bay, and there an anchor was let fall for the first time in history:—"In half an hour the staff were all on shore. On the beach were penguins, gulls, stone-petrels, giant-petrels, and many huge seals of an unknown species. Two of the adventurers, Mr. Evans and Mr. Bernacchi, started off to climb to the summit of the cape. The ascent, over 1,000ft., proved terrible, and they did not reach the top till midnight. But they must have felt full compensation in the thought that they were first to set foot upon the summit of Victoria Land." The next few days were employed in landing stores and erecting huts. This was a task of no ordinary difficulty, but was eventually successfully accomplished.

A Terrible Experience on Shore.

But now a new disaster was before the intrepid explorers. On February 23 a great blizzard came on, and the experience of the men seem to have been a terrible one:—"The wind rose suddenly, and blew thousands of tons of snow upon the little camp. The gale blew with cyclonic force, and it was piercing cold—18° below zero! Four members of the staff—the doctor, Fougner, Colbeck, and Bernacchi—were on shore and could not reach the ship. The only shelter was the tent, which they were obliged to bury with stones and to lash with ropes, to prevent it blowing away. All that terrible night they were toiling in the blizzard to save the cargo from being washed away. Mr. Bernacchi got frostbitten in the ears, which turned quite black, and were only saved with difficulty. The hair of the party froze into solid lumps, and the ice upon their beards took hours to melt, while the clothes clashed with ice like coats of mail. The waves froze solid as they dashed upon the shore. Fortunately, the next afternoon the vessel was reached in safety.

But those on board, it was then discovered, had suffered hardly less severely:—"Stones from the mountain had been blown on board. The cable had parted during the night, and the ship was driving ashore. They endeavoured to cut the mainmast, but could not do so. They were forced to steam out of the bay, and even then nothing could have saved the ship had she not proved herself remarkably seaworthy. On the 23rd it blew another storm, but not quite so strong. But the vessel again lost an anchor, and, driving ashore, bumped on the rocks four times with terrific force. By steaming full speed ahead they contrived to get her off, but a boat was smashed to atoms, and they had to steam for shelter to the other side of the bay, and to moor the ship with ropes to the edge of the glacier."

There good shelter was found, and three members of the staff were permitted to go ashore for the purpose of climbing the great glacier. They were not able to reach the top, although they attained some 2,300ft., and made several valuable discoveries. Near the bottom of the mountain they lighted on a quartz outcrop, which looked as if it contained gold! This was on Sept. 27. What has happened to the brave little band since then will not be known till January next. They are shut up in the ice, and are, it is to be hoped, all well, and carrying on successful explorations. The *Southern Cross*, meantime, has returned to warmer latitudes; but when the ice breaks up will steam again to Cape Adair for intelligence of those she left behind amid the silence of the snows.—*Westminster Gazette.*

There are over 2,550 locomotives on the Midland Railway, from 80 to 90 per cent. of which are worked every day.

BROWN'S PATENTED HOSE COUPLING.

THE train-pipe hose coupling has been tried on passenger coaches and freight cars; it works nicely. No more angle cocks cut off by tramps or other persons, as this does away with angle-cocks entirely. The device consists in the combination, with an air-brake coupling-valve having its stem extended beyond the coupling-head of a valve-setting lever, having an eccentrically-arranged fulcrum, through which it is directly connected with the projecting portion of the valve-stem, to operate in bearing contact with an outer portion of the coupling-head, so that in one position of said lever the valve will be unseated and locked against a closing or seating movement, and in the other position of the lever the valve will be free to seat automatically when the two coupling-heads are separated.

Fig. 1 is a side elevation showing the hose coupling and a portion of a train-pipe, to which the hose is directly connected without the interposition of the usual angle-cock. Fig. 2 is a plan of the same. Fig. 3 is a vertical transverse section through the valved portions of two disconnected coupling-heads, showing the lever of the coupling-valve so set as to prevent the valve from seating, and Fig. 4 shows the lever of the valve in the other head, set to permit automatic seating and unseating of that valve.—*Locomotive Engineering*, N.Y.

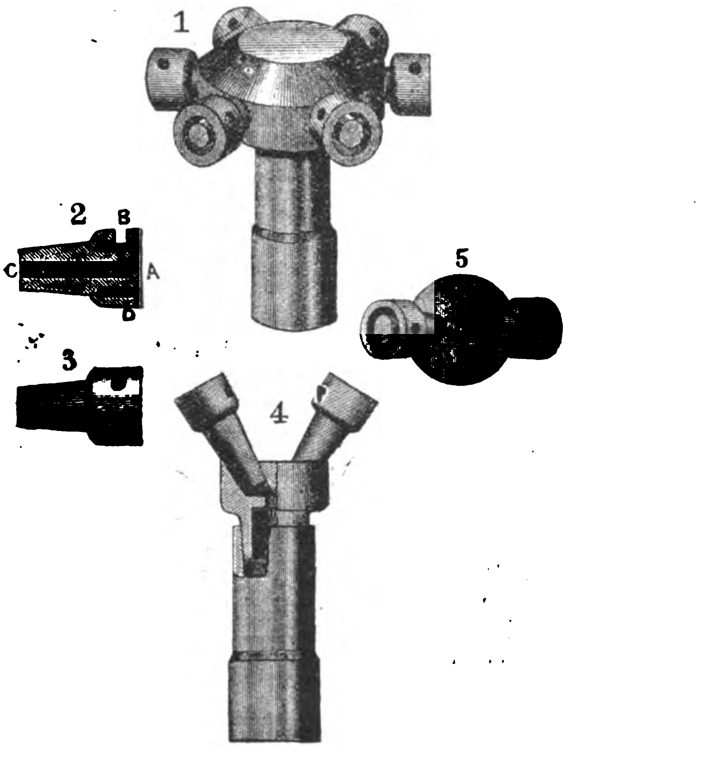
A STUDY OF THE GAS-ENGINE.

AMONG the scientific studies of gas-engines one is contained in three papers by Prof. E. Meyer, contained in recent issues of the *Zeitschrift des Vereines Deutscher Ingenieure*, and based upon experiments made with a Deutz Otto engine in the mechanical laboratory of the Technical High School at Hanover. In these tests the engine was so arranged that different degrees of compression could be employed, and the mixture of air and gas were varied and the motor operated at different speeds in order that comparative determinations of the influence of these elements might be obtained. After discussing the calorific value of various fuels, and describing the methods of calorimetry used in testing the fuels employed, Prof. Meyer goes on to examine the method of computing the heat balance of the gas-engine, deducing the equations by which the distribution of heat may be computed, and showing the method of their application. Broadly speaking, the total heat may be divided into three portions, one of which appears as effective work, one as an increase in temperature of the water in the cylinder jacket, and the third goes out with the exhaust gases.

It is not always easy to determine the exact division of the heat losses; but by careful measurement of the volume and rise in temperature of the jacket water and by brake measurement of the effective power exerted by the engine, the remainder may safely be assumed to represent that portion which is rejected with the exhaust. When, however, it is attempted to so modify the action that a greater portion of the rejected heat may be converted into work, it is necessary to understand the principles which control the heat distribution if improvement is to be expected.

Thus, if an attempt is made to diminish the rapidity of circulation of the water in the jacket, or in similar manner to reduce the proportion of heat carried off through the cylinder walls, it will be found that in general, the only effect will be to increase the proportion rejected with the exhaust gases, the thermal efficiency remaining about the same. An examination of the diagram of the cycle of operations which takes place in the cylinder, however, in connection with the thermodynamic analysis, shows that an increased compression of the explosive mixture should result in an increased efficiency, and it was to demonstrate the truth of this point that many of the experiments were made.

The engine used in the experiments was one of the ordinary Otto type, with the exception that the piston-rod was made in two parts, one portion sliding within the other. By use of a clamp and set of split bushings it was possible to alter the length of the rod without altering any other conditions, and thus the degree of compression could be varied and corresponding trials made. A carefully calibrated Prony brake enabled the effective power developed upon the shaft to be measured, and both the gas and the air entering the cylinder were carefully metered. Thermometers reading to $\frac{1}{10}$° C. were placed in the admission and discharge pipes



for the jacket water, the volume of cooling water being determined in calibrated tanks. The indicator by which the diagrams were taken from the cylinder was provided with a water-cooled stopcock, so that diagrams could be taken continuously without excessive heating of the instrument, and the temperature of the exhaust gases was measured by means of a specially constructed pyrometer of the Le Chatellier type.

The results of these very complete trials are fully tabulated in the paper of Prof. Meyer, and to the original memoir the interested reader must be referred. The general advantage of compression, however, will be seen from the following condensed statement of the average results of trials with four different degrees of compression; all being made with a gas of a calorific power of about 4,700 calories.

The consumption of gas per indicated horse-power when the mixture was compressed to 24 per cent. of its original volume, was 533 litres; when compressed to 25·8 per cent., 559 litres; when compressed to 31 per cent., 624 litres, and when the compression was to only 37 5 per cent. of the original volume the gas consumption per horse-power was 738 litres. There was thus an increase in gas consumption of 38 per cent. in the last case as compared with the first.

STEWARD'S ACETYLENE GAS-BURNER.

ACETYLENE gas possesses so many advantages for isolated lighting that it is little wonder the industry is constantly progressing, and is now on a sure foundation. One source of trouble which consumers have had with the new illuminant has been that owing to the great richness of the gas it was not possible to provide burners which would consume more than one cubic foot of acetylene gas per hour without smoking and consequent loss of luminosity. This difficulty has been obviated in a new acetylene burner, invented by D. M. Steward, of Chattanooga, Tenn., by the grouping of any number of flames on one-burner and by a new air-mixing device. Our engraving, says the *Scientific American*, shows the constructions of the burner. The pillar does not differ from those in general use. At the upper end of this pillar is fitted the head of the burner proper, which is made of lava or other similar substance. The burner stems extend from this head and diverge from each other. They are arranged in pairs, and the jet openings in each stem are adapted to direct the jet towards that at the adjacent stem. Each stem is of cylindrical form, and is made slightly tapering, with the smaller end fitting into the openings in the head and its larger end surmounted by a burner tip former by an annular cup-shaped flange, D, and extension, A, in which the discharge-opening is drilled. An opening, B, is drilled through the flange opposite the opening from the tube proper, C, which conveys the gas to the tip (see Fig. 2). Opening, B, in the flange is of larger diameter than that in the centre wall of the burner. This plan provides an air-space between the extension A, which terminates the end of the gas-tube C, and the interior of the flange, so that as the gas is discharged from the opening it will suck the air into the air space, and so provide for uniform admixture of the air with the gas discharged through the aperture in the flange. The air-mixing device is a unique feature of the burner, and is an improvement on all previous burners, the old method being to surround the jet of gas with a number of small inlets or holes for air. In the new burner the cup-shaped cavity provides a sufficient amount of air, and keeps the burner cooler than with any other known construction.

The tips are so arranged that the two jets are directed towards the jet from the adjacent tip, and inwardly in oblique position. The jets so discharged from each tip commingle with the jets discharged from the adjacent tip on each side so as to form flat flames. The head being located between the pillar and the burner stems, the pillar is kept from becoming heated.

ACETYLENE FOR LANTERN AND ENLARGING.*

THE various kinds of lighting hitherto employed enlarging and projections are in a decreasing order: electricity, oxygen mixed with gas, ether, or petroleum, gas alone, petroleum. In permanent installations a light is employed in the absence of electricity, with oxygen as base. Oxygen is somewhat expensive, and, besides, requires a rather complicated apparatus, in consequence of which it is rarely employed by the amateur photographer, who, not having to illuminate big screens, usually adopts petroleum or gas. Certainly this light does not give him perfect satisfaction, but as there is nothing better he does not complain.

Like most amateurs, I had utilised coal-gas, but owing to several accidents I determined to change my system of lighting, and made some experiments with acetylene. For such experiments it is well, firstly, to investigate the degree of safety of the luminous sources placed in competition, and we have all the elements of comparison.

We know that petroleum, both in the state of lamp oil and of spirit, has caused and causes daily accidents which are often fatal, due, it is true, as much to the carelessness of consumers as to the dangerous character of this mineral oil. The misdeeds of coal-gas are so common that we need not mention them. The oxy-hydrogen, oxy-calcium, and

Oxy-Ether Lights

all require great precautions. Everything considered, acetylene presents fewer chances of explosion than some of the enumerated systems of lighting, and it is not more dangerous than the remainder.

For example, the admixture of oxygen and hydrogen, which gives the brilliant and hot Drummond light, demands great care. Explosions of oil-cans caused by carrying a light in their vicinity occur daily, as with coal-gas, so that comment is needless. Certainly acetylene is not free from these dangerous characteristics, but it reveals its untimely presence by a peculiar odour which warns of danger. Thus the new gas gives a sufficient number of guarantees to justify its admission into the photographer's studio.

If from the point of view of safety, acetylene does not leave the other styles of lighting far behind, such is not so as regards quality and intensity of flame. With coal-gas all the rays of light are not utilised; the flame almost reaches the top of the glass protecting it, and we know that in a magic lantern the only useful light is that near the axis of the lenses. It is for this reason that one seeks before all else a powerful source of light with the smallest possible area. Acetylene beneficially fulfils this important condition.

For projection a row of five burners can be employed, giving 150 litres of acetylene per hour, which is equivalent to a minimum of 20 carcels. The burners are situated one behind the other, like the multiple burners of the petroleum lamp. Owing to this arrangement, the flame is not high, all the light being concentrated at a slight distance around the optical axis. For requirements of an amateur lanternist a row of three burners, 30 litres each, amply suffices. With the 12 carcels thus obtained, a sufficient light can be projected over a circle of 1 metre in diameter. The pictures are brilliantly illuminated. Their dimensions could be enlarged, but it is sufficient if we consider that the amateur will have a limited number of spectators, and that the ordinary dimensions of our rooms hardly admit of having the necessary retreat to cover a

Larger Surface.

On the other hand, the three-burner row gives a luminous power which, when enlarging, allows of considerable shortening of the time of exposure. Even failures are to be feared unless somewhat dense negatives are employed. With a five-burner row exposure would be too much curtailed, and results would not be good on account of the very rapid printing of the sensitised surface.

It being granted that we seek before all else a great luminous power during a relatively short time, no other apparatus seems so fitted for this style of work; besides, management is most simple, and when full there is no fear of a dangerous amount of gas, provided, of course, the operator is prudent. A point not to be neglected is the cheapness of this valuable apparatus, which will contain 750 grammes of carbide, producing 225 litres of acetylene, which represents more than two hours' burning for three burners. In fact, with the lantern, and particularly in enlarging, the time of work is little more than an hour, and it is not necessary to completely fill the metal basket with carbide.

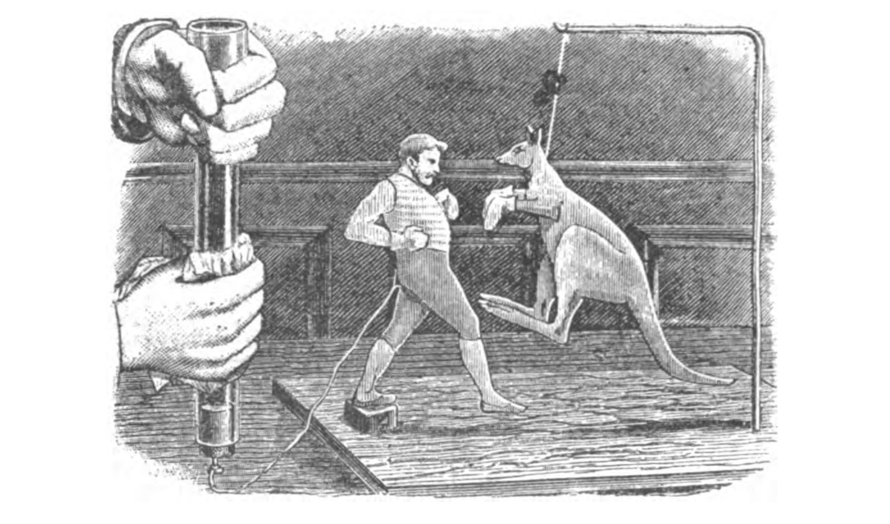
In addition to better light, expenses are less with acetylene. Certainly oxy-calcium, oxy-hydrogen, oxy-ether, and electric lights are more powerful than acetylene, but they are very expensive. On the other hand, it is useless to make a comparison with petroleum, which gives a relatively feeble light of dubious quality. Comparison is only practical and interesting between acetylene and coal-gas. To obtain the 20 carcels mentioned above—obtained by the horary combustion of 150 litres of acetylene—a minimum of 2,000 litres of coal-gas have to be consumed. The 150 litres of acetylene gas are obtained with 500 grammes of calcium carbide at a cost of 65 centimes per kilogramme—i.e., 32½ centimes. The average value of 2 mètres of coal-gas is 60 centimes; whence an economy of 27½ centimes per lighting hour.

To demonstrate the superiority of acetylene, we (*Le Journal de l'Acetylene*) must mention the enormous heat which the 2 mètres of gas would give required for the carcels in the narrow limits of a magic lantern. We could find other arguments, make other comparisons, to the advantage of acetylene. Amateur photographers, without doubt, will wish to ascertain by experiments that the new easily-made gas is more economic and just as safe as its predecessors. Once convinced of this, lanternists will have no other light than this, the discovery of which should be regarded as a god-send for the art of photography.

* From the *Optical Magic Lantern Journal and Photographic Enlarger.*

HIGH EXPLOSIVE SHELL AGAINST ARMOUR.

THE "Isham shell," charged with a high explosive, is said to have produced good effect against armour last month in America. A steel shell unfused, weighing 1,900lb., containing over 129lb. of dynamite, was projected by a charge of brown prismatic powder against a "Harveyed armour-plate, striking it at an angle" more unfavourable than would generally occur on service. The armour, which was better supported than that on a ship's side, was broken to pieces and scattered, the shell itself being blown into fragments, of



which the largest found weighed 4lb. It is difficult to say what conclusions are to be drawn from this trial. Clearly this shell is one of special length and magnitude. The largest gun in the United States navy is 13in. in calibre, and its projectile weighs only 1,100lb., and 1,900lb. fired from such a piece would be what has been termed a double shell or torpedo shell, and the question arises as to what are its shooting powers. Such a projectile might have great value for short ranges, but we do not know the thickness of the armour-plate attacked. We should suppose that the idea is the destruction of the lighter parts of a ship by special double projectiles carrying enormous charges of high explosives. Armour has hitherto entirely defeated shells which explode before obtaining a considerable measure of penetration; but it has always been possible to destroy their plating with explosive shells of disproportionate power. This appears to be a trial of the feasibility of realising the same effect on a larger scale. We should expect the plate to be at least 5in. thick, because it is stated to be a Harveyed plate, and the Harvey process is rarely of practical value applied to thinner plates, which are apt to be contorted in hardening the face. The conditions of this trial are novel, the charge and projectile being enormous. There is nothing surprising in a 5in. or 6in., or even heavier plate, being destroyed by it. Unless the plate was a very heavy one, it means that the heaviest gun was employed against armour which was very greatly outmatched, and the shell is a formidable one to carry. It would be interesting to test the result of such a projectile being struck by a shot when lying in a gun position in the course of supply on board ship. We imagine that care would be taken not to have several brought near together. In short, while the experiment is novel and interesting, we need to know the thickness of the plate, the shooting powers of the projectile, the firing charge which can be used with it, and the arrangements as to supply and handling on service. Happily very little is kept dark in America, so we may hope to obtain the information we seek before long.—*The Engineer.*

THE BOXING KANGAROO.

THE electric pendulum consists of a very light ball of pith, which is suspended by means of a silk thread from an iron wire that is bent at right angles, the longer leg of the angle being placed in a glass foot for the sake of insulation. If the little ball is approached by any object charged with electricity, it is at first attracted, and then, upon being touched, is repulsed. The accompanying illustration, from *Illustrirte Welt*, shows an original way of presenting this old principle. The figure of a boxer is cut out of a card and covered on the back with tinfoil, a little larger than the figure, so that it can be turned over the edges of the card. One foot of the figure is stuck into sealing-wax on a small block, and to the back of this leg is secured a piece of iron wire. As the other foot does not touch the support it is insulated from it. The figure of a boxing kangaroo in position for making an attack is cut of tracing-paper. This figure is also covered on one side with tinfoil and then is suspended by a linen thread from one end of a piece of iron wire that has a rectangular bend, the other end being set in the supporting plate so that the kangaroo shall face the boxer. To obtain the necessary electricity, we take a glass lamp-chimney, stop one end of it by means of a cork, and in the centre of the cork drive a nail, to which is secured one end of a piece of small iron wire, the other end of the wire being connected with the wire on the back of the boxer's leg. After the lamp chimney has been carefully dried, it is rubbed with a piece of silk or fur, thus generating electricity, which is transmitted to the boxer. The kangaroo is strongly attracted by the figure thus charged with electricity, which it attacks, but a discharge of electricity takes place at once, and the animal is repulsed. This is followed by a series of attacks and repulses, the struggle between the man and beast being constantly renewed as long as the rubbing of the chimney is continued.

CYCLE CONSTRUCTION.

A VERY interesting question is raised by the long crank bicycles now coming into favour. The matter cannot be considered as one of pure mechanics, since from this point of view it is obvious that a 6½ crank with a 65in. gear is identical with an 8½ crank and an 85in. gear. In practice, however, riders find that a given distance is ridden much more easily with the second arrangement than the first, a circumstance which points to the conclusion that the principal cause of the fatigue felt is the wear and tear of nerve rather than of muscle. This view is that held by Mr. R. E. Crompton and his son, to whom cyclists are principally indebted for the commercial introduction of the innovation, though, as the Messrs. Crompton quite properly admit, they have themselves been largely indebted to Mr. Otto Blanthy, of Buda-Pesth. Messrs. Crompton suggest that the nerve waste involved in riding is proportional to the number of times the muscles are energised—i.e., to the number of pedal strokes made, and this view seems certainly borne out by the experience of riders who have given the long-crank machines a fair trial. Riders who have done much hard riding with short cranks, it should be observed, find considerable difficulty at first in accommodating themselves to the longer pedal. This arises from the fact that they have become more or less muscle-bound. The great development of the muscles used in pushing down the pedal, and the shortness of the stroke made, leads to a shortening of these muscles, which then find a difficulty in making the longer stroke needed with the long cranks. Messrs. Crompton have also recognised what they call a muscular elastic limit. If the muscle is called upon to exert a force greater than a certain limit, which differs with the individual, it very rapidly becomes tired, and is only restored after a prolonged rest. This limit, according to the experiments of Messrs. Crompton, corresponds to an average pressure on the pedal of 100lb. for weak individuals, and to one of 140lb. for exceptionally strong men. The principal resistance experience by a cyclist on the level is that due to the air. This is strikingly shown by the recent experiment in America, in which a cyclist succeeded in covering a distance of a mile in little over 57 seconds, by following close behind a locomotive fitted with wind screens, which permitted the rider to run in practically still air.—*Engineering.*

THE copper production of the United States in 1898 was the largest on record, and reached 535,900,232lb., of fine copper, an increase of 6·8 per cent. over 1897.

SCIENTIFIC NEWS.

THERE does not appear to be much probability that Holmes's comet will be observed at this return, except through powerful telescopes; but it may be useful to publish an ephemeris by Herr H. J. Zwiers, which gives a position for Sept. 13 G.M.T. (12h.), R.A. 3h. 8m. 52s., N. Dec. 43° 3′ 34″, and for Sept. 30, R.A. 3h. 7m. 29s., N. Dec. 46° 26′ 25″. The comet is well situated, but is very faint.

The new observatory with the great refractor erected at the Astrophysical Observatory, Potsdam, has been formally opened in the presence of the German Emperor.

A fourth edition of Mr. W. Thynne Lynn's "Remarkable Eclipses" has been issued by Mr. E. Stanford, and will be found useful, as it contains information as to forthcoming eclipses, notably the solar eclipse of next year.

An article on Clouds, with reproductions of photographs, by MM. Antoniadi and G. Mathias appears in *Knowledge* for this month, and will be found of especial interest by meteorologists and those who have studied the Rev. W. Clement Ley's work on "Cloudland." Mr. W. S. Bruce has an article on "Ben Nevis and its Observatory," illustrated by the author, who was formerly in charge; and the Rt. Hon. Sir Edward Fry and Miss Fry continue their interesting account of the Mycetozoa.

Sir Howard Grubb, F.R.S., has issued a catalogue of astronomical instruments, observatories, &c., which will be appreciated by observers all the world over, because it is a great deal more than a mere catalogue, as it contains photographs of nebulæ, eclipses, &c., to show what can be done by modern optical apparatus.

It is announced that an Austrian party will visit India (Delhi) to observe the Leonid meteors during October and November. Two stations, about five miles apart, will be connected by telephone.

The arrangements for the meeting of the British Association at Dover are practically complete, and it is satisfactory to note that the railway companies are offering return tickets at reduced fares from Sept. 12 to Sept. 27.

Although Lord Kelvin has resigned the chair of natural philosophy in Glasgow University, which he has held for half a century, he will not sever his connection with his scientific pursuits, and in all probability will be present at Dover to take an active part in the meeting of the British Association.

Capt. Wellby, who has returned from his expedition into the unknown portions of Abyssinia, has given an interview to Reuter's representative, and the following notes may be interesting concerning the "giant tribes":—"They were very friendly. They were quite naked, and both men and women were most powerfully made; they were not of a negro type, and some were good-looking. Their colour was something between copper and black. All the men have long hair down to their waists, and this is arranged in the form of bags, in which they stow their various trinkets, &c., they carry about with them. Round their necks they wore a large number of iron rings of enormous weight. These were placed one upon another until the unfortunate native was scarcely able to move, and had to walk with his chin elevated in the air. It resembled nothing so much as what has been called the 'masher collar.' They are very fond also of wearing rings of various kinds round the arm. For this purpose they wanted to cut off my mules' tails, but to this I naturally demurred. The women are not bad-looking; some are even pretty, and they are always laughing and full of fun. Curiously enough, they have not long hair, their coiffure consisting merely of a collection of ringlets. Each family has its own little village, surrounded by a zariba. The people always carry spears and a sleeping pillow, though when they approached me they covered their spear-tips with bits of leather, as evidence, I suppose, that they did not want to fight." Round Lakes Hora and Lamini the explorer found an incrustation looking like salt; this he found the natives collected and sold for grain. He has brought samples of it with him to London.

The death is announced of Grace Anne, Lady Prestwich, who was married to the late Sir Joseph Prestwich in 1870, and was left a widow

in 1896. She was a daughter of Mr. J. Milne, of Findhorn, was the author of several novels, contributed articles to various magazines, and was much interested in geology, having assisted her uncle, the late Dr. Hugh Falconer, F.R.S., in his investigations of some of the ossiferous caverns of Sicily. She was of material aid to her husband in the preparation of his standard work on geology, published by the Clarendon Press.

In a memoir presented to the Paris Academy of Sciences M. G. Burgess describes a method of determining the Newtonian constant, in which the Cavendish method is modified by supporting the weight carried by the thread in a pan of mercury. The principal difficulty in this method is found in the necessity of keeping the temperature of the mercury constant. The method is worth the attention of those whose business it is to aim at absolute accuracy, and attain it if possible.

Dr. Hamilton Wright, formerly of Montreal, is to take up the study of beri-beri in the Straits Settlements. Dr. R. Fielding Ould, of the Liverpool School of Pathology, has been sent out to join Major Ross at Sierra Leone in the study of Tropical diseases, especially the cause of malaria. Major Ross, in a second letter on the subject, says:—"In my last I told you that I had found a malaria parasite in an *Anopheles* from the asylum at Kissy, where there had been an outbreak of fever. We now turned our attention to the 3rd West India Regiment stationed at the suburb of Wilberforce, where they are suffering severely from fever. On going there we found all kinds of parasites in the patients in hospital. At the same time, we discovered that the only form of mosquito which is plentiful there is a large species of *Anopheles*. We caught a number of these in the hospital and barracks. Out of 13 examined we have found the malaria germs in no less than four, which amply accounts for the fever at Wilberforce. It was, however, necessary to make a definite experiment by actually feeding an *Anopheles* on a case of malaria, and examining afterwards. This was done on the 17th. The insect was dissected yesterday and found to contain malaria germs growing in its tissues. Hence there is no longer any doubt that that kind of *Anopheles* carries malaria . . . . The parasite which I have cultivated is the quartan one, which has never been cultivated before. We are all perfectly well up to date. I am looking round as to sanitary details, &c., as Mr. Jones suggested. Austen has discovered the tsetse-fly here. This is a matter of very considerable importance."

The following rather curious paragraph appeared in a penny London morning paper: "A strange complaint which has lately been prostrating large numbers of Parisians has been attributed by medical men to a rather peculiar cause. This is the presence in their patients' morning rolls of salts of lead, deposited on the floors and walls of the ovens in which they have been baked. According to the medical theory, the extensive use of old timber in place of other fuel that so largely obtains in France is directly responsible for this condition of affairs. As a result, the Paris Council of Hygiene has issued an edict forbidding the employment by bakers of wood from old houses, disused railway sleepers, or wooden paving-blocks for their furnaces. Such timber is usually impregnated with sulphate of copper or creasote, and poisonous volatile salts are liable to rise from it when heated." It is not explained whence the salts of lead come from in the case of wood treated with blue copperas or creasote.

A "cloud burst" is reported from Cwm Avon, at Pontrhydyfen, that washed many thousands of tons of earth down the mountain side into the canal, which burst its banks.

The alarmist statements about the London water supply during the long drought will be studied in connection with a statement by Mr. Benjamin Taylor in the *Engineering Magazine* for September regarding the Glasgow water supply. In Glasgow, it is stated that a £16 householder obtains for 71d. per annum a continuous, never-failing, unrestricted stream of the purest water in the world. It is calculated that 380 gallons of pure water are delivered to the citizen of Glasgow for every penny paid. And it is water of such peculiar softness that the householders of Glasgow can pay their water rate out of what they save on soap. Loch Katrine water is not only soft—it is remarkably bright, clear, and free from vegetable matter. It is uniform in colour, temperature, and quality, and is absolutely free from pollution, and must remain so, because the corporation have now bought up the building rights of the whole drainage area; it needs no filtration, and is practically unaffected by the change of seasons.

It is stated that kingfish (Opah, *Lampris luna*) is on exhibition in the Midlands (rather a wide address). It was caught recently in the North Sea, and is somewhat like the sunfish, being without teeth and living by suction. It has bright red fins, and no fewer than 22 colours can be traced on its back. It is a native of Eastern seas, and is held sacred by the Japanese.

The Royal Mound of the Hill of Tara, County Meath, on which for a thousand years the kings of Ireland were crowned with great pomp and ceremony, has, in the words of the Rev. Dr. Healy, rector of Kells, been "destroyed beyond the possibility of restoration." A gentleman hoped to find the Ark of the Covenant buried beneath the mound, and the landlord permitted the excavations. The Board of Works had no legal power to prevent the work of destruction.

The new explosive invented by an American scientist is exciting a good deal of interest in the United States. It is said to be more destructive than dynamite, and less dangerous to handle than any high explosive now in use. It is also claimed for it that it does not give off the slightest particle of smoke, nor does it contain either nitro-glycerin or nitro-cellulose. The United States Government is carrying out some elaborate experiments to test its merits practically.

USEFUL AND SCIENTIFIC NOTES.

"CASSIER'S MAGAZINE" is an "electric railway number," and will be found very interesting by all who are studying the coming means of locomotion. It is illustrated with numerous representations of electric railways and plant in practically all parts of the world—certainly in all parts where electric railways have gained any position.

IT is said that the application of heat accumulators on the locomotives of the Moscow-Koursk line of the Russian State railroads has given excellent results, allowing of the increase in weight of trains from 15 to 25 per cent. The apparatus consists of a cylindrical reservoir of cast iron, with a capacity of about 300 gallons, placed horizontally on the top of the boiler, and communicating with it by pipes and valves. During stops, or in runing down gradients, when little or no steam is consumed, it is used to heat the water in this reservoir, which is then used for the feed.

ACCORDING to a Simla correspondent of the *Pall Mall Gazette*, a scheme is now maturing for the provision of an electric railway in the Himalayas, the power for which is to be provided by the mountain streams. The line would start from Pathankot, proceed up the Kangra Valley to tap the tea industry, thence cross to Mundi on the Beas River, whence it goes to Bilaspur, on the Sutlej, where the chief installation of water-power will be situated. From there it will be taken on to join the Simla-Kalka Railway, the place of junction being most probably somewhere about Kalka, a total of some 250 miles.

SOME interesting experiments on the corrosion of metals by sea water have been carried out at Kiel during the past two years. The plan followed was to cut off twelve specimens of the metal to be tested, of which three were kept as "witnesses" whilst the other nine were placed in salt water. At the end of eight months three of the latter were withdrawn and compared with the "witnesses." Eight months later a second set were withdrawn and a fresh comparison made, those then left being taken out after the lapse of a third period of eight months. The metals tested included alloys of copper rich in zinc, bronzes containing little zinc, bronzes containing no zinc, pure aluminium bronzes, and finally bronzes containing aluminium and zinc, or zinc and iron. The latter in particular showed remarkable resistance to the corrosive powers of sea water, being practically untouched at the end of a two years' immersion. The alloys containing zinc, however, gave much less favourable results. The copper-tin alloys and copper-aluminium alloys and the iron bronzes resisted perfectly when immersed in sea-water in contact with iron. The bronzes containing iron, when placed in contact with those of tin, showed a loss by corrosion. It is thus important, if corrosion is to be prevented, to avoid placing these alloys in contact with metals electro-positive to them.

LETTERS TO THE EDITOR.

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

A POWERFUL MAGNET—SHIFTING (?) OF THE TERRESTRIAL POLES—DARWIN AND THE DELUGE—THE STEREOSCOPE — FIGURE OF THE EARTH — VELOCITY OF LIGHT—GRAVITY—FIXING GNOMON OF SUN-DIAL—SATURN—ENCKE'S COMET—A MAN OF MANY MEDALS—PROF. PICKERING'S NEW PHOTOGRAPHIC TELESCOPE—THE BRITISH ASTRONOMICAL ASSOCIATION AND THE ROYAL ASTRONOMICAL SOCIETY—RIGEL—INCLINATION OF PLANETARY POLES—THE ASTRONOMICAL TRIANGLE.

[42776.]—I REMEMBER that the Earl of Crawford, when he was yet Lord Lindsay, had in his laboratory somewhere in Soho, an electro-magnet of enormous power, which would bring a metal candlestick flying across the room; but this remarkable instrument must have paled before that of Dr. Haab (to which you refer in your "Scientific News" on p. 36) which "is strong enough to draw a nail from a board!" The *Morning Leader* apparently has omitted to mention the length of the nail and the thickness of the board.

"Little Bookham" (letter 42721, p. 40) is quite obviously muddling up the Southern Magnetic Pole with the southern pole of the earth's axis of rotation. The shifting of the earth's poles has been adduced over and over again in attempts to account for changes of terrestrial climate, floods, and goodness knows what and all; but the most elementary dynamics will show its impossibility. Did "Little Bookham" ever hear of an instrument called the gyroscope?

Mr. Dormer calls attention (in letter 42723) on p. 40 to what, if not an absolute piece of controversial dishonesty, is certainly the merest effort to argue for victory, when he speaks of Darwin's total change of views as to the extinction of species by cataclysms. It would be just as defensible to quote the late Dean Buckland's "Reliquæ Diluvianæ," published in 1823, as the outcome of that well-known geologist's mature views as it is to appeal to Darwin's earliest utterances as decisive of the conclusions to which he was led by more extended research.

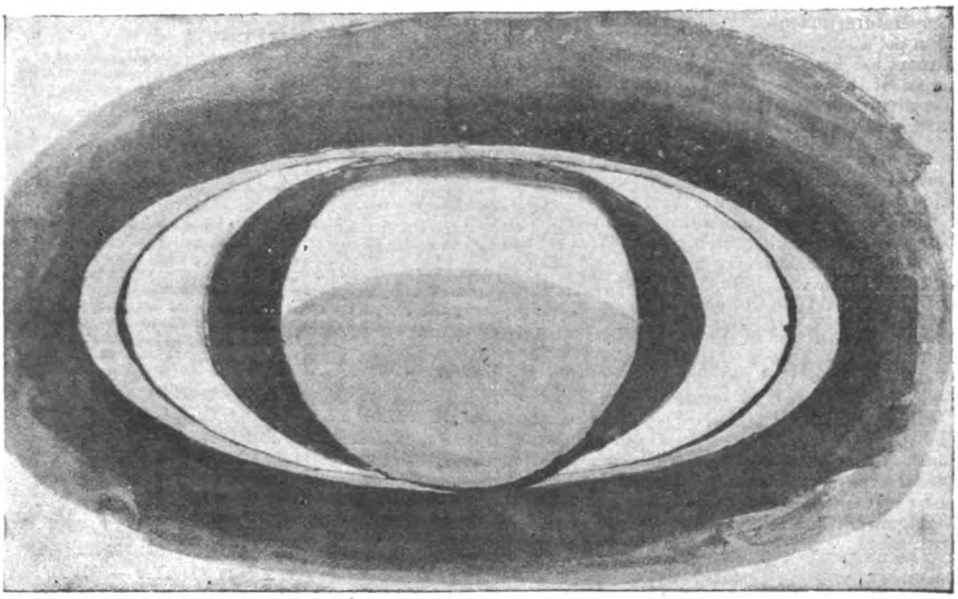
While fully appreciating the spirit which has prompted Mr. Kelly to write letter 42762 (on p. 66), I would invite his attention to what is said by an eminent church dignitary and theologian (I mean Dean Farrar) in "The People's Bible History":—"The faintest semblance of harmony between Genesis and physical science can only be obtained by a licentious artificiality and casuistry of exegetic invention."

Letter 42742, p. 43, suggests to me to express my regret that the reflecting form of stereoscope has been so entirely superseded by the lenticular one. I always thought that it exhibited objects in stronger relief than that with eye-lenses, and it had the manifest advantage of admitting the use of very large pictures when necessary.

"J. D." (query 96506, p. 46) is so far right that when the earth was in a gaseous form it did not present, or may not have presented, its existing oblate spheroidal form; but as soon as ever it became viscous, its existing rate of rotation would produce exactly the amount of equatorial protuberance which it now exhibits. The proof is a purely mathematical one.

In reply to query 96520, p. 46, light of every wave-length travels *in vacuo* with identically the same velocity. Otherwise we should have all the stars and planets exhibiting prismatic colours. It may be taken that such velocity differs very little from 186,326 miles per second. Pitch is not supposed to make any difference in the velocity with which sound is propagated through the air.

Mr. Alexander asks (in query 96538 on p. 47) what is meant by the instantaneous propagation of gravity? and whether this signifies that it acts so



quickly through great distances that its velocity is incalculable? Well, substantially this last form of expression is correct, for if the action of gravity were not practically instantaneous, the earth's path round the sun would become a spiral instead of being as it is, a re-entering curve, and the year would increase in length. I have said in the preceding paragraph that the velocity of light in vacuo is 186,326 miles per second, so that it takes light over eight minutes to come from the sun to the earth. Now, suppose that gravity were only propagated at this rate, then the earth would feel the sun's pull rather more than eight minutes after she had been in the place where the sun began to exert it. In other words, the pull would not be in the direction of the straight line joining the sun and earth when the pull was felt, but in that of the line connecting these two bodies between eight and nine minutes before. This would increase her velocity and what is popularly known as her "centrifugal force," and so she (*very* slowly) would move outwards, and the diameter of her orbit and her year would lengthen.

"Nauticus" (query 96543, p. 47) can cement his brass gnomon on to his slate dial by stirring freshly-burned plaster of Paris into melted resin, and adding enough boiled oil to bring the whole composition to the consistence of honey; but I should rather recommend him to retap the screw holes and get new screws or pins. I have cemented a gnomon on to slate with plaster of Paris to which alum has been added. It should be dry and hot before water is added to it.

After reading query 96547, p. 47, I turned the telescope upon Saturn, and have represented everything that was visible with a power of 260 in the subjoined very rough sketch. Definition was, of course, unsatisfactory. Had I not known of the existence of the crape ring, I should not have detected it.

I do not understand why "W. S." puts query 96549 (on p. 47), inasmuch as the last perihelion passage of Encke's comet did occur on May 24, 1898.

Many of those who will read these lines will remember how the late Mr. A. Cowper Ranyard was instant, in season and out of season, in his protest against the award of medals as a form of recognition of the value of scientific work, and how earnestly he tried to deprecate such awards in the case of the Royal Astronomical Society. I wonder what he would have said to the reception of a *ninth* medal by that astronomical veteran Dr. Lewis Swift, who has just been the recipient of the Donohue Comet one from San Francisco for his latest discovery. Of these tangible testimonies to the value of his unwearying work, Dr. Swift himself says: "The medal arrived safely last night, increasing my number to nine. . . . Three are of gold, one of silver, and five of bronze. Those of gold were awarded by the Academy of Sciences at Vienna, Austria. The silver was included in the Lalande prize of 540 francs, awarded by the Academy of Sciences of France, and 500 francs in cash and the medal. The large bronze medal and 125dol. from the Royal Astronomical Society of England, being the first award from the 'Mrs. Jackson Gwilt gift,' which causes me to prize it more highly than even the gold ones. The four others of bronze are all alike as to size and design, and were bestowed by the Astronomical Society of the Pacific, from funds founded by Joseph A. Donahue in 1890." Verily Dr. Swift is a much decorated man.

The surmise in the third paragraph of your "Scientific News" on p. 59 is a correct one. Prof. Pickering's new telescope is nothing but a photo-heliograph of very long focus fed by a siderostat or cœlostat.

The query put by "An Old Printer" (in letter 42746) on p. 60 may conveniently be divided into two parts. Imprimis, then, as to the question of "means." The entrance fee to the Royal Astronomical Society is two guineas, and the annual subscription the same; or an elected Fellow may, after paying the entrance fee, compound for his annual subscription by a single payment of twenty guineas. In the case of the British Astronomical Association the entrance fee is only five shillings, and the annual subscription half-a-guinea, or composition may be effected for six guineas. Thus your correspondent will see that the Association offers facilities to the young astronomer of narrow means, which the older society is perforce unable to afford him. When we come to "qualifications," we get upon more ticklish ground, because there can be no doubt that there are men who write "F.R.A.S." after their names (more or less for advertising purposes) whose claim to be considered astronomers is of the very scantiest, even if it be not nil. A heavy responsibility rests upon every Fellow who signs a candidate's paper "from personal knowledge." I have not seen the morning paper from which "An Old Printer" quotes; but if the writer in it alleges "that no important addition to our knowledge of solar physics has accrued from the observations" made during the Indian eclipse of 1898, he is talking nonsense, pure and simple; and shows a curious incompetence to comprehend the volume which he professes to criticise.

In reply to one question which Mr. Ellison puts in letter 42752, on p. 64, Rigel always has seemed bluish to me. It may perhaps be described as white, but I certainly cannot detect any yellow in it.

When (in reply 96467, p. 70) "J. R. J." asks "*Why* are the poles not all at right angles to the various orbits?" he puts a question which it would require omniscience to answer.

If (of which I am somewhat doubtful) I understand query 96553, on p. 74, "Jancis," if living in a Southern latitude, would work his triangle from the *South* Pole, and hence his co-latitude would = 90° − latitude, and the Sun's polar distance = 90° + his North Declination.

A Fellow of the Royal Astronomical Society.

VARIABLE STAR OBSERVATIONS, AUGUST, 1899.

[42777.]—S PERSEI has been unusually faint, and has varied but little from 9·7 magnitude the whole month.

R Lyncis passed a very bright and well-marked maximum 6·5 magnitude Aug. 9. The interval from the previous maximum, Aug. 11, 1898, was 363 days. The star was then 9·2 magnitude.

R Ursæ Majoris. The light-curve has been very irregular during the last two months, and several rapid fluctuations between 8·7 and 7·6 magnitudes have occurred. The maximum 7·6 magnitude was Aug. 12. The interval since the previous maximum, Sept. 14, 1898, being 332 days.

S Ursæ Majoris. The light-curve during the last three months has been very irregular. The maximum 7·5 magnitude, July 20, was followed by a sudden decline. The interval since the previous maximum, Nov. 6, 1898, is 256 days.

R Camelopardi was 12·7 magnitude Aug. 18, and has varied but little during the month. It is nearing minimum, and very faint, being near the limit of vision with this telescope.

T Draconis has not varied much from 8·0 magnitude during the last six weeks. This is probably about maximum brightness; but the light-curve is so flat that the precise date is difficult to determine.

S Herculis has increased exactly three magnitudes from April 19 to Aug. 23; at the latter date it was 8·6 magnitude. The maximum will probably occur some time in September.

The instrument in use 6·4in. equatorial refractor. Weather has been very favourable, and observations were made on 21 nights. C. E. Peek.

Rousdon Observatory, Lyme Regis.

SOME RED AND RUDDY STARS.

[42778.]—THE following list is a continuation of that published in the "E M." Sept. 16, 1898, page 113, letter 41489, Vol. LXVIII. No. 1747. The stars were observed with Mr. Espin's 17¼in. reflector. The magnitude has been underrated, on account of the moon; but a correction is added for each of the three nights:—

BRILLIANT FIREBALLS.

[42779.]—HOPING to obtain notes of duplicate observations, I give particulars of some of these objects recently seen by me.

1899.	G.M.T.	From	To
	h. m.	° °	° °
August 27	9 15	216 + 38½	201½ + 32½
,, 28	9 30	302½ + 13½	315½ − 5
,, 28	12 35	292½ + 17	301 + 3

The first was as bright as Venus, and moved slowly. The second was trained and traversed its course in about one second; it was equal to Jupiter in brilliancy. The third was also trained; its colour was a brilliant white and its motion slow (duration about 0·5sec.). In brightness it slightly exceeded the full moon, and cast a dark shadow. The shape was somewhat like that of a kite, and the greatest breadth was very nearly 1°. The brightness was the greater in the second half of its course. The three meteors appear to have belonged to the same radiant—270° + 45°.

A letter appeared in the *Daily Mail* of the 26th ult. stating that the writer had seen at 8h. 8m. on the 24th "a falling meteor of unusual size, and of a metallic pale green colour, which fell to the south-east of the Great Bear constellation." The place of observation was not specified.

Further letters on the 28th record that at Blythe, Surrey, "it appeared a little to the south or south-west of Cassiopeia, and fell almost vertically for a short distance"; also that at Frinton-on-Sea the meteor was noticed as "pear-shaped, and with a long tail behind it." A note mentions that the object was also seen at Guildford, Bath, Leicester, Acton, Blackheath, Hatfield, and a score of places in London.

About 8h. 30m. on the same date (24th), a brilliant meteor was seen near the zenith by a friend of mine at Scarborough. Perhaps some readers of

the English Mechanic have recorded more definite observations of these two meteors.

Walter E. Besley.

The Chase, Clapham Common, Sept. 2.

METEOR.

[42780.] — Whilst crossing Blackheath at 9h. 10m. on the evening of Sunday the 3rd inst., I noticed a brilliant meteor, which passed from near α Capricorni to near δ Aquarii in a space of three or four seconds, and then suddenly disappeared; no sparks were seen, and there seemed to be a little haze at the point of disappearance.

Blackheath, Sept. 4. W. T. Lynn.

THE COLOUR OF RIGEL.

[42781]—With reference to the third paragraph of Mr. Ellison's letter in your last issue (42752, p. 63), I append a few notes on the colour of this star.

Webb in "Celestial Objects" (last edition) gives the colour of Rigel as "yellowish white" (from Smyth). He adds, "I always see a blue tinge" in the star. In the 1881 edition of the same work these words are found:—"Struve, however, gives yellowish white; Fletcher, yellow; Sadler, yellowish with reflector, bluish with achromatic, side by side."

Twenty-eight observations by eight members of the British Astronomical Association made Jan. 9 to April 6, 1892, in connection with the star colour section, give the mean colour white. Flammarion also calls the star white; Espin bluish-white. Foulkes says: "white with a tinge of blue." Gregory remarks that "Capella and Rigel have a bluish tint, but do not differ considerably from Sirius, Vega, and Regulus, which are generally referred to as white stars."

For my part I regard Rigel as bluish-white; but Capella as yellow. Walter E. Besley.

The Chase, Clapham Common.

THE MEDIAL TELESCOPE.

[42782.]—Being particularly interested in telescopic matters, I read letter 42758 through two or three times before I could grasp any idea of what the writer is alluding to. I am still much in the dark about the new telescope, and shall look forward to the promised explanation by Mr. A. Caplatzi. I can understand that a lens has to be divided into two; but I cannot think Mr. Caplatzi really means what he says when he states such a *half* lens "does not bring the rays to a focus as the *whole*." I should say the two halves will have the same focus as when they were whole.

With such meagre data it is almost unwise to criticise the idea; but I would ask if the same result could not be got by only boring a suitable hole through the centre of the object-glass, and letting the instrument be a kind of refractor Gregorian; the concave mirror placed in a position to lengthen the focus is Gregory's idea.

I suppose the image, if formed on the focal plane, would require a flat in front of the o.g. to turn the cone of rays at right angles? But perhaps my imagination is leading me astray from the rough data given!

It is plain a reflector is used to lengthen the focus (cribbed from Gregory's telescope), and half an o.g. as the light gatherer, the result being "perfect achromatism." Now, after all these letters of your painstaking correspondent "H." on the Gregorian telescope, it does seem strange anyone should go such a roundabout way to gain "perfect achromatism" in *a kind of* Gregorian telescope, when it is much more simple to follow Gregory, and with the same result—namely, "perfect achromatism."

323, Kirkstall-road, Leeds. David Booth.

GREGORIANS AND "H."

[42783.]—I hope you will allow me a short explanation of some of the points raised by "H." in letter 42757. I have so far expressed nothing but admiration for his abilities, and given no cause for the abundance of sneers with which his letter is interlarded. As to testing small speculum, I do not pretend to ability to do so; but I have had the assistance of an expert workman, and I have asked him to describe his method of testing for the benefit of the English Mechanic; but he declined, on the ground that he would not lay himself open to be sneered at and his methods claimed as already, or to be, included in the intellectual property of another; but he promises to describe it at a future time, when "H." has completed his masterly expositions.

As to his following paragraphs, I have nowhere acknowledged want of either theoretical training or practical experience in telescope making.

That the large speculum has been injured is conclusively negatived by the performance as a Newtonian being uninjured. The conclusion that more injury has been done to it as a Newtonian than as a Gregorian is, therefore, gratuitous, and does credit only to his imagination. I note here that he has just discovered that any defect in figure of large mirror is ten times more injurious in the G. than the N. To ask for the opinion of others about an eyepiece is not to profess ignorance. My measures to minute fractions of an inch stand on the same ground as those of "H." The assertion that *I know* he cannot avail himself of invitation to inspect my telescope is simply untrue. I have no notion of his residence or name. He may be my next-door neighbour. Anyhow, I am willing to show it to him.

I have neither begrudged nor bragged of the expense of alteration; but cost has, nevertheless, in most people's minds, much to do with telescopes. Even a scientist wants something as a result of his labours. As to the opinions he quotes, Parkinson, Coddington, Dr. Robinson, Airy, and Gregory were all, like "H." himself, theorists only; and Lord Rosse took care to make his own telescope a Newtonian. And we may set against these opinions the common judgment of astronomers in favour of the Newtonian form.

I am advised to obtain a diagonal. This is all right for low powers, but it spoils definition with high ones. I am also advised by "H." that an evening in some public observatory would "put me in the way of observing easily at all altitudes." I happen to have observed with a giant, but the comfort was conspicuous by absence. I do not think the explanation *re* the sea-green discs is either ingenious or ingenuous. The stars are not sea-green, yet he used sea-green to calculate upon. I quoted his exact words, and leave the matter; but if he has anything further to write *re* my doings, will he kindly eschew personalities and save space?

I thought everyone knew the meaning of the sentence "Old Printer" (42746) quotes. There are many amateurs who cannot afford the five guineas entrance fee and two guineas per annum of the R.A.S. For them the B.A.A. supplies a tolerable substitute. There are others whose education or local status is insufficient, as the R.A.S. was not intended for shopkeepers, but for gentlemen. There are notorious members of the B.A.A. who would not get a vote for Fellowship of the R.A.S.

Allow me to conclude by expressing my great indebtedness to "H.," and admiration of his abilities and tactics. Ell Hay.

TELESCOPES.

[42784.]—Will readers kindly give me some information on the following subjects? I have in my possession three lenses as follows: one double-convex of crown glass, 6⅛in. diameter by 47in. focus, mounted in a very fine cell as an object-glass, and having a clear aperture of 5⅞in.; one plano-convex of crown glass, 3in. diameter by 3¾in. radius; one plano-concave of flint glass, 3in. diameter by 3¾in. radius. The above lenses are beautiful specimens of workmanship, and by all the tests I have been able to apply they are simply perfect.

A short time ago I mounted them temporarily on a wooden bar, using the 6in. lens as an object-glass and the two 3in. lenses combined as a corrector, and applied an eyepiece of 1in. equivalent focus taken from an old telescope which I had at hand. After much experimenting, I finally placed the lenses of the corrector with their flat sides together—convex side towards object-glass, concave side towards eyepiece. Distance from o.g. to corrector, 26in.; o.g. to first lens of eyepiece was then 62in. With this arrangement the combination seemed to be perfectly achromatic, and the definition on terrestrial objects exceedingly good. I had no opportunity of trying it on celestial objects.

I intend to construct a telescope with these lenses, if it is likely to prove worth while. Will some reader inform me just what results I can expect from it when finished? How will it compare with a regular achromatic of like dimensions? How great a power should I be able to use with it on double stars, &c.?

The only description I have ever seen of such an instrument is in Dick's "Practical Astronomy," published in 1846, in which it is described as the invention of Mr. A. Rogers. Of course, I have no doubt many such instruments are in use, but I have not been able to find any account of them.

According to Mr. Rogers, after the condition of achromaticity is satisfied by shifting the corrector along the tube of the telescope, the spherical aberration may be corrected by slightly separating the lenses of the corrector. Is this a fact in practice? And if so, about how much separation would I be likely to need? I ask this that I may make the mounting of the corrector to admit of the necessary separation.

I have also an old Gregorian by Geo. Sterrop, of London, of the following dimensions. Diameter of large mirror 2¼in., focus 9in.; diameter of small mirror ¾in., focus 1¼in.; field lens ¾in. diameter, 2¾in. focus; eye-lens 1in. focus. The two lenses are 2in. apart. This instrument has not been used for over ten years, but is said to have once been a very good one. The metals are badly tarnished, and the small one is out of adjustment—that is to say, it is not properly centred, although being adjustably mounted. I suppose I could adjust it if other particulars were right? Any information as to cleaning or polishing the mirrors without danger of injury to their figuring, and also regarding re-adjusting the instrument in general, will be thankfully received, as I have not been able to find an optician who knows anything at all about the Gregorian or about metallic specula.

E. P. Clark.

245, West Eighteenth-street, New York.

OBSERVATORY LIGHTS—POWER FROM FALLING WEIGHTS—A FLY PROBLEM AND ANOTHER.

[42785.]—If Mr. Baly, and also "Carliol" (query 96575) will think the matters out seriatim, they will at once see that the idea of deriving power in any considerable quantity from the energy of a falling weight is quite impracticable. One horse-power is developed by a weight of 33,000lb. falling 1ft. per minute. Assume that the 8-volt lamp will require 10 watts to light it, and that to drive the dynamo we use a 56lb. weight. 1H.P. = 746 watts, hence 10 watts is, in round numbers, $\frac{1}{75}$H.P., and to develop this power we would require $\frac{33,000}{75} = 440$lb. falling 1ft. per minute—i.e., 56lb. falling nearly 8ft. per minute, or an hour's light represents a drop of 440ft., not allowing for any loss of power in the dynamo. Here are three methods by which Mr. Baly could light his lamp in a perfectly satisfactory manner: (1) Dispense with the accumulators altogether, and light direct from a small dynamo driven by an oil-motor. Cost of plant, about £6; working cost, ½d. per hour. (2) If a good head of water is available, use a Pelton wheel instead of the oil-motor. Cost of plant, about £4; working cost depends on the price of the water. (3) Use a small windmill to drive the dynamo, and charge the accumulators during the day, as the power will not be sufficiently steady in this case to light direct off the dynamo.

In reply to Mr. Ellison (42752), I may be wrong, and am quite open to conviction; but I fail as yet to see that it makes any difference whether the carriage is roofless or not, or what distance the fly is above it. Without the fly you have the weight of a column of air of a given height. With the fly the same weight plus the weight of the fly, but minus the weight of the equal bulk of air displaced by it. With regard to the cylinder and bullet problem, my own idea was that, as the bullet is travelling at a much higher rate of speed than the cylinder, the greater part of its energy would be converted on impact into heat, and the cylinder would swing past the point of impact, thus giving the converse of a heat engine where motion results from the absorption of heat; here motion resulting from the disengagement of heat. W. J. G. F.

A RACE WITH THE SUN.

[42786.]—In "E.M." of Sept. 1, 1899, an imaginary aërial machine is supposed to travel at 1,000 miles an hour. This is scarcely likely to be realised. But, suppose we have a locomotive capable of running 100 miles an hour, and that we lay down a railway along a parallel in north latitude about 84° 30′, or some 400 miles from the North Pole. A traveller, drawn along at 100 miles an hour on this circular line, which would be 2,400 miles long, would just keep pace with the Sun, if the train runs from E. to W., and the season is an Equinox. Going W. to E., the days and nights would be shortened to six hours each.

In a higher latitude, at the same speed, and going from E. to W., the traveller would gain on the Sun, which would slowly move from W. to E., set in the E., and rise later on in the W. In a latitude lower than 84° 30′ the days and nights would be lengthened; but the Sun would rise and set in the usual direction.

In a paper on the moon, published some time ago, I wrote as follows:—So slowly does the moon rotate that a brisk walker starting at noon, in lunar latitude 66° N., and walking along that parallel from E. to W., could keep the sun always in the south, and thus enjoy perpetual noon.

If, by cycling, he increased his pace, the sun would appear to back in the heavens from W. to E. A train, starting at noon, and going W., at 21 miles an hour, along the same parallel, would so gain upon the sun that, forty hours later, it would appear to set in the E.

President Leeds Astronomical Society.

Leeds, Sept. 1.

MICRATOMIC ETHER.

[42787.]—The remarks of "Lucretian" (letter 42770) are certainly worthy of consideration, giving rise as they do to instructive thoughts; but he will, I am sure, pardon me if I say that in places he seems to have become involved in a multitude of words, and thus fallen into error. As far as one

can see, the purpose of his letter is to show—(1) That the ether is composed of discrete particles (which he terms "micratoms") animated with great velocities. (2) That the atoms of elements are themselves composed of these micratoms grouped or arranged (I presume) in different ways in the different elements. (3) That radiant energy causes these micratoms to vibrate, and that these vibrations are communicated from one micratom to another by means of collisions. While leaving this third consideration to others more competent than myself to answer, and confining myself to the statement that I do not think such an hypothesis capable of satisfactorily accounting for the phenomena observed in the propagation of light, I should like to offer a few remarks on the first two considerations.

The medium which we call ether, which is supposed to permeate all bodies and to fill space, whatever its real nature may be, is certainly not *matter*.

In the past, different kinds of ether were postulated and endowed with various properties pertaining to material substances to meet the requirements of different hypotheses, and to explain various phenomena. This unscientific method has since given place to the more rational one of seeking to learn the true nature and properties of the ether from a study of the various phenomena in which it may be involved; and, at the present time, we are just beginning to be able to form faint but definite ideas as to its existence and true properties.

Let me reiterate that the ether is certainly not matter, and possesses none of the properties which we find associated with matter. This being the case, it is evident how very unscientific it is to credit the ether with any particular structure, and then to try and deduce from this assumption the courses which certain natural phenomena should take.

The very fact that radiant energy travels with such immense velocity, though undoubtedly propagated by means of transverse vibrations; the very fact that when we attempt to deduce the course of certain phenomena from preconceived and hypothetical notions as to the nature of ether, we are at once confronted with insurmountable difficulties;—these, and many more like them, all tend to confirm the above conclusion.

I do not mean that in investigating the properties of the ether, we ought to confine ourselves rigorously to the inductive method. The scientific use of the imagination is always fruitful; but if we allow our imagination to run away with us, we always fall into error. With regard to the second consideration, though in the past chemical compounds have been mistaken for elements, such a mistake would seem impossible now. If the elements are really non-elementary they must all be compounds of the same order, *totally* distinct from ordinary chemical compounds. There can not be the least doubt that there is a broad line of demarcation between ordinary chemical compounds and the elements. Nevertheless, there is a great deal to be said for the view that each element is *not* composed of a certain kind of matter totally distinct from the matter of which every other element is composed.

But whether, even if this view is correct, we shall ever be able to decompose the elements into this primordial form of matter is quite another question. For many reasons I am inclined to think not. There are several other points I should have liked to touch on, but I have already occupied too much space. I may do so (with the Editor's permission) in the future. In conclusion, I should like to say that if I, in my turn, have fallen into error, I shall be only too glad to have it pointed out. The real object of these discussions is not to support one's own opinion, but to arrive at the truth.

Trin. Coll. Oxon. J. M. W.

MICRATOMIC ETHER.

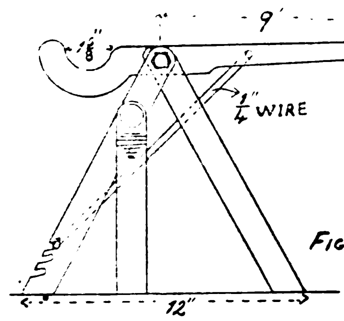
[42788.]—IN connection with "Lucretian's" letter in last week's "E. M.," would some reader kindly inform me whether any, and what, attempts have been made to "polarise" sound? If this can be done, then "Lucretian's" hypothesis will be much strengthened. I like his theory, because by it "gravitation" can be explained so simply, as also that other force known as "chemical union."

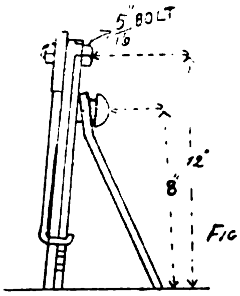
I might add that the polarisation of sound should, it seems to me, be expected just as much as that of light and heat. I will further explain, if so desired.

R. A. Kennedy.

LIFTING JACK.

[42789.]—IN view of the interest being taken by numerous readers of "Ours" in the motor tricycle, I venture to send a sketch of one of a pair of lifting jacks which I made a few weeks ago to lift the driving wheels of a tricycle, so that it could be run in the shop for testing, &c. These jacks are light, and can be folded up nearly flat, while the fact that a pair of them carried the motor and its 10-stone rider speaks for their efficiency. The legs and handle are made from 1¼in. iron, the handle being bent hot, and the edges rounded at the tapered end. Note on one of the legs the little lip





turned up to prevent the legs spreading too far. The rivet which holds the short leg is ⅜in., the hole in the leg being made a very sloppy fit to allow the leg to fold down flat. The piece of ¼in. wire shown clearly in Fig. 1 should be mild steel, as it has a good deal of strain on it. Where it enters the handle it should fit loosely and have the end burred over, so that it can move easily but not fall out. In Fig. 2 is seen the method of turning up the other end to engage in the slots in the leg. I have given sizes as near as I can recollect them, but a little variation will not matter. When the handles are horizontal, the cycle wheels should be about 2in. off the ground. The jacks should be placed as near the wheels as possible, and the handles should point away from the steering wheel of the tricycle. Notice that the jacks are not exactly vertical; if they were, they would fall over to one side too easily.

"Regent's Park" (reply 96403) gives a few supposed cures for burnt steel. Has that gentleman ever tried any of those mixtures? If so, with what success? I am not asking out of idle curiosity, for successful treatment will be worth many shillings to me, and also, I presume, to many other readers who use and work steel. Right here would I warn fellow-readers who burn the ends of their lathe-tools or other steel goods, to cut them off and remake or throw them on the scrap, and not to waste time, money, and patience in making such "mucks" as given by "Regent's Park."

Ernest W. Fraser.

MOTOR CYCLES.

[42790.]—ALTHOUGH I had not intended to enter this correspondence, I cannot but think that my experience with motor bicycles would interest "F. R. D." and others who have that burning desire to fit a motor to an ordinary bicycle. I was once so afflicted, and a cycle-making friend and I set to work to make a frame, to which we fitted a 60mm. De Dion motor. We fixed the motor behind the bottom bracket, leaving room between the bracket and the tire of the back wheel to take it in. The motor drove the back wheel by means of a chain gearing into a sprocket-wheel fixed on the back-wheel axle, on the opposite side to the ordinary hub, which contained a free-wheel clutch. The pedals were geared to 60; the motor ten revs. to one of the back wheel.

But all the flaws of the machine became apparent at the trial trip. To begin with, mounting was difficult; then there was awful work for a minute or two until the motor started, which it did with a jerk which nearly sent you over the handle-bar. On a level road the machine would run better, but the slightest unevenness sent the machine bouncing up and down in a most erratic manner. Sideslip was most evident, and after two falls I always led the machine through moisture or thick dust. To turn the spark off when going fast was like putting on a powerful rim brake. To stop without opening the compression cock was a most exciting experiment, generally resulting in a roll in the road. Needless to say, I soon gave it up and took to a De Dion trike, with which I have no fault to find. I believe when you ride an ordinary bicycle you instinctively apply the power when it is wanted; but the motor goes pounding on all the time.

H. Bevan Swift.

[42791.]—I WAS amused at the description of cross-gudgeon pin in piston of Dion motor getting tuneful. I think fault must lie with user, as surely makers would have found a remedy if trouble was serious, seeing they have orders for about 40,000 on hand at present. The trouble is not with the engine being vertical, this being far and away the best position to adopt, but in ignorance of user not trying to find cause of trouble. The chief difficulty to guard against, I can assure the writer, is to avoid getting too much oil, to prevent which a plate is cast right across crank chamber, with a slot only just large enough for rod to work through. The flywheels running in oil at 2,000 revs. per min. drive the oil up with incredible force right to top of piston. The connecting-rod at top end is, or should be, provided with an oil-hole ⅛in. diam., largely countersunk; in addition, the top bush has a groove from end to end 1/16in. diam.—this is on top side, pressure being on under side of pin. If oil fails to get here, probability is user of tricycle perhaps oils his cylinder with a locomotive squirt-can before starting on a long ride, and this with an oil quite *unsuited* for the purpose. The oil, which must be finest gas-engine oil obtainable (which, up to present, I have found none better than Price's), requires to be put in every 15 to 20 miles, and care must be taken to see aluminium case does not leak, sometimes caused by repairer throwing case on workbench studded with nails. In no case put more than two tablespoonfuls of oil at one *time!* Otherwise, extra oil is simply wasted in exhaust, and it tends to carbonise up on top of piston and round valves; then, as writer puts it, it smells to those on foot worse than to rider, causing a general impression it is usual thing with motors to fly along groaning and belching forth suffocating fumes.

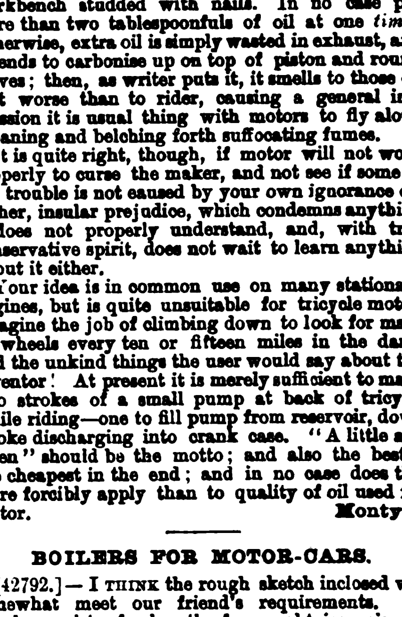
It is quite right, though, if motor will not work properly to curse the maker, and not see if some of the trouble is not caused by your own ignorance or, rather, insular prejudice, which condemns anything it does not properly understand, and, with true conservative spirit, does not wait to learn anything about it either.

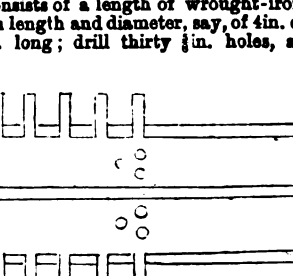
Your idea is in common use on many stationary engines, but is quite unsuitable for tricycle motor. Imagine the job of climbing down to look for mark on wheels every ten or fifteen miles in the dark, and the unkind things the user would say about the inventor! At present it is merely sufficient to make two strokes of a small pump at back of tricycle while riding—one to fill pump from reservoir, down stroke discharging into crank case. "A little and often" should be the motto; and also the best is the cheapest in the end; and in no case does this more forcibly apply than to quality of oil used for motor.

Monty.

BOILERS FOR MOTOR-CARS.

[42792.]—I THINK the rough sketch inclosed will somewhat meet our friend's requirements. It simply consists of a length of wrought-iron pipe of any given length and diameter, say, of 4in. diameter, and 18in. long; drill thirty ⅜in. holes, as shown





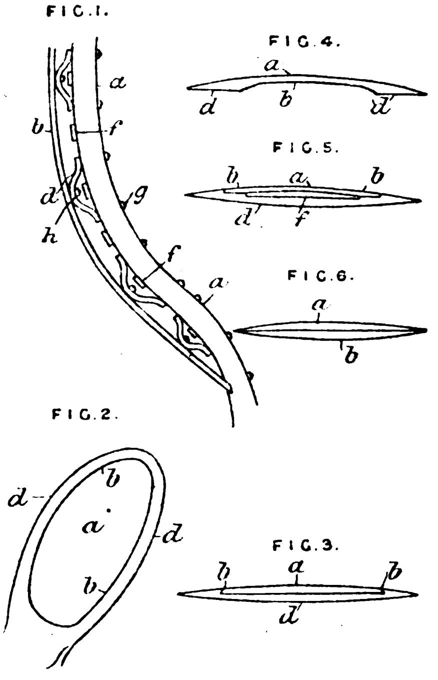
in sketch, and tap with fine gas thread. Then cut off thirty pieces of ⅜in. brass tube; one end of each must be stopped up by brazing a disc of brass, which will be best done "after cutting out the discs with a punch," with silver solder, made by melting two parts of silver with one part brass, then screw the other end to correspond with the holes in the iron pipe before mentioned. Then make two plates to act as covers, then the ¼in. bolt to complete the job. Make joints with asbestos paper, take the steam from the upper plate. Now the fire is of the oil type. By using this you can most easily control the make of steam when stopping, this being most essential, according to the Act. I should mention that the boiler should be placed in a fireclay

cylinder, such as are found in any ironmonger's shop, in the form of slow-combustion stoves, so that by increasing the number of tubes and length of main body, any amount of steam may be obtained, and steam may be got up to 50lb. in eight minutes. All steam must be condensed, which I have successfully done by carrying the exhaust pipe several times round the frame of the carriage, ending in the water-tank under the seat, so that very little water is necessary. R. Allison.

IMPROVEMENTS IN SHIPS' PROPELLERS.

[42793.]—On a former occasion I had the privilege of submitting in the columns of your paper, for the critical examination and approval of your scientific readers, certain improvements in chain-gearing, and I am glad to believe that my doing so was largely instrumental in securing the appreciation of the novel principles involved, and adding to the gratifying measure of success my Resilient chains have already attained. I again seek your hospitality in order to lay before your readers details of certain radical improvements in the construction of ships' propellers recently invented and patented by me, the importance of which becomes sufficiently manifest by the statement (the truth of which I shall demonstrate) that they are calculated to materially increase the speed attainable by ships, to lessen the requisite consumption of fuel for any given speed, and to reduce the tendency of the machinery to break down. To those who attribute the abnormal increase of driving-force now requisite for the attaining of a comparatively insignificant addition to the existing high speed of vessels to the increased frictional and other resistance of the displaced water, my first proposition will appear to be an untenable one; but experience and a careful examination into the various dynamical circumstances involved have convinced me that such a theory is not the true one, and that it is inconsistent with the rules governing the development of force and resistance;—hence it follows that the explanation must be sought elsewhere, and I am glad to believe that I have succeeded in finding it and in providing an effective remedy. My view is that such apparent resistance is, to a very large extent, due to the leakage of energy and destruction of the density of the water caused by the "shock" of the impact of the propeller blades on the water, which, by concentrating an abnormal application of force into an atom of time, causes the faults above referred to without increasing the momentum transferred to the water, or the vessel's speed.

The following facts all go to demonstrate the truth of my contention, and as they have hitherto been practically ignored in calculating the efficiency of propellers, I give them in some detail. When even a moderate rate of speed is being attained, the pressure of the "faces" of the propeller blades on the water is greatly in excess of that of the height of the superimposed column of water plus atmospheric pressure; hence the displacement caused by each blade must, under such circumstances, inevitably leave a vacuum at its reverse side, which vacuum must, to a large extent, in consequence of the "slipping" of the blades, be passed through by the succeeding blade before it finally strikes the more solid mass of water beyond. Again, the inherent imperfections of all crank-driven machinery cause perpetual variations in the velocity of the shaft, and consequently of the propeller, and *pro tanto* relative momentary increases in the resistance of the water, which also have the injurious dynamical faults of "impact." Further, the resistance offered by the water acted upon constantly varies, not alone with the perpetual variations in the condition, height, movement, and mass of such water, but even that offered under most favourable circumstances to an ascending blade is materially less than that against which a descending blade works. Every one of those circumstances goes to cause an intermittent action of the driving pressure, and either a relative or an actual succession of "impacts." They thus set up an increased friction and recurrent concentrations of the driving force, which thus wastes itself in lessening the density and consequent effectiveness of the water as a propelling medium, in vibrating the hull of the vessel, and in causing that "shock" and consequent reaction which is the direct offspring of a misapplied propelling force, and a fruitful source of the snapping of the blades and of breaking down of the machinery—in a word, it means a gigantic leakage of power. Those faults become intensified with any increase to a high velocity, and, to my mind, demonstrate the truth of my contention, that the difficulties then encountered arise mainly from shock, and that they may better be met by a conservation of the existing driving energy than by abnormally increase of horse-power. Apropos of this, it is worthy of notice that better results are obtained when their flexible propeller blades are used than with those devoid of such flexibility; but such flexible blades have serious faults which I shall later on refer to. One other consideration I should like to lay before your readers before proceeding to explain my improvements. The laws governing the waste of energy incidental to the impact of bodies are epitomised by "Newton's experimental law," which demonstrates that such loss is in proportion to the absence of elasticity in the masses colliding, and he has shown that where perfect elasticity exists, all loss by impact ceases—that is, where such elasticity is accompanied by the proper "coefficient of restitution." Hence it follows that *elasticity on propellers must prove of advantage.* In such conditions it is the radical and only cure for "shock," and when it is recollected what an enormous waste of force is now occasioned by such "shock," in the propulsion of vessels by propellers, some estimate of the advantages to be obtained may be arrived at. In the case in question, the measurement of the proper coefficient of restitution may be taken to mean a resilient force approximating to that of the normal *resistance* offered by the vessel when being propelled at average speed, apart from that occasioned by "shock," as then any lesser force would be unable to give back in propelling the vessel the full pressure-force absorbed in causing elastic compression, and consequently a waste of energy would ensue. This is one of the faults inherent in the thin, weak, and flexible propeller blades, and in endeavouring to overcome the inordinate yielding of such blades, that arose when they were shaped in accordance with the normal "pitch," another serious fault became inevitable, because by increasing the twist of the blades in order to increase their resisting force, their true driving pitch had to be abandoned, and their working displacement largely increased, causing thereby increased vacuum at reversed sides, increased friction, and a decrease in the momentum



communicated to the water. This shaping is much in evidence in the propellers used in torpedo craft and the like, and the vacuum thereby occasioned by causing increased "churning," largely explains the absence of vibration, which is principally due to the reduction in the density of the water acted upon, in addition to which the "rebound" of such blades increases the subsequent velocity of impact and "shock." I would also direct attention to the important difference between such elasticity of flexure of thin blades and that of direct compression provided by my improvement—viz., the elastic resistance in the former case varies from zero at the base of the blades to a wholly excessive amount of yielding at their extremities, and thus the greatest force is met by least resistance. Whereas, by the latter, an even resiliency may be provided throughout, or its force may be increased at the extremities. My invention shortly consists in so constructing the propeller blades as to combine requisite strength with sufficient elasticity on their faces, and a *full and lasting resilient* force. Fig. 2, of drawings annexed to my patent specification, shows the faces of a blade hollowed at the centre at *a*, *d d* being the surrounding flanges. Fig. 3 shows a sectional view of same, *d* being the hollowed blade, and *a* being any suitable elastic substance fixed in such hollow. Fig. 4 shows another form in section, *a* being the face and *b* the reverse side. In this case the edges at *d d* have increased substance, so that they may offer the necessary resistance whilst the central thin portion, *a*, yields under the force of undue pressure. If desired, the hollow at rear may be covered so as to provide for reversing. Fig. 5 shows another form, in which *a* is a steel plate fixed over the propeller blade *d*. This may be securely attached, as shown, by riveting or otherwise, and the space between plate and blade may be filled in with any suitable elastic substance. By those means the required elasticity may be combined with a resisting force in the blades which will enable them to be constructed with the most advantageous "pitch" for driving purposes, and such elasticity may have a perfect coefficient of restitution at *all parts*, unlike that of flexible blades, in which the greatest pressure which takes place at their outer extremities is met by the weakest resisting force or by a distortion of the "pitch," which alike destroys their driving efficiency and increases friction. The increased sectional thickness occasioned by the use of my invention will add little, if anything, to the friction of such blades, as such thicknesses being substantially at the centre of the reverse sides, it will be well within the lines of the deplacement caused by the oblique action of the blades on the water. The increased weight, affording as it will an increased momentum force, will prove advantageous, as it will reduce tendency of the blades to "react" after impact with the water, and thus enable them to impart a greater momentum to the water. Such decreased reaction will also much lessen the jarring on the machinery, and consequent tendency to break down. As to the regulation of the elasticity and resilient force, Hooke's law shows that, under such conditions of elastic compression, the amount of the elastic yielding is in direct ratio to the force of the pressure applied. To this dictum, which ignored the element of time, may be added the factor that such yielding under any given applied force is considerably greater than is generally imagined, inasmuch as it increases in the case of impact pressure with the square of the velocity of such impact. This latter fact I have ascertained from experiment, and as it is, so far as I am aware, contrary to the hitherto accepted theory of viscosity, I would commend its consideration to scientific readers. It would also go to explain the remarkable virtues of even an apparently insignificant elasticity in many dynamical problems, as for instance, that of the increased penetration and improved wearing powers obtained by its introduction into the construction of heavy guns. As to the amount of yielding requisite, some misapprehension appears to exist. The function of elastic yielding in such cases being to spread the application of a sudden and abnormal force over an increased space of time and doing of work, it follows that in the case of any powerful and rapid dynamical action, a slight amount of yielding supplemented by a powerful resilient force is sufficient and even preferable to any greater yielding, especially when time and distance are of moment. As regards the maintenance of the face elasticity, it must be remembered that, so long as the "limit of elasticity" is not exceeded, the resiliency lasts indefinitely, and that such "limit" will not even be approached except when the greatest pressure requisite for attaining the highest speed is being applied; whereas in flexible blades such "limit" is constantly and inevitably exceeded, the result being "tiring" of metal and snapping of blade. In conclusion, my conviction is that by the use of my invention a large proportion of the force now wasted in vibrating the vessel and in "churning" the water may be diverted into procuring an acceleration of the speed, that a more constant application of the driving pressures may be obtained, and my calculations all go to show that an increased speed of from 15 to 20 per cent., and possibly even more in the case of shallow craft may be attained.

Fig. 1 is a sectional view of part of a yacht's frame to which the invention is applied, *a* being one of the timbers having my outer frame or timber *b* attached to it by means of the intervening "steel springs" *d*, each being secured as shown at *g h*, or otherwise suitably fastened. *f f* show sectional views of suitable "stringers," preferably of steel, which I fasten longitudinally outside the inner frame so as to securely brace it up. The outer frame *b* may be made of steel, elm, or other suitable material, and of the required substance, the vessel's planking or sheathing being fastened to it by bolting, riveting, or otherwise. In place of the springs as shown, any other suitable contrivance or yielding substance may be used. I would place a sufficient number of suitable light ribs between such spring timbers so as to secure the planking so attached from leaking. I would graduate the elasticity so procured so as to assimilate its extremities to that of the planking with which it ultimately comes in contact, and when applying my invention to small craft I may support such outer sheathing with suitable pads of inflatable rubber, and thereby enable its elasticity to be readily regulated to suit all weathers, in which case I would have a suitable inner ceiling. The shape and position of "timbers" so treated must be altered so as to enable the outer frame to receive and support the planking in the required lines. This invention may also, with suitable modifications, be applied to the outside of the ordinary sheathing of the bows of vessels, and it should be found beneficial when thus applied to armoured ships; it may

also be applied for the purpose of reducing the "impact" of shell of such armour, in which case I would use an inner plating of suitable soft and elastic metal. Fig. 2 shows the face of a propeller blade made in accordance with my invention; *a* being the hollow face, *b b* the edges of same (slightly hollowed as shown at *b b*) Fig. 3, and *d*, *d* solid edges of the blade.

Fig. 3 shows a sectional view of a propeller blade made in accordance with my invention, *d* being the blade or casting as shown in Fig. 2 and, *a* a facing of soft spring steel or other suitable material the same being securely fastened by welding, brazing, riveting, pressing or otherwise. Fig. 4 is a sectional view of another propeller blade made in accordance with this invention; in this case the required elasticity is procured by hollowing the reverse side *b*, the substance of the surrounding edges being increased as shown at *d d*, for the purpose of maintaining the required strength in such blades, the central portion being sufficiently thin to allow of its "springing" sufficiently when the driving pressure is applied at the face *a*. This form I would preferably forge, or roll from suitable steel or bronze. Fig. 5 shows a sectional view of another form of my improved propeller blade, *a* being the solid blade with hollowed face, such hollow being covered by the plate *e*, made of elastic metal and securely fastened to the surrounding flange *b b*, as already described, leaving a hollow space at *f*, which may if desired be filled in with any suitable elastic substance. Fig. 6 is a sectional view of another propeller blade, the face *a* being composed of softer metal than the reverse side, *b*; this may be effected by joining two different sections of metal, or in a less advantageous form it may be got by having the face *a* tempered more softly than what is required for the reverse side *b*—or I may "shroud" the blades with soft steel. **P. M. Staunton.**

Dalmeny, Howth, Dublin.

THE DELUGE—THE MOSAICAL DAY.

[42794.]—A BELATED letter such as that of Mr. Kelly (42761) provokes questions similar to those which have appeared in a certain daily of late. Is it worth while? Is it good enough?

Certain facts have been reproduced in these columns within the last few weeks which do not support the universality of the Deluge, and the arguments thereon have not been invalidated. Until Mr. Kelly is in a position to controvert them, it would surely be best to refrain from displaying such utter ignorance of geology and zoology as his letter evinces. There is no need to proclaim oneself blissfully unaware that the moose, even at the beginning of the Christian era, lived south of the Baltic, and still inhabits Northern Asia and Europe, that elephants roamed over Europe in former days, and so on. I daresay he would object to my advancing the extermination of the wolves in the British Isles about A.D. 1710, reindeers in the twelfth, bear about the tenth, beavers in the thirteenth, and wild boars in the seventeenth centuries as proofs of universal deluge at these periods. But *cui bono?* Facts don't trouble the Diluvialist. He manufactures them if necessary. Although it was as chronologically impossible for either Newton or Halley to be acquainted with the bulk of facts now available to the disproof of the Flood as it was for them to be conversant with spectroscopic astronomy, yet the Diluvialist esteems their opinions on the subject convincing, I can assure Mr. Kelly that to maintain the literal veracity of the Biblical Flood narrative serves far more to promote scepticism and disbelief than the frank avowal that it is a poetical myth based on a disastrous local inundation. If he likes a definite up-to-date conclusion of "modern research," here is one from Bonney's admirable "Story of Our Planet" (ed. 1893), p. 530: "Certainly there is not, even from the earliest epoch, the slightest evidence of any general catastrophic destruction of life and repeopling of the globe."

If Mr. Monck (letter 42724) cares to refer to "Haydn" (ed. 1895) he will find sixteen of the dates which have been assigned to the Flood tabulated therein.

One doubts whether it would serve any useful purpose to discuss letter 42762. Mr. Hardy ought certainly to tell us which Assyriologist has proved the Chaldeans called their years seconds, and anticipated Hipparchus in discovering the precession of the equinoxes. It does not help matters to say all primitive people count by fives and tens, for some Australian aborigines do not get beyond ones and twos. It is not necessary to remark that any lengthening of the day in Chapter I. of Genesis raises questions about the age of the patriarchs in Chapter V., or that for Adam and Eve to live throughout the seventh day and attain at least a respectable age of 86,400 years does not seem to rationalise the undertaking. For neither competent geologists nor physicists will dream of accepting even seven periods of such duration as sufficient time for the evolution of the whole universe. One vastly prefers to regard the account of the Creation as poetical as Homer's Trojan epic, for instance, and not a *verbatim et literatim* report of actual proceedings. **J. Dormer.**

THE COMET AND THE DELUGE.

[42795.]—I NEED not discuss the views of Newton, Halley, or Whiston about comets. If Cometary Astronomy has made no progress during the last two centuries it differs widely from all other branches of the science.

I fail to see any more reason for believing that there was a great comet (to say nothing of the water comet) in the year B.C. 3102 than in the year B.C. 2356, or any other very early date that Mr. Garbett chooses to fix on. I have more than once indulged in speculations in astronomy, and have been pitched into for so doing. But speculators ought to have some foundation in observed or recorded facts, and for the theory of a universal deluge in B.C. 3102 caused by a comet composed of water, I think it would be desirable to give something like evidence that there was a deluge in that year, that there was a comet in that year, and that comets are sometimes composed of water—though, granting all three, it would be difficult enough to reconcile the theory in question with the narrative in the Book of Genesis. **W. H. S. Monck.**

THE DELUGE.

[42796.]—MR. LEONARD KELLY writes that "the very simplicity of the narrative of the Deluge is the most conclusive proof that Moses wrote just as he was inspired to write." I should advise Mr. Kelly to study a little more his Bible, possibly in the Hebraic original, and then say why the narrative in this case runs sometimes under the name of Elohim and sometimes under the name of Jehovah, and just so that if all the paragraphs of the one and the other name are put together, there are *two complete* stories of the Deluge, both the same as to the substance, but differing in the details (the two and the seven pairs, &c.) I expect he will find out easily that "simplicity" has to be applied to something or somebody else.

How can Mr. Kelly say that the flood was caused by the water suspended in the atmosphere being suddenly condensed, when he says just at the beginning of his demonstration that this water would make a stratum of only 20ft. depth? Twenty feet of water that reaches up the "high mountains"? Would it not be better in any case to stick to the theory of the "watery" comet, no matter how watery? Mr. Kelly says that shells of oysters have been found on the tops of all the high mountains. Does he think the time the Deluge is said to have lasted was sufficiently long for depositing sometimes strata of mètres and mètres of shells?

Mr. Kelly marvels at the Ark having landed on Mount Ararat, and takes it as a proof of the finger of God. I should, however, like him first to prove that there was actually the Biblical deluge, as described, and Noah's Ark—as I do not see that the "elementary facts of experience" he mentions prove that; and also let him kindly explain, if it is an "elementary fact of experience," that of the aqueous vapour all over the world condensing suddenly, and the 20ft. of water that submerge 8,000ft. mountains.

Poor religion! At first it made Galileo hold his tongue by force, then it mocked Darwin, and declared his theory ridiculous and absurd, and now it comes humbly to the very same science it did all in its power to crush down, and feigns to exalt her, whereas it only steals her crumblings for support.

Milano, via Zeccavecchia. **Libero Gorio.**

[42797.]—WITHOUT replying to the main point in "Little Bookham's" letter (42721), it seems very clear that the return of the shadow on Ahaz's dial was *not* caused by any magnetic influence, nor yet was it an atmospheric effect, as implied in Mr. Garbett's letter (42774). The return can be explained by the occurrence of a partial solar eclipse, which would hide the upper portion of the sun's disc.

Hezekiah's illness is fixed by Demetrius as having occurred about the time of such an eclipse which happened on Jan. 11, 689 B.C., at 11.30 a.m. The only difficulty in the explanation is that the form of the dial in question is unknown; but if it took the form of the Greek heliotropian (an arrangement of steps rising towards the sun when on the meridian, so that the shadow of the gnomon fixed on the top would just fall on the bottom step when the sun was at its lowest altitude), the partial total eclipse would explain the return of the shadow, in that the eclipse of the upper portion of the sun's disc would have the same effect as lowering of the sun's altitude, and would cause a lengthening of the shadow, throwing it back a certain number of steps—as to how many it would return depends upon the total number of steps in the heliotropian. The effect of the actual eclipse would be to throw the shadow back one-twelfth of the total length. If the total were 120 steps, then the steps or degrees which the shadow returned would, of course, be ten.

That Ahaz's dial did take the form of the heliotropian is suggested by the profane writer Glycas: —"They say that Ahaz, by some contrivance, had erected in his palace certain steps, which showed the hours of the day, and also measured the course of the sun."

I would recommend "Little Bookham" and others to obtain G. F. Chambers's, F.R.A.S., little book, "The Story of Eclipses" (from which I have borrowed), recently published by Geo. Newnes, Ltd., as one of the "Library of Useful Stories," in which they will find this subject dealt with in detail with diagrams in illustration.

To those interested in the Solar Eclipse of May next, I would also recommend that book. There is a very interesting diagram of the planets and principal stars which will be visible during the eclipse which will no doubt prove useful.

It is possible that the record of the sun standing still in Gibeon, recorded in the 10th chapter of Joshua can receive as satisfactory an explanation as Mr. Chambers gives of the returning shadow.

Huddersfield, Sept. 4. **Wilmay.**

[42798.]—LEONARD KELLY seems to repeat (in p. 66) what Bible notes used to say early in this century. But nobody can "examine the highest eminences on earth," because nobody can climb to them, and it is even doubtful whether anybody transported thither could live ten minutes. The cold would be too extreme, and the air not a third as dense as what we commonly breathe. The mountains known to contain "shells and skeletons of sea fish" are far from the highest; and, moreover, indicate no flood of a few days, but immersion in the sea for ages. Some mountains of only moderate height seem never to have been under sea, as those of Scotland and of Auvergne in France.

The account in Genesis (not by Moses, but probably much older) says, "the waters prevailed 15 cubits when the mountains were covered." That must have been Noah's belief, meaning that he knew the draught of his Ark to be 15 cubits when it grounded. As he and his family never saw a higher hill than Ararat, it means that this was 15 cubits under water when he grounded. It then rose till becoming now some 10,000 cubits over sea-level. The account nowise implies that other mountains, unknown to him, were under the sea. They were simply deluged with rain that swept everything off.

It is a gross error to say the atmosphere contains enough "to cover the whole globe to the depth of 20ft." It never contains enough to cover it with half a foot. The sea contains enough to yield more than a mile, if the globe were all level. But it has an old cliff line, 600ft. below its present level. That is what I fancy to have been the pre-Noachian coast. The quantity of rain to raise the sea to its present level may have been between 400ft. and 450. Halley's and Newton's theory affords abundant water for that, but I never heard of any other theory affording a tenth enough.

What is now wanted, in geology above all things, is clear particulars of the timbers Nouri (or Honri or whatever his name is) saw on Mount Masis;—those that, according to Missionary Wilson, "*deceived* him." **E. L. Garbett.**

THE MOSAICAL DAY.

[42799.]—TAKING the day as a period of 43,200 years, or, rather, 86,400 years—I don't see why Mr. Hardy (p. 66) could not have doubled it again, it would have brought him a bit nearer—and multiply by six—six days being the period given in the only (rather doubtful) authentic record in existence; this gives us a period of 518,400 years as the time taken by the Creation. Now it is manifest, or should be, to any intelligent person, that 518,400 years is but as a minute is to a day in the time required for the evolution scheme. I do not think the Chaldeans made their days half long enough. **Silverplume.**

AHAZ'S DIAL.

[42800.]—MANY thanks to Mr. Garbett (letter 42774) for his kind reply; but I do not think that atmospheric effects caused the return of the shadow on Ahaz's dial. I think that would not explain the standing still of the sun and moon. See Joshua x. 13, "So the sun stood still in the midst of heaven, and hasted not to go down about a whole day." I think this points to other causes than atmospheric effect. I should much like to see my question answered: What would happen if the South magnetic Pole was moved a thousand miles nearer the North Pole? as I think it has a great bearing on the subject. Now, would the earth revolve in a different manner than it does now, and what would be the probable effect on springs of fresh water? **Little Bookham.**

THE FUTURE OF AERIAL LOCOMOTION.

[42801.]—WILL you kindly permit me to point out, in reply to letter 42756, that I have not claimed in these columns the originality of Jules Verne's creation, but have aimed at demonstrating how the system of the screw for both elevation and pro-

pulsion with suitable concave surfaces is the most practical to imitate the principle of nature? What I certainly should have said is, "that the design, although taking it as an illustration, is far more practical in technicalities and concentration of scientific facts than Jules Verne's imaginary one." For this I have shown how absolutely indispensable concave surfaces are to retard a sudden fall when, for instance, the machinery might break down; how the ram in front, if movable, would act as a rudder for steering right or left; how the fan-shaped horizontal tail in the rear would assist an inclination upward or downward after impetus; how the twin-propellers are more effective to throw the air behind the blades than a front one, how the eight blades on a vertical shaft, being of larger diameter, would be proportionately of higher efficiency, how modern light oil-engines are more suitable than the imaginary ideal accumulators mentioned, &c.

Thanks to Mr. Challis for his warm remarks respecting same. My own original ideas, it may interest him to know, are on precisely the same principle (the screw); but the hull of the flying craft is cylindrical, with a sharp bow to minimise air resistance, with concave surfaces, horizontal rudder, elevating and propelling screws, &c. In short, I assure him my design contains *practical* lines over other systems, that I can claim still his cordial verdict, in that "I have broken all records in publishing far and away the best flying-machine as yet devised." I sincerely wish him, therefore, every success with his own ideas.

E. Wilson.

[42802.]—MR. L. SENECAL's letter (42702, p. 16), in commenting on Mr. Challis's limited ways, &c., gives us an important suggestion, "from a few yards to several miles long," giving greater range of safety for balancing. There cannot be any doubt that the failures of all flying-machines, past and present, are due mostly to the want of stability. This is simply because the machines were too small, and consequently the fractions of time too short for any efficient control of the motions of these machines. But the results would be very different with aërial machines of very large dimensions, as the times of the oscillations would increase and follow directly with the linear dimensions, as is the case with the large sea-vessels which give ample time for controlling (when necessary) their motions, which become almost impossible in the case of the model placed in similar conditions. These large machines, when once launched, should never touch ground again, but be perpetually sailing the atmosphere like the albatross, frigate bird, &c.; they probably could be constructed on aërial docks and launched on the gale, and then proceeded with by analogous methods and processes to sea-going vessels, which service is carried on by smaller craft; similar means could be adopted for aërial machines. Aëronauts tell us that the greatest danger of ballooning lies in leaving the ground, but specially in landing: the same will apply without exception to all flying and aërial machines. Keeping this in mind, it follows that small machines (aërial) doing the land service must be structurally and materially stronger, more powerful as regards motive power for controlling the weight of the whole machine, and consequently much heavier proportionately than the large sailing machines, while the steering and stability may remain the source of great trouble and danger. But with machines that would never come near land this state of things would be reversed, on account of the conditions surrounding the floating structures comparatively speaking. The first machines could be launched either from a high cliff or mountain, or better *still*, from an Eiffel Tower fitted with counter-lever beam crane with rotary motion. These structures would also solve many unsolved problems, such as etheric telegraphy, telephony, light- and sound-waves propagation, &c. F. Willey.

[42803.]—IN my former letter (42652, p. 558, Aug. 4) it was intended to describe the flight of "certain small birds in rapid flight." I have seen a small bird beat its wings for a second or two and then fold the wings tight to its body while it moved on with the rapidity of a stone thrown from a sling. Not having seen anything like it described, nor an accurate account of it, I should like to know what birds fly in this manner. My friends say owls fly so in daylight. The speed of flying was very great, much over that of an express train, and the line of flight horizontal, a little above the tree-tops. The turkey and the vulture are both heavy birds, and I would be glad to know whether the large birds of prey fly as before described.

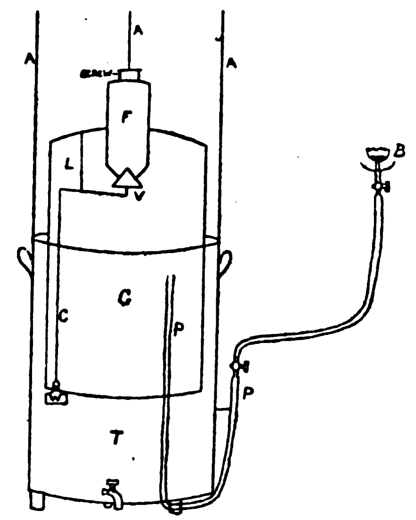
In regard to the limit of size in the figure-of-eight wing it depends on the nature of the materials. Mr. Senecal will no doubt be aware that the construction of a large flying model with indiarubber motors is a matter of difficulty, and this is because of the nature of the elastic material used. I have made a great many of these models in geometric sizes, and find that it is no use trying with too large a size. In consequence, it is supposed that the figure-of-eight wing, being elastic, will have a limit of size also, like the indiarubber motors. Kaufman's flying-machine described in Vol. VIII. p. 73 of the "E.M." broke its wings off short on trials, and, later, Welner's experimental rotary wing could not stand the strain on the materials when driven at full speed. J. Sutcliffe.

[42804.]—ANENT the discussion on flying-machines, I see that no notice is taken of what might be called the valve-action of the pinion feathers of the wings of birds during flight. A pinion feather has a broad and a narrow side. If this feather is waved up and down, the broader side offers more resistance to the air than the narrower one, and it tends to rotate on its axis or shaft. Again, if a wing is waved so as to imitate flight, the resistance to the up-stroke is very much less than to the down-stroke, as spaces open between the feathers by their broad sides screwing round, and allowing the air to pass freely through. In the down-stroke, the feathers act like valves, the broader sides closing up against their neighbours, the wings thus becoming airtight.

Now, could this principle not be applied to those machines in which the wings of birds are imitated by using materials such as thin wood and steel shafts, to imitate the broad and narrow sides of pinion feathers? G. Dickson.

ACETYLENE GAS GENERATOR.

[42805.]—I INCLOSE my idea of a reliable acetylene gas-generator, which I have worked for three months, and have had no trouble with it. I know that some of our readers would take interest in it by following the instructions. In the figure T is bottom tank that holds water; G is gasholder; F is



carbide-holder; V is valve; L, lever; C, chain; W, weight; P, outlet pipe to supply gas-burner B; iron rods A for guides for gasholder. The instructions are very simple, as it works automatically, as when the carbide-holder is full a portion of it falls into the water and gas is made intently; the gasholder rises, and the valve closes by the weight. Any one of our readers may call and see the same at work. H. Matthews.

122, Third-avenue, Queen's Park, W.

LEGAL REMEDY.

[42806.]—"A FELLOW of the Royal Astronomical Society" (letter 42712, p. 37) is no doubt right as to there being theoretically a legal remedy in the cases mentioned; but, practically, the remedy is worse than the disease. In each case some time elapsed before the purchaser became aware of the fraud practised upon him, and no doubt the dealer would have fought tooth and nail. In my own case, after only two days' purchase of an article which it was impossible the seller could have forgotten, I was met by a flat denial that the man who served me had ever seen me in his life, or had any memory of the sale. Fortunately, I had not any complaint to make, but he was consistent in his denial, even when he found that out. How would it have been in other cases? But I want to point out that although we have the most upright judges in the world, still law is a very costly thing *to a complainant*. The defendant often suffers, but *the complainant always is punished*. It was cheaper to put up with the first loss than to incur law expenses of greater amount, even if successful. I was advised by a solicitor in a case where a man obtained goods on credit when his books were already in the accountant's hands, that he was certainly in the grasp of the law, and I might get him three months, but it would cost me £50 in any case. I could fill the "E. M." with instances such as this, and worse. Suppose the purchaser of the £50 6in. had sued for damages, and recovered his money with costs, even then "costs" recovered are not costs as between solicitor and client, and £50 is a moderate estimate of their amount, which would leave him without either instrument or money, while there is the possibility he might have failed to get redress, and had to pay the dealer's costs in addition. This is a case again in which, before moving a step, it is best to consider and Hear Both Sides.

EFFECTS OF CHANGE OF TEMPERATURE.

[42807.]—ARE the textbooks wrong? I find in one the following regarding the effect of a change of temperature—viz.: "If the pressure remain constant an increase of temperature of 1° Centigrade produces in a given mass of air an expansion ·003665 of its volume." Consider the foregoing in the following manner—

Let V be the number of cubic feet in the original volume.

a be the increase ·003665 of 1c.ft. due to a rise of 1° Centigrade in temperature.

M be the new volume in cubic feet.

r denote the volume of 1c.ft. after the temperature has been raised 1°.

Then $r = 1 + a$, and Vr = the volume in cubic feet after a rise of one degree in temperature. Now raise the temperature another degree, and the volume will be Vrr or Vr^2. Raise it another degree and the volume will be $Vrrr$ or Vr^3, and so on. Thus $M = Vr^n$, where n is the number of degrees increase in temperature.

Should this solution of gas expansion be the correct one, a volume of gas will more than double itself if the temperature is increased 273° Centigrade, whilst lowering its temperature would never cause it entirely to cease to exist. Then what becomes of the imaginary absolute zero? William E. Tanton.

PRINCIPAL AND INTEREST.

[42808.]—MR. MONCK makes nonsense of my teaching at p. 67, by taking me to advise gratuitous lending, which is, like all charity, hateful and damnable to every capitalist.

"I hate him, for he is a Christian;
But more, for that, in low simplicity,
He lends out money gratis, and brings down
The rate of usance here with us in Venice."

Mr. Ruskin is easily attacked on this ground, because, in condemning the crime of borrowing or lending on interest, he begged people "to observe respecting ancient or modern denunciations of interest, that they are much beside the mark unless they are accompanied with some explanation of the manner in which borrowing and lending, when necessary, can be carried on without it." But he never observed that the Bible, the chief of the ancient denouncers of interest, did not begin denouncing it (in Exodus xxii.) till *after* describing, in Genesis xlvii., the hugest possible case of borrowing and lending without it. We cannot find any case of greater contrast between rich and poor than between Pharaoh and his people, when the famine had enabled Joseph to buy up all the seed, live-stock, and tools of Egypt, and finally to buy the people and their land. Pharaoh was then sole capitalist and landlord, and the people mere wagelings.

Never was such an occasion for capitalism on the hugest scale, and national debt *consols* at ever-so-much per cent. But Joseph taught them to lend and borrow by *partnership*. He took the labourers, one translation says, into cities, or, another says, "made them slaves." But the supreme point was that, if he made them Pharaoh's slaves, he made them Pharaoh's *partners*.

That was understood also throughout the middle ages—that if one contributed capital and another labour, they should agree on the rate of division of the earnings; the *whole* earnings, not the excess over certain wages or certain interest, but the whole earnings to be divided—in the Pharaoh's case, *four-fifths* to labour and *one-fifth* to him, the sole landlord and capitalist. The "uncertainty of rate of interest" has to be divided always between them. No such thing as a fixed "rate of interest" was ever allowed, because, as Lord Bacon predicted, where usury is allowed, it bringeth all the wealth of the state into too few hands, for as usurers trade on a certainty, but all other men on uncertainties, at the end *all* the money will be in the box."

In the New Testament, Mr. Monck quotes the parable of the Talents, but not that of the Pounds. Both contain the case of the idle and wicked servant, though the two parables give very different views of Divine justice. In neither of them is any interest taken, by the master or anyone else. Far from taking "what he has not sown, or gathering where he has not strawed," he does not resume his own principal. But the servants (who are not agents at all) are praised and rewarded proportionally to their industry in the Pounds case, where they

deserve unequally; but in the Talents, where all are equally deserving, they all fare alike. The pound of the idle servant is given to him who had ten pounds; but the bystanders expostulate, "Lord, he hath ten pounds." In the other parable, the talent of the idle servant is also given to him who hath ten talents; but there is no expostulation, and I fancy this particular has been copied from one parable into both. I deny that there is a "capitalist" or an "agent" in either. The profitless servant is called not only idle but *wicked*, because he falsely taxes the master with meaning to take other men's earnings, or, in short, to play capitalist. "Out of thine own mouth will I judge thee." Thou tookest thy master for a vile usurer—taking what he has not sown. Well, then, to avoid being fleeced by him, why not have put his money in a bank, or as the other parable says, to the "*table-holders*," or bankers; that so, on the rascally capitalist's coming, he might require not only "his own," but "usury" that was not his own, besides?

The notion that he approves of banking, or would have had the money banked, is absurd; for he could have banked it himself, instead of letting "an agent" do so. Bankers are merely regarded as an organised gang of thieves; but the difference between burying the money or banking it is that in one case the investor will share in their plunder, in the other case not. Whether there be more or less in the banks really makes no difference to them. They obtain all the usury that the nation's poverty can yield. This is then divided between investors proportionally to their investments.

For just two centuries, since they sanctioned national debt, we have only an idolatry for Anglicanism. Capital, or Ευπορία, teaches us what god to worship, and whoever dies a capitalist dies with the mark of Ευπορία in his right hand or forehead. E. L. Garbett.

LIQUID AIR.

[42809.]—Is liquid air the valuable article it was said to be? It was said that if you, with a steam-engine, produced 10c.ft. of air, you would never require a steam-engine again, because 3ft. of air used as power were enough to produce another 10ft. of liquid air. So that you could go on for ever without any other motive-power than the three-tenths of the air you liquefied applied to producing a further supply of 10ft. successively. Thus giving a constant supply of 7ft. to utilise for propelling machinery either on land or on a ship at sea? Will any of your readers who have actually produced liquid air give an honest reply to this question? G. A. H.

USEFUL AND SCIENTIFIC NOTES.

In 1898 there were 159 schools of science in existence, with 21,193 students. This is a considerable increase on the preceding year, when the number of the schools was 143, with 18,142 students. Schools of science in Scotland are not included in these figures.

The Imperial authorities have recently definitely resolved to extend the Central-Asian Railway to the town of Werny, and thence in a northerly direction. It now remains for the direction of this new line to be decided upon. A detachment of engineers has already left Tashkend for the purpose of making a preliminary survey. Two routes have been suggested: one would be across the Steppes to Orenburg, to the southwards of the Ural Mountains, and the other, viâ Semipalatinsk, to Barnaul and Krivoschtschekovo. The former route has very influential supporters in the persons of the cotton-growers of Tashkend and the manufacturers of Moscow, all of whom naturally desire to have the shortest possible means of transit for conveying this raw material to Moscow. A recent conference at Semipalatinsk clearly proved the route viâ that place and Barnaul will be the more advantageous. The authorities will allow the new line of railway to be built by private enterprise.

The *Bulletin* de la Société d'Encouragement pour l'Industrie Nationale contains an account of an interesting application of electric-power transmission to cottage industries. The district of St. Etienne is largely engaged in the manufacture of ribbons; the looms, being situated in the houses of the weavers, were until lately driven by human agency. Many of these are now driven by electro-motors, the generating station being situated at St. Victor-sur-Loire, nine miles away, where three turbines, each of 300H.P., have been fixed. The power company now serve 24 communes, the distribution being on the three-phase system. The cables have a total length of over 68 miles, the electromotive force on the transmission line is 5,200 volts, which is reduced by transformers to 190 volts for the house circuits. About 2,500 looms are now driven in this way, and the company has also a large lighting load. Each loom takes about a ¼H.P., on which 10fr. a month is paid.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96218.]—**Charging Accumulators.**—You can best charge these from your plating dynamo by putting the cells in parallel groups of two in series. The proper charging current must be ascertained from the maker's catalogue. Supposing a charge of 10 ampères be permissible, then you will be able to put as many as five groups in parallel of two cells each without exceeding the capacity of the dynamo. The conditions of the cells can be ascertained by (*a*) testing their individual voltage, which should rise to 2·3 or 2·4 at the end of the charge; (*b*) by taking the specific gravity of the electrolyte, which is generally about 1·195 to 1·200 when fully charged; and (*c*) by observing the appearance of the electrolyte, whether "milky," and if gas is evolved freely. The positive plates should turn a chocolate, or even a plum, colour; but experience is the only safe guide. See the many hints given in back numbers. A. H. Avery, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96304.]—**American Organ.**—In reply to "Organon" (p. 43), absence from the vicinity of the Patent Office prevents me sending exact details of the organ. I will look them up on my return to town. The name of the patentee was R. Willard Paine, and the date was somewhere in 1896. The organ was adapted for automatic playing, and was divided into two parts, one containing the two reservoirs and feeders driven by an electro-motor, and the other containing the reeds, pneumatic action, and a piano with pneumatic hammers. In such an instrument as the Æolian automatic organ, I have found the action quite as quick when there is there is the least possible suction that will make the reeds speak as when the reservoir is fully drawn up. H. Bevan Swift.

[96364.]—**Steam Barge.**—Query imperfect. Is the barge to go with stream or against an ebb?—because that makes a great difference. This kind of query has been frequently answered in back volumes; but it seems useless to point out that "conditions alter cases." Metors.

[96367.]—**Perforating and Cutting Paper.**—Punches for cutting paper, or even leather, can be obtained from any of the makers. Nowadays iron and steel are cut by that method when power is available; but as an example, such leather work as gentlemen's "braces" is often punched by the hand hammer and tool. Any of the ordinary toolshops keep such punches. A block of lead (soft) is about the best material to punch on. T. L.

[96426.]—**Magnetism.**—There is no known substance, either liquid or metallic, which will "insulate" magnetism. The only way to isolate a magnetic field is to intercept the lines of force, and offer them a path of less resistance than their air-circuit, such as a closed circuit of iron. This has an effect similar to shunting a current, and the analogy holds good insomuch as it is impossible to deflect *all* the lines of force unless the shunt or iron circuit possesses absolutely no resistance or reluctance.
A. H. Avery, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96452.]—**Meal Powder.**—Forty years ago I used to make my own thus:—Saltpetre 15 parts, flowers of sulphur 2 parts, ground charcoal 3 parts. It answered admirably for rockets. The saltpetre was crude, pulverised by the simple boiling down and vigorous stirring, and suddenly cooling, when it resembled moist salt, then hung up to dry in paper. This mixture is, in fact, gunpowder, but not granulated. Hammer.

[96439.]—**Quadratic.**—To "Ontario" and "Scorpio."—Will the friend who informed "Ontario" that his equation could be solved by quadratics kindly show your readers how it can be done? Unless he can resolve it into two quadratic factors equateable to zero, his statement must be inaccurate, especially as the values obtained by myself (and still more accurate ones by "Scorpio") point to the non-existence of rational factors, or, at least, to a fundamental difficulty in finding them. The equation is certainly not a quadratic, but one of four forms which the biquadratic,

$$81x^4 - 1368x^3 - 3332x^2 + 35772x + 95832 = 0,$$

may assume, whether expressed integrally or as—

$$\pm\sqrt{x+3} \pm \sqrt{\frac{x-2}{x+3}} = 3\tfrac{2}{3}.$$

If we put $\sqrt{x+3} = y$, we may change the form to—

$$[y(3y - 11)]^2 = 9(y^2 - 5),$$

where $y = 3, 4·5367, -·1017 \pm ·59747\sqrt{-1}$. For some time I have been inviting mathematicians to re-examine the theory of equational roots, and this equation again proves the importance of such re-consideration. Every equation has one proper solution only, when strict regard is paid to form. Every additional value of x means either a change of value or of form in the original equation; in other words, fresh equations. The normal and inverse processes of multiplication lead to normal and inverse powers and roots. Equational principles demand that the same process shall be applied to each branch. Thus, if $x^2 = a^2$, we may deduce (i) $x = a$, (ii) $-x = -a$, but not (iii) $x = \pm a$, which involves two distinct primaries, for if—

$$x^2 = a^2,\ x = a, \text{ or } -x = -a.$$

Again, if we take normal or positive roots.

If— $(x - a)^2 = a^2,\ x - a = a,\ x = 2a;$
If— $(a - x)^2 = a^2,\ a - x = a,\ x = 0.$

If we take inverse roots, then—

$$-(x - a) = -a, \text{ or } x = 2a;$$
$$-(a - x) = -a, \text{ or } x = 0.$$

Lastly, since $(x - a) = a$ is a different equation from $(a - x) = a$, so $(x - a)^2 = a^2$ is a different quadratic from $(a - x)^2 = a^2$, and the dual solutions strictly arise from a change in the primary, which is formally inadmissible.
West Norwood, Sept. 2. Henry T. Burgess.

[96461.]—**The Mineral Waters of Germany.**—Much obliged to those correspondents who have replied to my query; but may I ask them whether it is true that patients are warned not to eat fresh fruit at the time they are taking the waters? If so, what can be the reason? Does the acid of the fruits act injuriously when taken with the waters, and if so, what is the cause? Lithia.

[96471.]—**Loan Amortisation.**—In this reply on p. 71, the word "extraction" should, of course, be extinction. B. D.

[96471.]—**Loan Amortisation.**—I did not notice "X.'s" original query, and, being away from home, cannot refer; but his table in this week's number (Sept. 1) is useless for comparison purposes, because he is treating one loan at 3½ per cent., and the other at 4½. To be of any use the same rate should be used. R. H.

[96480.]—**Preserving Flying Fish.**—In this reply on p. 71, why should alcohol of 95 per cent. be diluted with two parts of water? Seems that a weaker alcohol would do, without diluting the more expensive spirit. Perhaps "Regent's Park" will kindly explain. It seems to be a waste of money to purchase strong alcohol and then dilute it with water. Perhaps there is something which does not appear in the reply. M. S. T.

[96482.]—**Insects in Floor.**—A wooden floor over soil is pretty sure to be destroyed by dry-rot, unless the boards are ill-fitting—ventilation is the only preventive. A cottage ground floor should be solid concrete all round the walls for 9in. or so; surbase also concrete; ventilation through walls and concrete below the joists by a common drain tile, protected outside by a perforated vermin-proof brick. This is perfect until the tenant plugs up the ventilation, which he generally does. Hammer.

[96488.]—**Pitch of Worm.**—As this simple query seems strangely enough to have been as yet passed over by your numerous mechanical correspondents, and as the reply of "Regent's Park" is totally inapplicable to the case, I now venture to trespass on the extensive field covered by your encyclopædic correspondent. The reply at p. 71 refers to wheels, not to "worms" or screws. Besides, even as applied to wheels, the method there quoted is now almost obsolete, since the general introduction in this country of the "Manchester Diametrical Pitch," which, as we all know, refers to the number of teeth in the space of the diameter of the pitch circle, without any reference to the number of teeth per inch. For "worms," which are simply coarse screws of single or multiple pitch (generally the latter), a totally different method applies. Indeed, the querist himself, by mentioning the change rigging up of change-wheels to find the pitch, knew better than to suppose his problem had any relation to the subject raked up by his informant (?) at p. 71. It it be possible for a man to have worked a week among screws without finding out for himself the means of measuring pitches accurately in threads per inch or per cm., I beg to be excused wasting space in trying to inform him. Lay alongside the "worm" or screw, and perfectly parallel to its axis, a rule or scale divided in any grade of divisions, moderately fine divisions being preferable. (Of course, only by the merest chance will a scale be at hand whose divisions correspond with the screw-threads, or are even aliquot parts of them.) Cause one perfect thread at the end of the screw to coincide with a division of the rule or scale, then pass the eye along (best if assisted by a watchmaker's glass stuck on it), till it is noticed where the screw-threads and the scale divisions again coincide. If, on the length of screw available, no second coincidence takes place, try a scale of some other division. In all cases take as great a distance between the two coincidences as the length of screw permits of, if great accuracy be required. If of V-pattern, make the exact centre, as near as can be

estimated, of the first *thread* measured from, coincide with one of the scale divisions, and seeing to the equally perfect alignment at the next coincidence, count the number of *spaces* included between these limits, counting both the *spaces* of the screw-threads and the *spaces* of the scale applied to it. If of square-thread pattern, make the coincidences with, say, the right-hand margin of a thread (i.e., the beginning of a space), and count, as above, the included *spaces*. Then, if the screw or "worm" be of single thread (known by having but one beginning, work out the simple proportion which the screw-threads bear to the divisions of the scale employed to measure them. Take a case:—Let the screw or "worm" be single-threaded, and the scale employed one divided in $\frac{1}{16}$ths of inches. With a coincidence of thread centre and scale division, say, at the left hand, the next coincidence happens towards the right, including a space which takes in three *spaces* of the screw, and 20 *spaces* of the scale. As in the ordinary use of the foot-rule the initial line is zero, and it is only the spaces we count.) Here, therefore, we have the proportion 20 : 16 : : 3 : 2·4, or, more simply $\frac{16 \times 3}{20} = 2{\cdot}4$, so that our screw has $2\frac{4}{10}$ threads to the inch. If the screw as above be "coarser" than the scale used to measure it, we multiply the scale grade by the smaller number (three here) and divide by the larger (20 here). The reverse when the screw is "finer" than the scale dimensions. Again, other scales may be used (say for testing results) thus:— $\frac{12 \times 2}{10} = 2{\cdot}4$, which gives the same measurement of our screw, made in this instance by a scale divided in $\frac{1}{12}$th of inches. Lastly, the "worm" or screw may be multiple-threaded, in which case, simply count the number of beginnings it has, and divide the "pitch" as found above by that number. For example, if double-threaded, we should have $\frac{2{\cdot}4}{2} = 1{\cdot}2$ threads per inch. If triple-threaded, $\frac{2{\cdot}4}{3}$ = ·8 threads per inch—i.e., 4 threads in 5in., and it is to these pitches as finally found that we set our change-wheels. H.

[96491.]—**Electrical.**—If "S. B. G." refers to Wright's maximum demand indicator, I gave a sketch and description of that in the "E. M." not very long ago. I cannot put my hand on the exact number, but it certainly was not more than two years ago. A. H. Avery, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96504.]—**Macadam.**—Why not refer to the author's own works: "A Practical Essay" (1819), "Remarks" (1820), and "Observations" (1822)? J. Dormer.

[96512.]—**Electric Lighting.**—Provided no public supply of current is available, about the most economical way of going to work is to install a ½B.H.P. gas or oil-engine and a 30-volt 4 ampère Lahmeyer dynamo. A couple of switches and a few yards of cables and lamps will complete the outfit, which need not exceed £10 in cost for first-rate articles. For temporary work the wires need not be cased in, but simply suspended by insulated eyes and hooks. I can help "A. R. P." further on receipt of his address.
A. H. Avery, A.Inst.E E.
Fulmen Works, Tunbridge Wells.

[96513.]—**Hereditary Insanity.**—No answer of any value can be given to such questions. The probabilities are all in favour of sanity, if the children lead healthy lives. J. D.

[96519.]—**Water Power.**—A pipe 100ft. long with 10ft. head, and one 1,000ft. long with 100ft. head, have the same maximum carrying power. They would each discharge, under the conditions named, about 344 gallons a minute "freely into space"; but a much greater horse-power may be got out of the long pipe than out of the short one. The maximum power in either case would be obtained by arranging the quantity of water used so that about a third of the head is utilised in overcoming the friction in the pipes, leaving the remaining two-thirds to generate power. With a loss of head of 40ft., leaving 60ft. useful pressure, the 1,000ft. pipe will pass about 210 gallons a minute—i.e., 2,100lb. falling 60ft. = 126,000ft.-lb. per minute, or, roughly, 3¾H.P. The querist will see, on working out the short pipe by the same figures, that only a tenth or so of that power could be got from it. W. Wyatt.

[96521.]—**Speed of Falling Chain.**—Mr. Carnegie is, I take it, wrong in his answer to the above. The chain will acquire a uniform velocity equal to that of a body falling freely through the distance between the pulley and the bottom of the pit, and the tension at any point of the chain will be represented by the weight of that portion of the chain between the said point and the ground. The uniform velocity acquired will thus, in this case, be given by $v = \sqrt{(2 \times g \times 580)}$. It is obvious that this must be so from the principles of the conservation of energy; every pound weight of chain at the level of the pulley has 580ft.-lb. of potential energy in it, due to its height above the bottom of the pit, and this must be converted after it has fallen 580ft. into 580ft.-lb. of kinetic energy. And how can this be the case unless the uniform velocity acquired be $\sqrt{2gh}$, where h = 580ft.? It is true that the first 580ft. of the chain that descends will not have this velocity, since its energy will be partly employed in accelerating the portion descending above it; but the kinetic energy that thus disappears is restored when the last 580ft. of the chain descends, the kinetic energy of which will be just as much in excess of $\sqrt{2gh}$ as that of the first 580ft. fell short of it. P. B.

[96522.]—**Electric Motor.**—Carcase of the Lahmeyer type: Armature bore, 7in. diameter by 7in. long; pole-pieces, 7in. deep by 5¼in. high by 3in.; winding space, yokes, 7in. deep by 2¾in. wide; distance between yokes and pole-pieces 3in.; armature, drum wound, 32 (or more) sections, 10lb. No. 20 S.W.G. in four layers; core discs, 6¾in. diameter; field winding for shunt machine, 30lb. No. 23 S.W.G.; speed, about 1,800 revs. (This corresponds to my "No. 7 Lahmeyer.") (1) About ⅛ B.H.P. (2) The drum, if properly insulated. A Lahmeyer motor of this size, with a 2½in. by 3½in. armature, takes 12oz. No. 30 on the armature, and 3½lb. No. 32 on the fields in shunt. (3) See preceding. (4) Yes, with a resistance in series with the main circuit: the normal speed for this size machine is 2,600 revs. A 10-ohm resistance would have hardly any perceptible effect, unless placed in series with the armature only. (5) "Doctors differ"; in larger machines probably yes, but in small ones decidely no.
A. H. Avery, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96523.]—**Water Lifting.**—Thanks very much to "M." for his reply to my question. I think this seems the best plan I can adopt. At the same time I shall be very pleased to hear a suggestion by "Trytoaid," and to his question I reply that the tank is to be emptied twice weekly perpetually. Redbun.

[96524.]—**Automatic Flushing Tanks.**—Siphon having widened overflow and discharged latter sealed in water trap below, so that the air may be compressed in the siphon before the water falls over lip and starts it, is a general arrangement. Another one is a water-tight valve in tank, balanced at opposite end of lever by small tank. Overflow of large tank fills small tank and overbalances lever, raising large valve and flushing. A siphon pipe from small cistern into large one is started by rush of water, empties small cistern back into large one; valve closes, and tank collects water once more. See W. R. Maguire's "Domestic, Sanitary," &c., and many others. Regent's Park.

[96528.]—**Chemical Action.**—An unfortunate misprint has occurred in my reply. The last term of the equations should read $5O_2$ instead of SO_2.
Trin. Coll. Oxon. J. M. W.

[96530.]—**Alternator.**—The use of the synchroniser is, of course, to get the various currents "into step"; without it, although the alternators might be running at precisely the same speeds, it would be possible to have them differing in phase, so the impulses of their respective E.M.F.'s were opposing, and consequently the available current at the bus-bars little or nothing. It is certainly inadvisable to parallel alternators by different makers, as the wave form seldom coincides, and would thus give rise to various trouble internally.
A. H. Avery, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96531.]—**Heating Power of Coal.**—A search through such publications as the *Minutes* of the Institutes of Civil, Mechanical, and Electrical Engineers would yield the information required. The accompanying table, taken from "Hutton's Works Manager's Handbook," may be of service. It may safely be assumed that on the average not more than 47 per cent. of the theoretical heating power of fuel is utilised, the remainder being lost through imperfect combustion, radiation, and other causes. In the "E. M." Vol. XLIX. p. 356, there is a notice of a paper on "The Heat-Producing Powers of Twelve Samples of Coal," contribubed by W. Thompson to the Manchester Section of the Society of Chemical Industry at a "recent" (1889) meeting. The figures given in the extract are: Anthracite 8,340 Centigrade units, Pendleton 7,736 units, Wigan 7,552 units, Atherton (lowest of the twelve) 6,448 units. In two cases the experimental results were higher than the theoretical, in two cases equal, and in the remainder lower. In calculating the theoretical heating power from the analysis of a given sample, 1lb. of carbon may be taken as yielding by its combustion 14,500 Fahrenheit units, 1lb. of hydrogen 62,032 units, and 1lb. of sulphur 4,032 units. It is usual to deduct from the total percentage of hydrogen present a quantity equal to one-eighth part of the oxygen with which it exists in combination as water. The writer of the above-mentioned paper, however, appears, as far as I can gather, to have considered it necessary to deduct hydrogen corresponding to the whole of the oxygen present, which would, of course, lower his theoretical results considerably. W. J. G. F.

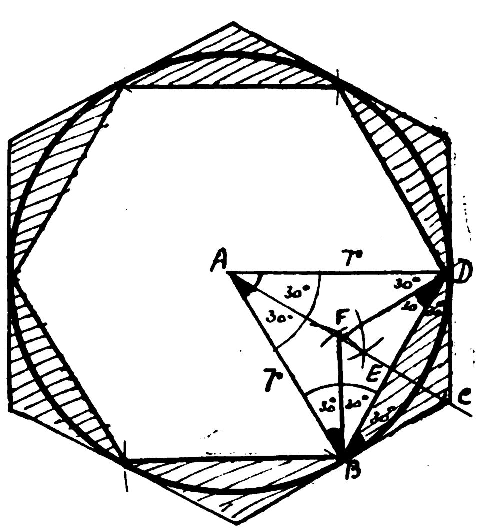
[96539.]—**Ebonite Boxes.**—If indiarubber cement is not possible, following may answer:—Resin 5lb., beeswax 1lb., red ochre 1lb., plaster of Paris 4oz.; continue heat little above 212° Fahr., stir till frothing ceases; or resin 6lb., red ochre (dried) 1lb., calcined plaster of Paris ½lb., linseed oil ¼lb.; or stir into solution of soluble glass finely pulverised chalk (sol. glass of 30° B.) until mixture is fine and plastic; hardens in six to eight hours, &c.
Regent's Park.

[96550.]—**Mensuration.**—In diagram area of shaded portion is 813sq.in. A B D is an equilateral



triangle, six of which make up the interior hexagon. Bisect the angles A B E, A D E by the straight lines B F, D F. Then the four triangles A F B, A F D, B F D, B C D are equal in area, for each has two equal sides and two equal angles. (See diagram.) ∴ area of triangle A B D = three times area of triangle B C D. ∴ area of int. hexagon = three times difference of areas of the two hexagons. ∴ area of interior hexagon = 3 × 813sq.in. = 2,439sq.in.; but area of hexagon having a side, "r"—

$$= \frac{6 \times \sqrt{3}\,r^2}{4} \therefore r^2 = \frac{2{,}439 \times 4}{6 \times \sqrt{3}} = 542\sqrt{3}\text{sq.in.}$$

but area of a circle having radius "r" = 3·14159 × r^2. ∴ area of circle = 542 $\sqrt{3}$ × 3·1459sq.in. = 2,947·44602118sq.in.
Lancaster. John Shaw.

[96544.]—**Lard Refining.**—In my previous reply I omitted to state the commercial uses of lard-oil: edible, lubricating, wool-softening, and

also for adulteration of olive and spermaceti oils, being cheaper. Sp.gr. of 0 9165 to 0 9200 at 15° C., and setting point of −1° to −5° C. By pressing hog's lard at zero C., lard-oil, which does not set at even comparatively low temperatures, is obtained, leaving behind tallow (margarine, palmatitin, and stearine), useful for candles, &c. Pure hog-fat is used as medicine for ointments, pomades, creams, &c., alimental, edible, and cooking foods. "Animal Fats and Oils," by L. E. Andés, of Scott, Greenwood, and Co., London, E.C., 1898.

REGENT'S PARK.

[96553.]—**Astronomical.**—The method mentioned by "Jancis" for solving the astronomical triangle when the latitude and sun's dec. are of opposite names is quite correct. In so doing we would be solving the triangle formed by the zenith, sun, and depressed pole (beneath horizon), and would obtain the value of the angle at the depressed pole, which would be the sun's hour-angle. But it would be more natural to solve the triangle formed by zenith, sun, and elevated pole. We would then use for colat. 90°−lat. and for polar dist. 90°+dec. The results would be identical. ARCTURUS.

[96554.]—**Magnetism.**—You can magnetise even better with the horseshoe, provided, of course, you place the magnet down on the needle with opposite poles facing—i.e., N. to S. and S to N.—and remember to lift off when the needle lies equidistant between the poles of the horseshoe. But you can keep your bar-magnet strong if, when you put it away, it is placed between the jaws of a piece of well-fitting soft iron of this shape |_____|. To be efficient, this piece of soft iron or "armature" should be of the same general thickness and width as the base itself. S. BOTTONE.

[96555.]—**Equations.**—Simultaneous equations of the kind referred to by Mr. Harding require usually some algebraical device in their solution. Some involve equations of a higher degree than that expressed in the given equations, and are often insoluble; others require recourse to the various complicated theories of elimination embodied in "higher" algebra. In the present example, if we observe the symmetry of the coefficients—viz.:

$$\left.\begin{array}{l}\text{(i) } \tfrac{2}{3}x^2 + \tfrac{3}{5}yz = 6\tfrac{3}{4} \\ \text{(ii) } \tfrac{3}{5}y^2 + \tfrac{5}{7}xz = 7\tfrac{1}{2} \\ \text{(iii) } \tfrac{5}{7}z^2 + \tfrac{7}{9}xy = 11\tfrac{2}{3}\end{array}\right\}$$

—we may assume x to be fractional and the reciprocal of the coefficient of x^2—viz., $\frac{3}{2}$—whence:

$$\tfrac{2}{3}x^2 = \tfrac{2}{3} \times \tfrac{3}{2} \times \tfrac{3}{2} = \tfrac{3}{2}.$$

$$\therefore\ \tfrac{3}{5}yz = 6\tfrac{3}{4} - \tfrac{3}{2} = \tfrac{21}{4},$$

and— $$y = \frac{35}{4z}.$$

Substituting these values of x and y in (ii) and (iii), and reducing, we get—

$$\text{(iv) } \tfrac{15}{14}z^3 - \tfrac{15}{2}z^2 + \tfrac{735}{16} = 0$$

$$\text{(v) } \tfrac{5}{7}z^3 - \tfrac{35}{3}z + \tfrac{245}{24} = 0.$$

Multiplying (v) by $\frac{3}{2}$ and subtracting it from (iv), we get—

$$\text{(vi) } -\tfrac{15}{2}z^2 + \tfrac{35}{2}z + \tfrac{490}{16} = 0.$$

Change signs and $\times \frac{2}{15}$:

$$z^2 - \tfrac{7}{3}z - \tfrac{49}{12} = 0.$$

$$\therefore\ z = 3\tfrac{1}{2},\ y = \frac{35}{4z} = \tfrac{35}{14} = 2\tfrac{1}{2},\ x = 1\tfrac{1}{2}.$$

The secondary values $-1\frac{1}{6}$, $-7\frac{1}{2}$, $-1\frac{1}{2}$ do *not* satisfy the given system of equations.

West Norwood. HENRY T. BURGESS.

[96556.]—**Oil and Gas Engines.**—Capacity of motor cylinder to combustion chamber is about 2¾ to 1. Test by filling space swept by piston with water; which measured in suitable vessel compare with quantity combustion chamber holds. This proportion gives about 65lb. compression, for which it is usual to allow six times this pressure, when designing for strength of parts. I cannot go further into matter here. Get last edition of Clerk on gas and oil engines at nearest free library for full information. It is a very good work. MONTY.

[96557.]—**Window Cases.**—You cannot do better than send 1s. to Birkenhead, Sale, Manchester, for his little fern book, which gives exactly the information you require. J. D.

[96558.]—**Injector.**—You do not state if injector is lifting water or taking it from town main, which makes a difference. Steam pipes to supply injectors must be taken direct from boiler top, never connect with a steam-pipe used for any other purpose. I enumerate a few causes likely to prevent injector working. 1. No water, leaks in suction-pipe; strainer blocked, want of a check-valve in end of suction pipe—if a long one; air leak in valve-stem of suction-pipe valve, often unsuspected, which repack to cure; too high pressure for long lift; dirt in pipes, iron scale, &c.; a bad check-valve, not lifting enough, or not at all—all checks for injectors want more lift than for a pump to work well; valve in suction-pipe not regulated below pressure wherein can be thrown wide open; loose disc on water-supply valve, or valve put on wrong way—i.e., pressure on top causes loose disc to close automatically; wet steam, foaming boiler; water-supply too hot; air in pipe between boiler and injector—remedy, put pet-cock in a tee piece between, which open a few seconds on starting; injector jets may be limed up—to clean, soak in water to which hydrochloric acid has been added in proportion of 1 part acid to 12 water. Cut reply out and paste up near kettle, as faults and remedies are not given in standard works on injectors.

MONTY.

[96558.]—**Injector.**—We should suppose you are taking steam for injector from the pipe supplying steam to engine. If so, the remedy is obvious—viz., take it from the boiler.

WEBSTER MICHELSON AND CO.

[96559.]—**Billiard Table.**—First remove the pocket-plates, and then the cushions. To remove the cushions, take out the plugs along the front, and then unscrew the bolts exposed. Remove the old cloth by pulling out the tacks or by cutting it round underneath the table. The old tacks will not hurt being left in. See which is the right side of the new cloth, and in which direction the "nap" runs. Lay the cloth on the table so that the nap runs from the baulk end to the spot end. Place it about centrally, and then put a couple of strong tacks in at the centre of one end. Go to the other end and take a good handful of cloth, and pull hard, putting two tacks in the middle when the cloth is as tight as possible. Then go to one middle pocket, and pull moderately hard, putting a tack in on each side of the pocket. Then go to the other pocket, and pull hard, tacking again on each side. Be careful to keep the centre line of the cloth straight. Now go to each corner pocket, and pull hard, tacking on each side of the pockets. Do not mind about wrinkles over the pockets at present. Now tack the cloth down between the pockets, pulling it tight each time. The cloth will now have to be carefully coaxed over the pockets, and only patience will bring about a satisfactory result. The centre pockets especially will need great care. When the cloth is successfully stretched, the cushions and pocket-plates may be put on again, and the pockets tacked underneath. If the cushions are capable of longitudinal adjustment, care must be taken to get all the pockets of the same size. When putting on the cushions do not screw each bolt up tight as you put it in, but screw all of them up fairly tight, and then fully tighten them. Reclothing the cushions is a job beyond an amateur not practised in it, and should on no account be attempted, being sure to result in failure. H. W. A.

[96560.]—**Perspiring Hands.**—After having washed the hands, allow the tap to run on them for a few minutes. I have found this an effectual cure.

J. WIGHT.

[96561.]—**Perspiring Hands.**—Best to have a free skin, but if you elect to reduce, try washing once a day (not oftener) for about two minutes with liquor atropiæ 2 drachms, water 1 pint. The face and other parts may also be washed as often as desired with alum 1oz., glycerine 1oz., water 10oz. Powder for hands and feet:—Carbolic acid 1, burnt alum 4, starch 200, French chalk 50, oil of lemon 2. REGENT'S PARK.

[96563.]—**Belting.**—Let L = length required, D and d = diameters of pulleys, C = distance of centres, D + d = S. For a crossed belt—

$$L = \left(\frac{\pi}{2} + \theta\right) S + 2C \cdot \cos\theta$$

where— $\sin\theta = S \div 2C$.

For an open belt—

$$L = \frac{\pi}{2}(D + d) + \theta(D - d) + 2C \cdot \cos\theta$$

where— $\sin\theta = (D - d) \div 2C$.

J. WIGHT.

[96564.]—**Organ for the House.**—In my query I gave the size of bellows 48 by 24. It should be 54 by 24.—PIPE ORGAN.

[96564.]—**Organ for the House.**—I am afraid you will find your bellows too small for the instrument you propose. You cannot do better than follow the specification and instructions given a short time since in the ENGLISH MECHANIC on building a small two-manual pipe organ. Pedals (independent) could be added, acting on separate pedal organ. The organ described will give every satisfaction as a practice instrument, and considerable variety can be obtained from it. Surely your specification is wrong: only one 8ft. stop out of six?—this would never do. Or do you mean that the largest stopped wood pipe is only 4ft. on the manuals, thus giving the 8ft. tone. If you only wanted the instrument for practice purposes, one stop on each manual would be sufficient, with full compass pedals and usual couplers. If you like to advertise your address in the Address Column of "Ours," I shall be pleased to communicate with you, and advise you as to the best kind of instrument for your purpose. DIAPASON.

[96565.]—**Dynamo for Nickel-Plating.**—The plan suggested is not feasible, as there is a certain "critical speed," below which the dynamo will not excite itself. The only course open is to put a resistance in series with the shunt-coils, which, by cutting down the magnetising current, will reduce the volts to any desired extent; but, of course, no more than 8 ampères must be taken from the armature. A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[96565.]—**Dynamo for Nickel-Plating.**—Although it would be possible to reduce the voltage from 50v. to 6v. (that required for nickelling) by running the dynamo at a lower speed, yet it would hardly be worth while so to do, since the current in ampères would fall in like proportion, so that the available current would only be a fraction of an ampère. Your best plan would be to get a spare armature made, wound with coarse wire, so as to give about 6 volts and 40 to 50 ampères. With a properly arranged switch, you could put the F.M. coils in parallel or series at will, so that you could use the two armatures, and either light or plate at your option. S. BOTTONE.

[96565.]—**Dynamo for Nickel-Plating.**—You can do as you mention by running very slow; but you would do better by having a dynamo specially constructed for plating purposes.

WEBSTER MICHELSON AND CO.

[96566.]—**Motor Cycles.**—By all means fit your "trike" with electric ignition, and, as soon as fitted, try to understand working of same, as it is really quite simple; it gives about 25 per cent. more power than lamp, especially on hills. I have given both methods a long trial, and find there is simply no comparison. Sims' magneto-ignition would be as cheap for you to fit as usual batteries; and give far better results. Magnets are permanent, and would run about two years before requiring remagnetising. You can easily get a vacuum valve put on top of 2 to 1 gear-case cover, where you will find a boss for purpose—simply a plug of brass ½in. diameter, fine thread, into which another plug is fitted; holes drilled $\frac{1}{16}$in. diameter right through both plugs. A $\frac{1}{16}$in. cycle ball is placed between the plugs, allowing $\frac{1}{16}$in. lift. Be sure have a ⅛in. hole drilled just below small gear-wheel through crank-case, to allow oil to return; you will find one also at back of foot on valve-rod. Your engine is probably one of old 1¼H.P.; it should be worth alterations. MONTY.

[96567.]—**Dry Pile.**—I do not think you can look for luminous (which means heating) effects from the dry piles, because their resistance is so enormous that their current is infinitesimal. But it seems probable with a modification of the old dry pile in the direction of the secondary battery. This might be done by using peroxide of lead on a paper containing or coated with some of the gelatinous preparations used in the so-called dry cells, and using precipitated lead instead of the usual tin. A series of these might be charged occasionally by means of Wimshurst machine. This suggestion, of course, needs a little experiment and working out; but I think something useful might be made of it. SIGMA.

[96567.]—**Dry Pile.**—To "SIGMA" OR MR. BOTTONE.—I do not think you could get the desired effect from a dry pile; certainly not with any degree of permanence. With a pile of some 50,000 or 60,000 alternations you might get weak ⅛in. sparks, but no permanent result, except, of course, that the opposite poles will show opposite polarity for a very long time—say a year or two—if not short-circuited too frequently. Why not use a small electrophorus? This is easy to make, cheap, and quite efficient in producing the fluorescent effect. You can use red-lead instead of peroxide of manganese. S. BOTTONE.

[96568.]—**Palms.**—Use electricity for illuminating your drawing-room. Your palms will not then suffer. WEBSTER MICHELSON AND CO.

[96568.]—**Palms.**—The reason may be sought in insufficiency of light, air fouled by gas, inattention to watering, or air too dry. J. D.

[96569.]—**Phonograph for Recording Music.**—No difficulty should be experienced in taking a record with the Edison home phonograph, providing you use a large horn about 30in. long, and 15in. diameter at the mouth. This is attached to the diaphragm case by a short length of rubber tubing, and the musicians arranged in a semicircle in front of the horn. A special room is not absolutely necessary. A much louder sound can be produced by using a "Bettini" reproducer, or a "polyphone" attachment, as illustrated in last week's issue. If very loud reproductions are required, a machine having six diaphragms, and recording the music of each instrument separately, and reproducing all simultaneously, would be much better. F. F.

[96569.]—**Phonograph for Recording Music.**—Only to-day (September 1st) by a curious coincidence I saw a cripple on our Thames Embankment (Victoria) who had a small apparatus (whether Edison's or no cannot say), circular disc, wound

up by spring clockwork motion no doubt, with trumpet projection. The sound was sufficiently powerful for me to hear it 50ft. or 60ft. away. It was reproducing music-hall ditties. The same day I was in Cheapside, and saw in window at western end a stock of loud reproducing Edison's from £2 to £50, or even more, for large or small, commercial, and domestic purposes, and no doubt to be heard of at Calcutta, if not at Moulmein or Rangoon. Perhaps (if not already fitted with trumpet attachment) you could have one fitted to your machine. It may be the older pattern with ear-discs and cords attachment. REGENT'S PARK.

[96571.]—**Electro-Motor.**—To MR BOTTONE.—It will be a great advantage to replace the solid H by a laminated one. The H form is rather more efficient (powerful, with a given current) than the tripolar; but, on the other hand, the tripolar is virtually self-starting in any position when the current is turned on, which the H form is not. This refers to its work as a motor, for which it is well adapted. As a dynamo there is little difference; but the Siemens H is good for lighting and general experimental work, but *not* for electrolysis or accumulator charging, while the tripolar works well for these purposes. It will be convenient to have a sliding resistance to regulate speed if used as a motor. S. BOTTONE.

[96572.]—**Spark Coil.**—To MR. BOTTONE.—Your proportions are perfectly correct, and if the coil is well made and the secondary well insulated from the primary by a good stout ebonite tube, it will give a 1in. spark, which can be shortened to $\frac{3}{8}$in. gap, to get a good *hot* fat spark. S. BOTTONE.

[96573.]—**Steamy Windows.**—If S. Watson puts a saucer of sulphuric acid at the bottom of window, it will absorb the moisture. W. T. S.

[96573.]—**Steamy Windows.** — Glycerine is very useful as a preventive of steamy windows. Clean the glass, and polish off with glycerine. F. PRINGLE.

[96573.]—**Steamy Windows.** — Clean your windows with cloths moistened with glycerine. J. H. S.

[96575.] — **Small Dynamo.** — Construct a machine of the Lahmeyer type, after the same general lines as that illustrated in the "E.M." for May 7, 1897, making the armature 2in. in diameter by 1in. long. This should be wound as an 8-part drum, with 2oz. No. 24, and the fields with 8oz. of No. 21in. shunt. At a speed of about 1,000revs. per minute, this should develop 4v. 2A., and take 440ft.lb. per minute to drive. The idea of driving by means of a weight is not very practicable, as either a very heavy weight or a very long fall is necessary to keep the light going for any length of time. A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96575.]—**Small Dynamo.**—It would seem hardly worth the trouble and expense to construct a dynamo for so very small an output as 8 watts. Probably a battery of three dry cells would be more satisfactory for such as the querist's purpose. However, in the following is given particulars of the little machine desired. Output, 2 ampères at 4 volts; armature, Siemens "H-girder" or shuttle type, laminated; size, $1\frac{3}{4}$in. long by $1\frac{1}{4}$in. diameter, with with winding spaces $\frac{3}{8}$in. by $\frac{5}{16}$in.; speed, 3,300 revolutions per minute. Wire on armature No. 22 S.W.G. silk-covered copper, 120 complete turns = $18\frac{1}{2}$ yards = 2oz. approximately. Field-magnet, overtype or undertype, wrought iron; size, 4in. high by $2\frac{3}{8}$in. wide; cores and yoke (in one piece), $\frac{3}{8}$in. thick by $1\frac{3}{4}$in. deep—i.e., in direction of armature's length. Pole-pieces bored $1\frac{5}{16}$in. diameter. Wire on fields, No. 22 S.W.G. silk-covered copper, 756 turns = 122 yards = $13\frac{1}{2}$oz. Tinplate bobbins, for field-windings, 2in. long, with sheet-brass cheeks $2\frac{1}{16}$in. by $1\frac{5}{16}$in., winding in each seven layers of 54 turns. Field-windings to be connected in shunt with the armature. Probable efficiency of the machine, about 60 per cent. Driving power required, $\frac{1}{57}$B.H.P. With regard to the proposal of employing gravity as a motor on the clock-movement system, it can be shown arithmetically that such an idea is almost practically impossible. As stated, the dynamo needs $\frac{1}{57}$B.H.P., making the work to be done $33{,}000 \times \frac{1}{57} = 579$ft.lb. per minute approximately. If the drop to be allowed for a weight is 10ft., and the motor is required to run two hours for once "winding," the rate of fall will be $\frac{10}{2 \times 60} = 0{\cdot}0833$ (&c.) ft. per minute, and, therefore, the necessary weight must be $\frac{579}{0{\cdot}0833}$ $= 6{,}950{\cdot}79$lb. But it is probable that the train of wheels required to convert the weight's motion into usable form may not have a higher efficiency than 80 per cent., if so high, so that the actual weight should be, at least, $6{,}950{\cdot}79 \times \frac{100}{80} = 8{,}688{\cdot}5$lb. (nearly). This reply may also interest your correspondent, F. D. C. Baly, letter 42715, p. 38. D. W. GAWN.

[96575.]—**Small Dynamo.**—Armature laminated, H pattern, 2in. long, 1in. diameter, wound with 18yd. No. 24 silk-covered copper wire; field-magnets, undertype, 2in. wide, $\frac{1}{2}$in. thick, 4in. high, including tunnel; winding space about 2in. on each limb, wound with seven layers No. 24 silk-covered wire (about $\frac{1}{4}$lb.) on each limb, connected in shunt with the brushes. To get good results the armature must run within $\frac{1}{32}$in. of the jaws of the F.M.'s; speed 3,000 revs. per minute; power required, $\frac{1}{20}$H.P., or, using a weight, 1,375lb., falling through 1ft. per minute. S. BOTTONE.

[96576.]—**Induction Coil.**—For working across 50ft. or 60ft., an induction coil giving $\frac{1}{4}$in. spark will be ample, if you have a good coherer and relay on the receiving instrument. Of course, you know you will require a three-ball transmitter, a key, and a Leyden jar in circuit with the coil at the transmitting end. For the coil, have a core 6in. long, $\frac{1}{2}$in. diameter, wound with $\frac{1}{4}$lb. No. 20 for the primary, a good $\frac{1}{8}$in. ebonite tube over this, and then about 6oz. No. 36 silk-covered copper wire carefully wound on in even layers, each carefully insulated from the superjacent by paraffined paper, for the secondary. Condenser, 50 sheets tinfoil, 4in. by 6in. Battery power, two pint chromic-acid cells in series. S. BOTTONE.

[96578.]—**Subterranean Topography.**—There is considerable literature dealing with caves from archæological, zoological, and palæontological aspects; but I think no comprehensive work describing their formation physiographically. General geological treatises and books by Dawkins, Buckland, Dupont, Putnam, Mitchell, Lartet, and others, furnish an introduction to the subject, which is large and full of varied interest. "Cavernology" would suffice if a name be wanting, for hybrid terms are quite fashionable. J. DORMER.

[96581.]—**Steam Whistle.**—I asked a similar query twelve months ago, to which I could get no practical answer. One thing I found was, using organ-pipe $3\frac{1}{4}$in. diameter 26in. long, $\cdot$180 boiler pressure—lip opening was not enough, causing overtone or unpleasant sound: it was $2\frac{1}{4}$in. at first, and I increased it to $2\frac{3}{4}$in., with beneficial results. Usual length of pipe is eight times the diameter; yours is proportionate. The edges or lips are improved by thinning down to a knife-edge. Should be glad to hear results of your experiments, being interested in the subject. I am afraid you will get six months if you blow such a whistle as you describe anywhere but on a boat. A great improvement is to divide pipe into three chambers of unequal length, producing first, second, and fifth notes; this gives a soft, harmonious musical chord, very penetrating. MONTY.

[96582.]—**Medical Coil.**—To MR. BOTTONE.—Your coil, from your description, is slightly constructed. But you must keep your primary entirely separate from the secondary, not run them together. The clapper is rather too far from the end of core: $\frac{1}{16}$in. would be ample. One pint bichromate cell should give a most powerful shock with this coil. Two cells in series would give a regular "knock-down." S. BOTTONE.

[96583.]—**Tips.**—Would not $\frac{1}{2}$in. lengths of tightly-fitting indiarubber tubing stopped up at the ends (if necessary) with rubber solution answer F. Newton's purpose? B. HARCOURT.

[96584.]—**Removing Rust.**—Some, or all, of these will answer purpose possibly. Soak with petroleum—roughest dark stuff, if you can get it—for several days; it eats into rust, and can be scrubbed off by a wire brush. Brush over nearly saturated solution of chloride of tin, and rest 12, 14, or more hours; clean off; brush over with strong solution of cyanide of potassium—say $\frac{1}{2}$oz. in wine-glass of water—then, with fibre or hair brush, with paste of cyanide of potassium, Castile soap, whitening, and water, to creamy consistency; proportions to be found. Sulphuric acid diluted 1, water 10; afterwards wash with hot lime, water, and dry off with sawdust if possible. Cover with sweet oil well rubbed in; 48 hours after rub with finely pulverised unslaked lime. Whichever of foregoing processes tried, and when fairly clean surface is got and enamel or paint is required, use a good maker's anti-rust; but if, in getting their list, you find they do not sell small quantities to suit you, ask for a retail customer's address most convenient where you can get supplied. REGENT'S PARK.

[96584.]—**Removing Rust.**—Best way, if ironwork is intricate, is to make portable sand-blast out of cycle brazing hearth; sand must be very dry for this. After cleaning, give two good coats of red-lead paint, after which colour as desired. MONTY.

[96585.]—**Bollee Motor.**—Piston should be at bottom of stroke—that is, right out when exhaust valve is wide open, $\frac{1}{8}$in. lift being ample, diam. of valve being about $1\frac{3}{8}$in. as near as I can remember. If not, open correctly, examine 2 to 1 gear for timing. Possibly your carburator spindle is bent, from a blow on side. This would cause float to stick, perhaps getting too much oil, or jet in same may be choked. It is a great improvement on these cars to fit a thin leather disc inside air-inlet cone, at the back of which put a very light spring. To see positions for valve, strike a circle equal in diameter to stroke of engine, cut right across both ways with angle of 60°; at points where lines cross circle will be position of piston, when engine should fire and open to exhaust—assuming engine runs at usual speed, viz., about 600; if above this speed, then 45°, though the latter angle will make it difficult to start against compression. Why not get a book of directions on this motor, which gives some useful illustrations? Price is 1s. MONTY.

[96587.]—**Speed Indicator.**—The Newark trials in 1875 seem to have been estimated by means of electrical apparatus which recorded the instants at which the experimental trains passed over contact pieces placed on rails 200ft. apart. Arrangements well carried out; and Reynolds says the system as a whole was vastly inferior to that of obtaining a continuous record of speeds by means of a speed-indicator. So I suppose "B." could not give particulars *re* those trials, as he had none to give; but, as you know, he does give much on Westinghouse inventions, same page, 188, and on apparently hydraulic speed-indicators. Whether it is "Railways and Locomotives," by Barry and Bramwell, 1882, I am not quite sure. Planimetre.—Polar P. is an instrument for measuring areas, either by actual measurement or to proportional scale, invented by Jacob Amsler, a Swiss mathematician. These are fixed and proportional. Amsler also invented the integrater, which also computes areas, and also gives static momentum and inertia of a plane surface taken in relation to any axis whatever. There is a good deal on this in "Drawing Instruments," by W. F. Stanley, and in one of Van Nostrand's scientific books (New York: 50 cents). Probably B. T. Batsford, 94, High Holborn, W.C., keeps, or could get it for you. REGENT'S PARK.

[96587.]—**Speed Indicator.** — I do not know what form of indicator was used by the North-Eastern Railway, but a very common form is one driven by a belt from one of the axles of the van, and indicating directly on a dial the speed at which the vehicle is moving. A glance at a planimeter would tell more than pages of description. Take a pair of compasses, and lay them horizontally on a sheet of paper. Hold one end fixed, and cause the other point to move along a straight line and back again. Watch the motion of the joint whilst doing this, and you will see that had there been a wheel attached to it it would have revolved a certain number of times in one direction as you went along the line, and again the same number of times the reverse way as you came back, ending exactly where it started. Now repeat the operation, but follow the outline of a rectangle (or other figure) this time, and you will find that the algebraical sum of the back and forth movements of the wheel will not now be zero. This difference bears a definite relation to the area of the figure traced by the moving point. Given mechanism for registering the sum of the wheel's revolutions and certain constants pertaining to the instrument, and you can at once calculate the area of any figure traced by the moving point. W. J. G. F.

[96590.]—**Motor Bike.**—Take my advice and don't make one; they are utter rotten. Plenty advertised far cheaper than you could buy even parts. Useless in the wet. If you want a few details, however, I may be able to give you some information. 1. Gauge for tube: use one gauge heavier all round than roadster, except where strain is most felt—viz., on front forks; these must be at least three gauges heavier, and head tube stiffened by inserting two D-shaped liners, flat to flat, half-way up, the whole well brazed together; 26in. wheels, tandem tires twice canvas lined; fabric is no good at all for motor work. You can buy sets of $\frac{3}{4}$H.P. motor parts, advertisement in this paper, which are suitable; $2\frac{3}{8}$in. diam. cylinder by $2\frac{3}{4}$in. stroke; fly-wheels must be used. Other theory seems feasible, but does not work well in practice, unless you hang a flywheel about 18in. diam. on hub. Use helical gear (spiral) if you like to transmit power, ratio six to 1. Ball bearings are not satisfactory; have seen them well tried with no apparent compensating advantages; with best make of cups, wear into a series of minute dents, and give trouble with adjustment, being slack when cold and too tight when engine warms up. Roughly speaking, with a $1\frac{1}{4}$H.P. motor, a pint of spirit will carry you nine miles—depends on weather, though; lubricating oil Price's. Two tablespoonfuls will carry you 20 miles with electric ignition, 15 with lamp. You must, however, guard against leaks. Take as a model for bike, machine described by "Derwent." You can place motor either on front or between cranks where it will not go without a wide tread; or make motor take the place of lower main tube, in which case it would be diagonal; or, for variety, place it upright over back mud-guard; right place I think is where back bridge is on machine; back frame being suitably lengthened, motor vertical "Dions" are placed thus. I am too busy to give further particulars. MONTY.

[96592.]—**Phonograph.**—"Amateur Mechanic"

should find no difficulty in constructing the Gillett phonograph, providing he has the necessary tools, and gets the thread on the main shaft cut by some experienced firm, as stated; but I should advise him to have it cut with 100 threads to the inch, instead of 80, so as to be able to reproduce from the Edison standard records. If he will advertise his address I will inform him how to make the phonograph more up-to-date. F. F.

[96594.]—**Ship's Tonnage.**—Gross expresses total cubical interior space of vessel. Net expresses the cubical space available for freight-carrying. There are several kinds:—(1) Displacement. (2) Register, gross and net. (3) Freight. (4) Builder's. (5) Yacht. (1) For war-ships. (2) For commercial purposes. (3) and (4) are different rules for carrying power. (5) is for classification of pleasure craft. Tonnage equals L × B × D × a decimal factor ÷ 100. Decimal factor for ship's sailing, ·7; steam vessels and clippers (two-decked), ·65; ditto three-decked, ·68; yachts above 60 tons, ·5; small vessels, ·45. Gross tonnage under deck equals L × B × D × decimal factor ÷ 100 decimal factor; passenger steamer's high speeds and sailing ships, ·6 to ·65; passenger and cargo steamers, ·7 to ·72; cargo steamers and oil-tank steamers, ·72 to ·8. L = inside length on upper deck from plank at bow to plank at stern; B = inside main breadth from ceiling to ceiling at timber strake. Horse-power: Nominal is commercial term used by makers to denote only size of engine, without regard to the actual power it will exert. Nominal H.P. of non-condensing engines. Rule: Multiply square of diam. of cylinder in inches by 7, and ÷ 80. Nominal H.P. of condensing engines. Rule: Multiply square of diam. of cylinder in inches by 7, and divide by 120. Actual H.P. Rule: Multiply area of cylinder in square inches by the average effective mean pressure of steam in pounds per square inch, minus 3lb. per square inch for friction, and by speed of piston in feet per minute. Product = number of foot-pounds per minute engine will raise. Divide this by 33,000, and the quotient = actual H.P. of engine. Brake H.P. is power of engine measured by friction brake or dynamometer. It equals effective H.P. or indicated H.P. minus power absorbed by its own friction. H.P. equals unit of power for driving machinery, is power required to do work at 33,000 units of work per minute, or to lift 33,000lb. 1ft. high per minute, or 550lb. at 1ft. per minute, or 55lb. at 10ft. per second. REGENT'S PARK.

[96595.]—**Foreign Books.**—Foreign booksellers like Williams and Norgate, Dulau and Co., H. Grevel and Co., O. E. Junson and Son, Putnam and Son, or even B. T. Batsford (all London) may be worth trying. REGENT'S PARK.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

GREAT BRITAIN is the largest customer of the United States for mineral oil, taking last year 242,265,563 gallons, as against 155,203,222 sent to Germany, 53,398,115 to Japan, 44,523,552 to China, and 360,431,316 to various European countries.

ACCORDING to an American contemporary, a machine-tool manufacturer in the United States is now making magnetic chucks, which are designed to do away with belting, strapping, or otherwise fastening down work by the usual methods, which require considerable time. The mechanism consists of an electro-magnet made in box form, completely inclosing an electric coil. A switch is provided to manipulate the current, which may be taken from the shop-lighting circuit, and any of the chucks can be connected in place of a lamp.

QUERIES.

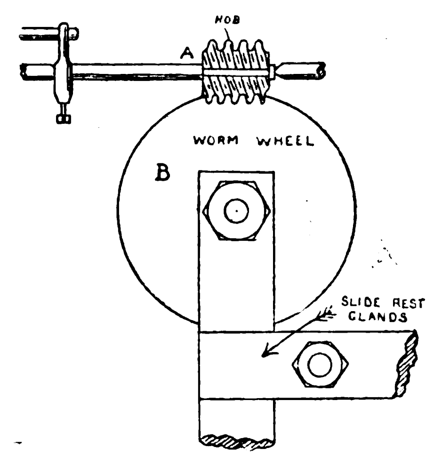
[96598.]—**Self-Sustaining Gear for Hoist.**—Will any reader kindly suggest a simple self-sustaining gear for a 6cwt. hoist? The hoist is belt-driven and lowers by its own weight, but has a tendency to run away down when weight is put on, unless someone is holding on brake at bottom.—C. C.

[96599.]—**Cutting by Circular Saws.**—In the shop in which I am employed we have two circular saws for cutting girders, &c. Both of these run so as to cut upwards on the work. While some of the men say this is the correct way, others say that they should cut downwards on the work. Perhaps some of your correspondents could say which is correct.—APPRENTICE.

[96600.]—**Astronomical Signs.**—Will anyone tell me where the symbols of the signs of the Zodiac and the symbols that are used for the planets first originated?—F. C. LAMBERT.

[96601.]—**Telescope.**—I live near the seashore—indeed, almost at sea-level. Nevertheless, without climbing a hill at all, I can see land across the sea quite distinctly on a clear evening without the aid of a glass of any kind. Those hills I see are, I know, 60 to 70 miles distant, and what I would like to be told is the number and probable cost of lenses required to make a telescope which would show a house or like object on those hills as distinctly as one can see a house a mile distant with the naked eye.—J. SMITH.

[96602.]—**Cutting a Wormwheel.**—May I trouble my fellow-turners for some help on the following? I had a wormwheel to cut 50 teeth ¼in. pitch. I calculated diameter of pitch circle, which came to 3·98. Then I added height of tooth each side of P. circle, which brought outside diameter to 4·14in. The way it was to be done



was with a hob driven between centres of lathe as shown (A). The wheel was to revolve on a bar fastened in slide-rest, as shown (B). While hob revolved the wheel was worked gradually in. After a few revolutions we counted the teeth, which turned out to be 57. Also the teeth were being cut away altogether. Can the wheels be done in this manner? I can't see how, although they have been done, I am told. My difficulty is: Suppose the worm was calculated to give 50 teeth on P. line. The hob was started on outside diameter of wheel, therefore there must be over 50 teeth owing to increased diameter, 2 by ·3 P., which is twice the height of tooth outside P. circle diam. Now, as the hob was worked into the bottom of teeth the diameter got less than P. circle; therefore the number of teeth would be less, which would be impossible. I should like a little help out of the difficulty. Is there any fault with hob if they are done this way?—TURNER.

[96603.]—**Gas Blowpipe.**—Will any reader kindly give sketch with dimensions of a powerful gas blowpipe, suitable for brazing, &c.? Any hints on making will oblige.—GAS.

[96604.]—**Transformer.**—I thank correspondents for information on charging accumulators, and would now like to know whether the current from the dynamo (6v., 50amp.) could be adapted by means of a transformer to light a few 20v. 16c.p. lamps. If so, please give data for constructing transformer.—E. A. W.

[96605.]—**Gas Pressure.**—Will some reader kindly explain simple rule for working out the following? Suppose a cylinder having a capacity of 5c.ft. with a pressure of 100lb. to square inch should burst, say, inside another having 20c.ft. capacity, what pressure should I have in the larger cylinder?—GAS PRESSURE.

[96606.]—**Defective Battery.**—I have bought a wet battery with porous and zinc in it. I have also a bell, but have not connected it as yet. I have connected wire on to hook on zinc, and one on to terminal on top of porous, and also connected a separate wire to both of them, and held them, and touched one and both with tip of tongue, but can't get a least bit of current. There are two small holes on top of porous one, with a little plug on, and the other nothing but the small hole in it. I should be extremely glad if any readers of ENGLISH MECHANIC would give me some information about it, and whether it is the fault of battery. Perhaps I have connected the wires wrong?—W. H. M.

[96607.]—**Mummy Wheat.**—As the story concerning the germination of wheat from ancient Egyptian sepulchres has again turned up (see p. 59), one would like to know whether any proof of this has recently been obtained. De Candolle observes: "No grain taken from an ancient Egyptian sarcophagus and sown by horticulturists has ever been known to germinate," and mentions that even American maize is palmed off on suspecting tourists as grain from the tombs.—J. DORMER.

[96608.]—**Electric Clock.**—I have, as an amateur, constructed an electric clock, and although the clock itself goes and keeps time admirably, I have been unable up to the present to find a suitable battery that will supply current for a sufficient period of time. The best results up to now have been from a Fuller battery, which succeeded for a month only, and then gave out. It is a pendulum clock, and has only three contacts per minute, each only a fraction of a second in duration. Do you think a battery of Leclanché cells (say six) would be sufficiently lasting? Or what would you advise? It takes about six volts to drive it.—E. A. LESLIE.

[96609.]—**Ether.**—Can any reader give me references to articles or publications dealing with the most recent experiments in ether waves, and the apparatus used?—CURIOUS.

[96610.]—**Motor Roller.**—Would any of "ours" kindly say what would be the probable cost of a set of accumulators, giving dimensions, &c., to work a 3H.P. electric motor, intended to propel a 30cwt. roller for a cricket green? Any information with regard to any special type of motor, and cost of same, also of battery, would last for an eight-hours' run at a time, will oblige. I prefer an electric motor, as we have every facility for charging cells.—IDEAL.

[96611.]—**To Mr. Bottone.**—Would Mr. Bottone greatly oblige by informing me what quantity and size of wire I would require to wind a voltmeter to register ten volts?—VOLTMETER.

[96612.]—**Silver Wash.**—Can some readers instruct me in the making of silver washes?—J. M. W.

[96613.]—**Motor Waggon.**—Can someone kindly say the power of oil-motor required to propel nearly one ton at walking pace? And what make might be recommended for cheapness and durability?—C.

[96614.]—**Charging Pocket Accumulator with Small Dynamo.**—I have a small pocket accumulator, and also a 15c.p. dynamo, with H armature. I don't know the ampèrage or voltage; but it is wound with B.W.G. 24 wire. Can I charge the accumulator with this? And if so, how?—CARLIOL.

[96615.]—**Brown Boot Polish.**—In the reply by "Regent's Park" on p. 44 to question 96427 on p. 584 he mentions a chemical called phosphin, which I have not been able to get at some of the largest chemists in Manchester, as they do not know it. I should be much obliged if someone could give me a recipe for a good brown boot polish.—STELLA.

[96616.]—**To Mr. Bottone.**—I have a small motor (or dynamo), with an armature (plain drum), 1¾in. outside when wound by 1¾in. long, laminated, commutator four segments. The iron of field-magnets is ⅜in. thick, cast, and winding space 1¾in. by 1¼in. by ¾in. deep. I have wound fields with five layers of No. 18 B.W.G. I intend making a series motor of it; but want to know what wire to use for armature, which is 1in. before winding. (2) Could you oblige me with a table of copper wires from 10 to 30 B.W.G., giving resistances per 100 yards, and weights of ditto also if possible, areas of wires and turns per inch? (3) What is a three-phase current?—H. Æ. S.

[96617.]—**Telephone.**—I shall be greatly obliged if anyone can tell me the best arrangement for following purpose. I wish to fit up a table telephone for use of a partially deaf person, and have a Hunning's cone transmitter (with carbon grain) and a double-pole watch receiver. The line will only be four yards of wire; but I want to get the maximum sound from the receiver under these conditions. If a secondary circuit is necessary for the purpose, please say gauge and lengths of wire suitable.—C. ROBERTS.

[96618.]—**Reducing Temperature.**—What ought I to do for the above? Size of room 12ft. by 9ft. by 8ft. high? Average heat this summer 65° Fahr. Wish to keep it to 50° Fahr. Window is blocked up; moisture no object.—F. S.

[96619.]—**Electric Organ.**—I have a two-manual American organ, and also a small pipe organ, and I wish to connect them by electricity, so that by depressing the keys of the American organ, the corresponding ones of the pipe organ will also be depressed. How can this be done? If this is not practical, could I, by an electric arrangement, add a few pipe stops to the American organ? If so, how could I obtain instructions? Is there any work published dealing with electric-organ building?—J. S. Z.

[96620.]—**Acids for Etching and Engraving.**—Will any reader kindly tell me the acid and chemicals, &c., for eating into by etching or engraving deeply into the following metals: steel (knives, scissors, &c.), brass (articles and letter-plates), nickel goods, as money-boxes, &c.? I have used nitric acid, but with very variable and uncertain success. While it acts on brass deeply, it only faintly touches steel and nickel, and not deeply, as I require, and gets underneath the beeswax and effervesces it, causing a black blotch, thus spoiling the article. I suppose the heat of the acid melts the wax? I should like acid to eat into the above metals without discolouring the lettering; also in each metal to burn the lettering a chemical black or other colouring that shows up well and neatly. What tools do I require for ordinary writing and for small block lettering?—ETCHING ACID.

[96621.]—**Warts.**—Would some reader please tell me of a way to cure warts? I have unsuccessfully tried nitric acid, acetic acid, lunar caustic, &c. What is the cause of them? I have got a lot, and some more are coming.—CICERO.

[96622.]—**Motor-Cycle.**—Will the writer of the articles now appearing kindly give sizes and quantities of wire for the induction-coil?—W. A. J.

[96623.]—**Steamer.**—*Empress Queen*, paddle, plying between Liverpool and Douglas. Please give horse-power, tonnage, speed, and passenger capacity of above?—A. G.

[96624.]—**Etching or Engraving Ground.**—Will any correspondent kindly tell me the best, most reliable, and durable etching or engraving ground to use for etching or engraving names, monograms, mottoes, quotations, &c., on metal articles, such as knife blades, scissors and on brass and cheap nickel goods, such

nickel money-boxes, &c.? Some ground superior to beeswax, and that does not tear, chip, or flake when using the etching needle, &c., and that will withstand the acid. As an amateur I have tried beeswax by heating the metal and rubbing on the wax, but find it unreliable; the plate of wax after etching is easily damaged by touch or contact, and when applying the acid (nitric) the acid somehow causes the wax to effervesce and gets underneath it, and burns only a black blotch, spoiling the article. Have only got a burnt blotch on no end of articles after hours and hours of most tedious scratching with a needle much words and lettering.—ETCHING GROUND.

[96625.]—**Brass Coating for Iron Wire.**—I would like to know how to put a brass coating on to iron wire the same way as they coat copper wire. I do not want a lacquer, nor to be run through melted brass. It will have to be run through a liquid, but I should like something to take the place of copperas to throw a brass colour on it.—S. BATEMAN.

[96626.]—**Steamer's Tonnage.**—Please explain terms, net tonnage, gross tonnage, tons, burdens, and displacement. How is it taken, and how much of the ship taken into account? Steamer is said to be 500 horse nominal and 3,000 effective. How is this worked on, and what do steamers work on for the East, say?—ALGOODE.

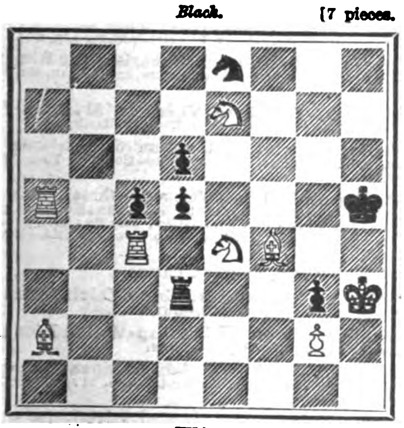
[96627.]—**Foreign Currency.**—As I expect to go to South America, please explain the working, &c., of exchange, for I see Rio is 7d. and Buenos Ayres 120. If I send out £200 and remit home, which I presume must be in dollars, 200 dollars (pesos) from Buenos Ayres and 10,000 reis ex Rio. Kindly explain working of exchange, as I should like to know before I go.—ALGOODE.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1691.—By C. A. GILBERG.

Black. [7 pieces.



White. [8 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Sept. 18.*)

Solution of PROBLEM No. 1689.—By H. VON DUBEN.

Key-move, P-R 4.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1689.—Correct solution has been received from A. Tupman, Quizco, Hampstead Heathen, Rev. Dr. Quilter, T. Clark, Richard Inwards, F. B. (Oldham).

No. 1688.—In reference to this really clever problem, Hampstead Heathen wrote last week: "It was hours before that key-move struck me." Whin Hurst, on the other hand, writes: "She (the Oracle) guessed the puzzler in a few minutes." A. T. writes: "Cannot find any solution, and, being away from home, have only just received the next number, in which I expected to find some correction. Shall await next issue with interest."

Gilding of Glass or Porcelain.—To gild glass or porcelain, instead of the ordinary mixture, a solution of gold chloride in oil of turpentine or lavender oil, to which a little bismuth nitrate and chrome soap have been added, is employed. The following mixture is said to give good results:—Lavender oil, 900 grammes; gold chloride, 100 grammes; bismuth sub-nitrate, 5 grammes; chrome soap, 50 grammes. After the application allow the mass to dry, and bake the articles in the muffle furnace. The gilt portions show a nice gloss, without any subsequent treatment.—*Neueste Erfindungen und Erfahrungen.*

Magnesium Flashlights.—A possibly useful addition to the data governing the composition of these mixtures may be found in a paper recently read before the Paris Academy of Sciences by M. H. le Chatelier, who finds a greater certainty of combustion in mixtures of the nitrate of ammonia class by making a special crystal from a solution containing potassium chlorate and ammonium nitrate. By modifying the temperature of the solution and the proportions of the ingredients, he was able to produce a crystal of definite and constant proportions; it contained five per cent. of the chlorate.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Sept. 6, and unacknowledged elsewhere:—

A. DRYSDALE.—J. M. W., Trin. Coll. Oxon.—J. Hope.—Eric.—W. H.—Sufferer.—Perplexed.—R. S. Edwards.—Rewobole.—Metal Turner.—Sawrey.—Mousetrap.—Quex.—G. F. C.—Searle.—Erin.—W. G. Black.

A. DRYSDALE.—We cannot tell you. Probably the editor replied in the paper or inserted your query. It is, as a rule, utterly impossible for editors to reply privately to non-readers of their papers.

CHAS. TURNER.—We cannot undertake to advise as to infringement of patents.

WATTY.—You can add some coal-oil to it, which will keep it "sticky" for a long time.

A READER.—Must go through a course of instruction in an assayer's laboratory; no other way, unless sufficient information can be picked up at one of the technical schools where practical work is possible. Read up the manuals on the subject.

THOMOND.—It is simply ground up with water; but a liquid Indian ink is sold at all the shops which sell artists' materials.

W. T. W.—Mr. Robertson's articles on the "Practical Construction of the Organ" commenced in No. 1597, and concluded in No. 1664. They were published in a revised form by Sampson, Low, Marston, and Co., in a volume of text and another of plates.

J. T.—Please see Hints to Correspondents, No. 4.

F. C. LAMBERT.—From any bookseller, if you mention the chart required. Proctor's Star Atlas (Longmans) may suit, or that by Peck, "The Constellations and How to Find Them," published by Archibald and Peck, Edinburgh; or "The Observer's Atlas of the Heavens," by William Peck, published by Gall and Inglis, Paternoster-square, London, E.C.

J. SMITH.—You should procure some field-glasses on trial, or if you wish to make a telescope suitable you should refer to the indices. If from the sea-level you can see the "horizon" 70 miles distant, you do not want a telescope. What is the height of the hills you can see? Many directions for making terrestrial telescopes have been published. We think Lancaster and Son, Birmingham, publish a cheap pamphlet on How to Make a Telescope. Many of the back numbers are out of print, so the query is inserted—modified.

H. PAYNE.—Unvulcanised rubber means the pure rubber, which can be dissolved in chloroform, sulphuric ether, mineral naphtha, &c.; but "curing" means mixing it with sulphur or a preparation of sulphur—sometimes sulphide of antimony. For nursing bottles the rubber should be as pure as possible. See the indices under Indiarubber, Caoutchouc, &c. The rubber should be dissolved by some agent which will evaporate and leave it practically pure after the solvent has evaporated. The best solvent, from the commercial point of view, is caoutchoucin.

N. D. P.—See back volumes for picture-frame making and cutting mounts. The frames are worked up in a mitring box, and the joints are glued and nailed. A series of articles on Picture-frame Making commenced in No. 1739 and concluded in No. 1744.

BORLASE.—There are several recipes in back volumes; but the usual method is to make the tinplate hot and brush it over with a solution of hydrochloric acid, then cooling quickly.

WM. H. O'BRIEN.—It is not easy to get into an electrical engineering works as an improver, for most employers require a premium. If you can see Southam's "Electrical Engineering as a Profession and How to Enter It," published by Whittaker and Co., you will find much useful information.

WILLIAM MORRIS.—Probably it would be "something new to the scientific world," but we cannot form an opinion until we have some data. Apparently it is a general cosmic law, but it is not quite clear what is meant.

A SUBSCRIBER'S SON.—If you mean a pharmaceutical chemist, apply to the secretary of the Pharmaceutical Society for information about the examinations. If you mean "chemist" in the proper meaning of the term, you must study at one of the schools, and, as a preliminary, pass the examinations of the Science and Art Department.

J. H.—If you are thinking of going in for the Whitworth Scholarship, better procure the special manual, which can be had from "all booksellers," or from John Heywood, Manchester; or from Eyre and Spottiswoode, East Harding-street, E.C. It is No. 455, "Prospectus of the Whitworth Scholarships," &c., post free 7d., and is the official publication.

OLD SUB.—It is a matter of personal taste. Some people mount them with a glass front, and do not use any frame.

SUPERFLUOUS.—We simply meant that all available information had been given—many times. There is really *no* permanent cure for superfluous hair but electrolysis. The ordinary depilatories depend more or less on lime or other similar ingredients, the effect of which is temporary and mostly injurious. The best remedy is shaving.

H. WOOTTON.—There has been a great deal of matter about compensation of watches, &c., in the back volumes; but if you cannot see them, you could call in at the Horological Institute, Northampton-square, E.C. (a short walk for you), and no doubt the authorities would allow you to see their library.

W. S. W.—We utterly fail to understand your question or sketch. What machine is it, and what do you mean by the "force"? If you will explain yourself, and conform to our rules by sending a comprehensible sketch on a separate paper, we will see if we can make it out, or if some of our readers can.

IN TYPE.—C. P. Pilgrim.

AN armour test was recently made at the Indian Head (U.S.A.) proving grounds of a 5½in. plate, representing 700 tons of the casemate and belt armour of the battleship Alabama. Two 6in. projectiles failed to pierce the plate, the greatest depression being 3½in., and there were no cracks.

A NEW means of effecting ignition and combustion in internal-combustion engines has recently been invented, according to the *Electrical Engineer*. The method consists in compressing the combustible charge to a degree below that at which it attains its ignition temperature, and then forcing into it another combustible having a lower ignition temperature, such that it becomes ignited by the heat of the compressed charge, and thereby effects its combustion. Again, by varying the manner of the introduction, and the proportion of the charge introduced, the combustion of the working charge can be correspondingly varied.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any o the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Wanted 5in. or 6in. Screwcutting Lathe, in exchange for ½ Horizontal Oil or GAS-ENGINE, two flywheels, 4in. centre gap Lathe, Slide-rest, and small Dynamo.—M., 5, Norfolk-terrace, Faraday-road, Wimbledon.

Second-hand **Gas-Engine**, 1H.P., good order, complete, £15, or terms arranged.—Below.

Lathes, also Parts, new and second-hand. Machined Castings. Exchanges effected.—GANNON BROS., Lathe Makers, Chelmsford.

Engine and Boiler (stationary), about 1H.P. Exchange for Chuck, Stocks, Dies. £9.—SEAL, Castelnau, Barnes, Surrey.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of **Screws, Bolts**, and NUTS for model work, drawn to actual size, sent on receipt of stamp.—MORRIS COHEN, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—MORRIS COHEN, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—CLEGG, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 3d.—JARRATT, Queen-street, Leicester.

Carving. — Brass, Iron, Burnt Wood, Bamboo, Leather, Fretwork, and Picture Framing. Catalogue free.—HARBERS, Settle, Yorks.

Inventions Protected, £2 inclusive. Designs registered, 30s.—BROMHEAD and Co., Registered Patent Agents, 33, Cannon-street, London. Established 25 years. Send for list.

Sidereal Time Indicator, invaluable to all users of equatorials, with complete directions, 21s. post free.—Below.

Astro-Photographic Apparatus, does really good work, 15s. post free.—HORNE and THORNTHWAITE, 416, Strand, London.

Rubber Outer Covers, average 16oz., Para rubber 8s. each.—FRANKLANDS.

Rubber Outer Covers, 3s. 6d. each, 36s. per dozen. —FRANKLANDS.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—FRANKLANDS.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—FRANKLANDS.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight., 2s. each.; 21s. per dozen.—FRANKLANDS.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 2s. 6d. each.—FRANKLANDS.

Detachable Outer Covers, licensed, 12s. 6d. each. —FRANKLANDS.

Saddles.—A clearing line in ladies' and gents' saddles, 2s. 6d. each, 24s. per dozen.—FRANKLANDS.

Inflators, 18in., 1s. 6d. each, 15s. dozen. — FRANKLANDS.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 5s. per dozen.—FRANKLANDS.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—FRANKLANDS.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—FRANKLANDS.

Spanners, nickel, usual price, 13s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—FRANKLANDS.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—FRANKLANDS, Astley Gate, Blackburn.

Books.—All out-of-print books speedily procured, any subject. State wants.—BAKER'S GREAT BOOKSHOP, Birmingham.

Photography.—Watkins' Actinometer makes exposure certain, new watch shape, 3s. 6d.—FIELDS, 142, Suffolk-street, Birmingham.

50,000 Choicest Microscopical Objects.—Bargains. Catalogues free. Microscopes, cabinets. Collections purchased.—SUTER, 10, Highweek-road, Tottenham.

Rubber Outer Covers, 3s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—PEMBERTON.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—PEMBERTON.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—PEMBERTON.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—PEMBERTON and Co., 1, Cardwell-place, Blackburn.

Acetylene. — Send for particulars of the patent "Incanto" Generators, Purifiers, Burners, Carbide, &c.—THORN and HODDLE, 1, Tothill-street, Westminster. Works, Harris-street, Camberwell.

Inventions Protected and Sold. Inventors assisted. Advice free.—ELT and Co., 43 Southampton-buildings, Holborn, London.

Practical Milling in the Lathe has been reduced to its simplest possible form by our Simplicity Milling Attachment. Send stamp for list to—SMART and Co., Erith, Kent.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—BUTLER BROS., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—BUTLER.

"Spesco" Belting Syrup, prevents slipping and keeps belts in good condition. 1lb. sample tin, post free, one shilling. SPESCO Ltd., Suffolk-place, Bermondsey, London.

AND WORLD OF SCIENCE AND ART.
FRIDAY, SEPTEMBER 15, 1899.

MOTOR CYCLES.—XVII.

HAVING described the construction of both motor and tricycle, a chapter on its use and how to remedy breakdowns will be acceptable. Before proceeding with this, I may inform my readers that, in response to inquiries, I have made arrangements whereby they can obtain all the necessary castings and forgings without the trouble and expense of pattern-making. The Inflexible Works Co., of Wolverhampton, have made the patterns under my supervision, and can supply castings promptly.

Before attempting to use the motor-tricycle, I would advise learning to steer an ordinary tricycle. Riders of safety bicycles will find less difficulty than non-cyclists, though even to them the steering will come awkward at first. Having fully mastered this matter, the first thing will be to see that the petrol tank is filled. The spirit used should not exceed ·680° specific gravity, to test which a densimeter is indispensable. These can be obtained for a few shillings from most any dealer in motor-cycles. Next make sure the accumulator is well charged, and all connections clean and secure. There should be two cells in series in the accumulator, these giving 4 volts on the average. When these points are satisfactorily arranged, go all round the machine and make sure that all nuts are tight and every part lubricated. Sufficient of the best gas-engine oil must be poured into the crank-case to allow the crank-discs to dip into it to a depth of about ½in. or ¾in. Next open the compression cock, and squirt into the cylinder a few drops of paraffin to free the rings from any oil which has gummed. This should be done every time a start is made, if the machine has been standing above an hour or so, and also on putting the machine away for the night. Now put the plug into the plug-switch on the underside of top tube, and mount into the saddle. The float and carburetter being charged with spirit to the correct depth, turn on the handle-bar switch and pedal the machine smartly forward. The proper position for the air and gas levers for starting will be found by experiment. As a guide for the commencement, I should shut off all the air, leaving the gas full open. See that the sparking gear is in such a position that the spark takes place when the piston is at the top of the compression stroke, or even slightly later. If, after pedalling a few revolutions, no firing of the charge takes place in the cylinder, gradually modify the mixture of air and gas until the motor fires once or twice, when the compression-cock should be suddenly shut. Now the motor should run evenly; but if not, move the sparking-gear lever gradually backwards till it fires evenly and without any knock in the motor, helping by pedalling if required. Any knock in the engine indicates that the sparking takes place too early, driving the piston and connecting-rod down while the crank-pin is still on the up-stroke. This, besides straining the various parts, is liable to stop the engine entirely. To obtain the maximum power the mixture, must be regulated as well as the ignition. When the motor is running at its highest speed, which may reach to over two thousand revolutions per minute, the passage of the spark across the platinum points of the ignition plug takes place during the compression stroke, though the complete ignition of the charge is much later. The reason for this is that the air and gas mixture takes an appreciable time to become thoroughly ignited and to reach its maximum pressure. Now, while this burning of the charge is proceeding, the piston is travelling very rapidly; hence to insure the greatest pressure being reached at the top of the stroke, we must commence to fire the charge while the piston is still travelling upwards. The faster the speed of engine, the earlier must contact be made. On the other hand, if we advance the sparking, the motor will increase its speed up to a certain point, depending on the resistance it has to overcome. If the motor is *fully* loaded and the sparking be advanced, it is ten to one it will stop, since its speed cannot increase. Therefore, when ascending hills the "advance," or "lead," of the spark must be decreased according to the speed of the engine. With a little practice, it is astonishing what a variety of speeds can be obtained by the proper manipulation of the ignition gear. With tube ignition the motor can only fire correctly at one definite speed, any variation of which results in either miss- or back-fires.

To stop, one or both brakes should be applied, and the handle-bar switch turned off at the same time. Unless it is required to stop very suddenly, apply the band-brake on the back axle only, and that not too quickly. In emergencies only should both brakes be used. Even if the switch be not turned off, the brakes will still stop the machine. To descend a long hill, if fairly steep, I usually content myself by cutting off the current by means of the switch, and rely on the compression of the motor to check the speed. Should it become excessive, the brakes can be used in addition. When you have stopped, if you leave the machine, *take the plug out of the switch and pocket it*, then if any one, with sufficient knowledge to do so, tries to play a practical joke by running the battery down, the laugh will be all on your side.

Breakdowns and Remedies.

In spite of the most careful attention, motors, in common with all other kinds of machinery, are liable to temporary derangement. I will endeavour to point out the most likely of these, and suggest their remedies.

When the motor is new, a certain amount of metal is worn off the working faces, which mixes with the oil in crank-case and causes further wear to take place. Therefore, for the first few days, the lubricant in the crank-case should be changed every twenty or thirty miles. After about three or four hundred miles have been run, it will suffice to change this oil every fifty miles. But however well the moving parts have worn to place, fifty miles should be the maximum run with one charge of lubricant. If the cylinder head is not well cleared of particles of core sand, trouble may ensue from these particles getting into the bearings, or between the piston and cylinder, where they will cut like a file. Too much oil in the crank chamber results both in smoke and smell from the exhaust, caused by the excess of oil burning.

Many breakdowns can be traced to loose nuts and bolts or defective connections in the electric currents. Other causes are defects in (1) the accumulator, (2) the wiring, (3) contacts on motor, (4) the sparking plug, (5) the spirit. I have placed these in the order of their probability. Taking them in the above order, the accumulators should be tested both with volt and ampère meters. The former should never register lower than 1·9 volt per cell. When this is reached they require recharging. When newly charged, the ampère meter should show from five to six ampères. Two and a half or three ampères will give a spark of sufficient heat; but when the current reaches this low point the cells should be recharged, failing which only very short rides should be taken. The wiring is easily repaired, should the circuits be broken anywhere, and calls for no special remarks. The contacts of the ignition gear on the motor will require looking to occasionally to make sure they are screwed up tightly, and that the cam really makes metallic contact with both springs. In the sparking plug is an insulating tube of porcelain. This sometimes gets cracked, in which case either the insulation breaks down, or the compression of the motor is lost. A simple and at the same time effective test for this is to use a mixture of soap and water, smearing a little over the plug, when on turning the motor bubbles will be caused if there is any leakage. When on the road this would not be convenient; therefore, put in a new plug—a spare one should always be carried. It may happen in damp or cold weather that the spirit will not vaporise. In this case it will generally be found that the petrol in use has a greater density than ·680°. Remedy: Use fresh spirit. In testing the density of the spirit due allowance should be made for temperature. In hot weather spirit of ·700° density can be used; in cold ·680° should not be exceeded. These densities are taken at 15° centigrade. Each degree in temperature makes a difference of 0·8° in the density of the spirit. Another important point is that fresh spirit will not *mix* with old. It will float on the top. It will be found that after running a little while the vibration of the machine will shake up the petrol, and cause more gas to be given off. The mixture will then be too rich, hence it will be necessary to open the air-holes in the mixture-cock.

To test the contact-breaker on motor, proceed thus: Take off the ignition-gear cover, and, having removed the wire from the insulated terminal of the sparking plug, turn on the handle-bar switch, and put in the plug of plug-switch. With one hand bring the end of the wire taken from sparking plug to within about ⅟₁₆in. of any metal part of the motor; with the other hand press the two contact springs down on to the cam. At each contact a stream of good "fat" sparks should spring across from wire to motor. If no spark results, either the contacts are dirty or the circuit is broken somewhere. In either case the remedy is obvious. Should the spark be short and "thin," look to the charging of the battery. While making the above test take care not to hold the bare wire, but the insulation. Neglect of this precaution will give a nasty shock. It may be that the vibrating contact-breaker on the coil is at fault. This should be adjusted till a good hot spark is produced. See that the platinum contacts on the vibrating contact-breaker on coil are kept clean and free from roughness.

Take out the plug and see if a spark is produced across its points when the secondary of the coil is coupled up, one wire to the insulated terminal, the other to the metal body of plug. If the porcelain is cracked or loose, use a new plug. The sparking points on plug may be either too far apart or too close. They should be about one millimètre apart. The porcelain insulator should be clean and free from soot, as this may cause sufficient short circuiting to prevent a good spark being obtained. If the wiring is all perfect, the batteries well charged, the sparking plug and contacts in good order, and the contact-breaker on valve gear sleeve all right, the fault is most likely in the handle-bar switch. To test this, remove a part of the insulation from the wires which lead to the handle-bar switch, bridge them across with a piece of wire, and again press the contact-springs on to the cam. If the spark is produced, the machine can still be ridden by using the brakes for stopping, and the plug switch for cutting off the current. In the event of all the petrol being used up, and no more obtainable, common benzine may be tried; but I am not certain that it will work with the form of carburetter described—in fact, it is very doubtful.

Breakdowns caused through breakage of

any part are outside the province of these articles; but if the mishap is to the motor, its transmission gear, or the carburetter, the driving pinion can be removed and the machine pedalled along as an ordinary tricycle, though, of course, much heavier.

To summarise the foregoing. To start, charge the battery, fill the petrol tank, and see that the float and carburetter get their supply. Mount, open the compression cock, put in plug of switch, turn on handle-bar switch, put sparking gear in position, pedal forward, and close compression cock after first two or three explosions. To stop, switch off current, and put on one or both brakes.

It is proposed to supplement these articles with a description of a detachable fore-carriage, which will convert the single tricycle into a tandem quadricycle at will.

ERRATUM:—In Fig. 55, the thickness of the boss for brake fulcrum-pin is given as $\frac{1}{2}$in. each side of centre. It should be $\frac{1}{2}$in. on the side adjacent to brake-drum, $\frac{1}{4}$in. on the other.

MILLWRIGHT'S WORK.—IX.

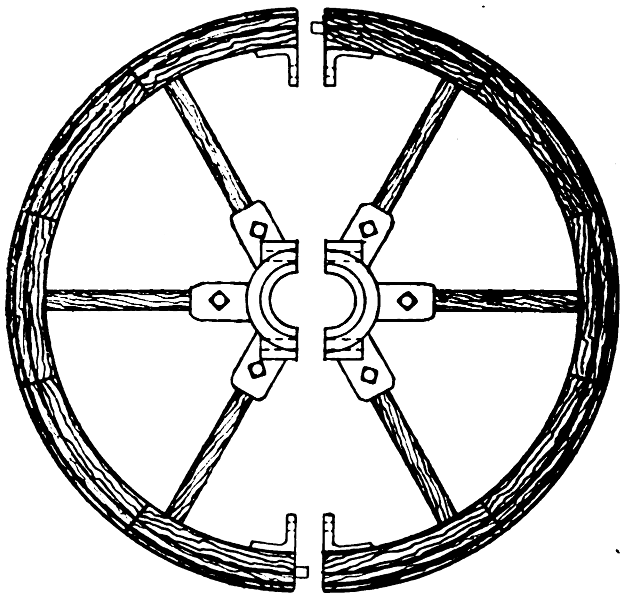

FIG. 57.

THE fast and loose pulleys used on counter-shafts have given occasion for a great variety in design. These are generally of cast iron. The pulleys shown in Fig. 52, by the Chain Belt Engineering Co., of Derby, are of a composite character, the idea being to combine lightness with rigidity. The arms and boss are of cast iron. The ends of the arms are expanded

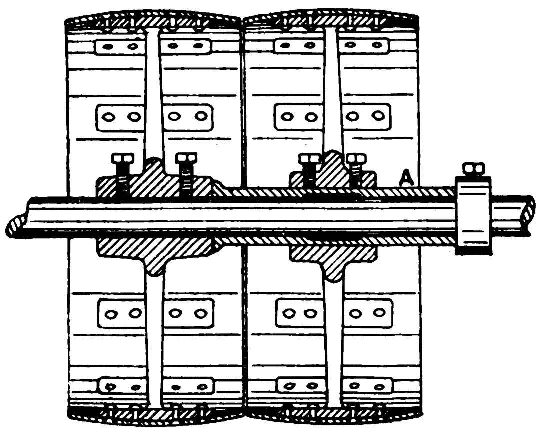

FIG. 52.

to form flanges, to which the wrought-iron rim is riveted. The figure also shows the method adopted in the fitting of fast and loose pulleys when over 30in. diameter. The latter is bored to receive an exceptionally long sleeve, A, which reduces the friction per unit on the shaft, and in

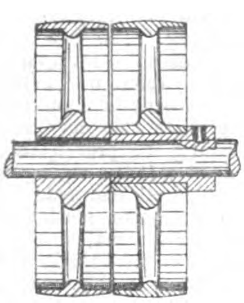

FIG. 53.

the bore, and prolongs its life. When worn too, it can be readily replaced, without throwing away the pulley.

The practise of bushing the loose pulley in some way to prevent wear on the shaft is now common, though only adopted in recent years. Fig. 53 illustrates a simple method, the bush being fitted with a collar with a flush set-screw, so serving the double purpose of bush and loose collar.

Fig. 54 shows the loose pulley of Trier Bros. A is a gunmetal bush in halves, which fits the shaft, and is bored to suit the pulley. It is gripped in place by a patent split collar B, which thus serves a double purpose.

Smith and Grace make a loose pulley with a self-oiling bush, Figs. 55 and 56. It consists of a cylinder, flanged at the ends to fit the bore of the pulley tightly. The oil is contained within the flanges, and runs through perforations in the bush on to the shaft. When the pulley is at rest the oil lies on the bottom of the chamber. It requires to be changed once only in several months, through the boss.

Few, in the absence of experience, would have thought timber a suitable material for pulleys; yet pulleys of this class, when of moderate dimensions, have grown in favour, and are used to a very large extent. They are constructed by the pattern-maker's method of building up of segments, well glued and nailed. Maple is the material used—a hard, close-grained wood, the surface of which takes a high polish. There is little risk of the pulleys going out of truth to an extent which would seriously impair their efficiency, while their lightness is a distinct recommendation, insomuch as they diminish the strain on shafts and bearings by comparison with pulleys constructed of iron.

Different methods of constructing and fitting wood pulleys are made use of. In the smaller sizes they are solid—that is, they are built up in solid bodies without arms, the smallest consisting of two halves united with screws and nuts. The nuts are imbedded in, and secured with brimstone, and the screws are turned in by their slotted heads. The joint-faces of the halves are made with irregular waved faces, in order to interlock with one another, and prevent overlapping of the edges. Another solid pulley is bolted in halves, and the heads of the bolts are incased by blocks screwed above them, giving a flush face for the driving-belt. In another type the rim is built in concentric segments, but the pulley is plated with a central web of wood, flanked with an iron centre boss, key grooved, and fitted with a set-screw. This is used for high-speed driving, such as that of dynamos, the

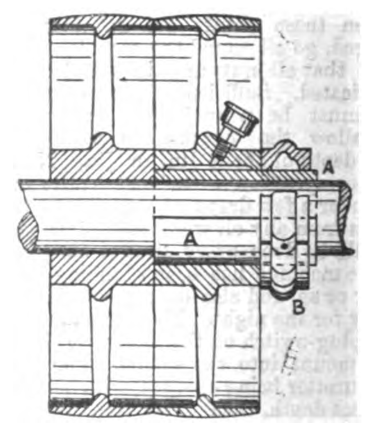

FIG. 54.

solid plate offering no resistance to the air, as arms would do. The largest class of pulley is made with straight arms, which abut at the boss, and are let into the rim, glued, and keyed. The boss is fitted with a divided iron centre, turned, bored, and key-seated. The two halves of the

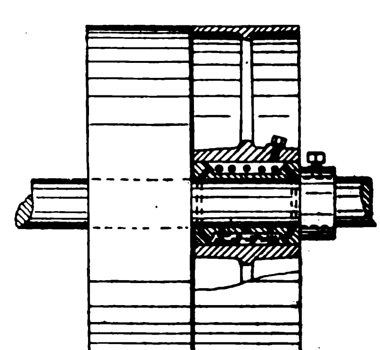

FIG. 55.

pulley are clamped with clips within the rim, and with plates next the boss. All these pulleys are fitted with bushings of wood.

The system of bushing pulleys is adopted in the case of wood pulleys. The Jones Foundry and Machine Co., of Chicago, bore all their pulleys to two sizes only; all below 24in. in diameter are bored for a 3in. shaft, all over

24in. to 3½in. Bushings of wood are then supplied to suit any or all sizes of shafts. These bushings are clamped by the tightening of the bolts next the pulley-boss. They are made of hard wood in the following way: First the stuff is dried in air, then bored approximately, removing the bulk of the material, and the stuff dried thoroughly in a kiln; then each bush is counterbored to size of shaft, put on a mandrel, and turned to fit the pulley-bore, then cut longitudinally in halves.

Caldwell and Son, of Chicago, make composite pulleys with interchangeable iron bushings, Fig. 57. The rims and arms are of wood, the arms being of circular section; the bosses are of iron, socketed to receive the arms, secured with set-screws. All these pulleys are split, dispensing with keys.

The methods by which pulleys are secured to their shafts are more varied than formerly. The time-honoured method of keying by driving a taper key in a cast-iron boss is not the best

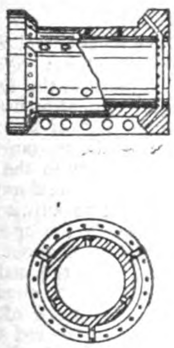

FIG. 56.

possible. It has been responsible for the splitting of many pulley bosses, and it requires a key-groove in the shaft at least twice the length of the key. Keys are expensive to fit; but there is no other method in the case of a large solid cast-iron pulleys. The smaller pulleys are held with set-screws, and also with saddle keys; but these are not suitable for large pulleys.

Large split pulleys grip the shaft by the tightening up of the boss bolts, and this is sufficient for those of moderate dimensions. In the case of those of larger size, sunk feather keys are better than taper ones. They require no special fitting, and the key-groove is only as long as the key itself.

Pulleys of small diameters are often fixed with a set-screw instead of with a key. Some firms supply an interchangeable series in which the same pulley can be used as fast or loose—the fast with a set-screw, the second with a lubricator. They are exactly alike in all respects, and the arrangement is suitable for sizes up to 24in. diameter.

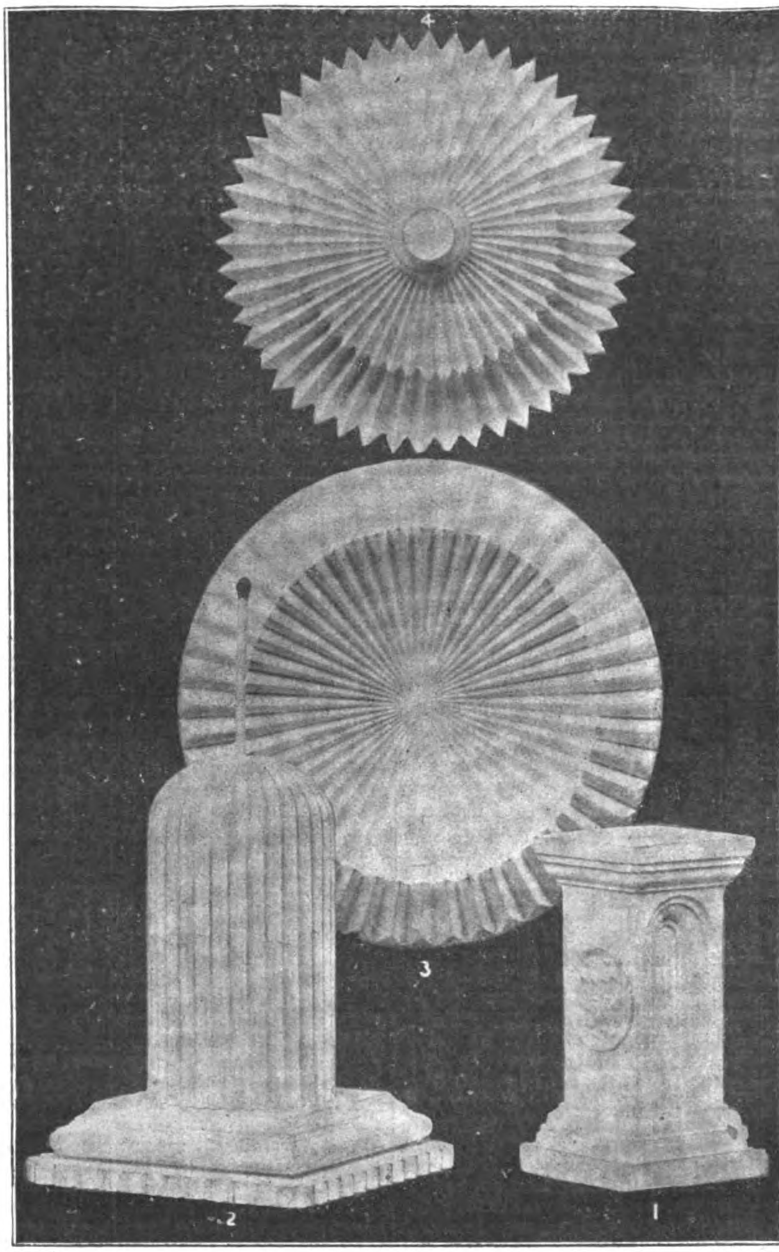
J. H.

ORNAMENTAL TURNING.—XXVII.

By J. H. EVANS.

IN pursuance of studies of the capabilities of the dome or spherical chuck, which in my last I treated as far as necessary what I may term the primary stages of its manipulation—upon again reading through the matter, I find I can yet give a few more useful hints; but as I was going well within the limits of space I generally occupy, I thought it well to shut off steam at that point. The subject, however, is, I may say, an exhaustive one, and I hope deserving of all that can be said as to its merits, and that which may lead to its further development.

My last details were applicable to the chuck when used for the shaping and decorating of polygonal figures, and upon the accuracy in the formation of such solid forms entirely depends their success and beauty. This is only acquired by the most careful attention as to the adjustment of the dome-chuck. Any error in its vertical adjustment will be fatal to good work, and will cause the mitring of the corner to be at an angle to, and not parallel with, the axis of the form. This may not, however, be visible upon the original flat facets, but will become very apparent upon the horizontal surfaces of the mouldings and fillets, which will not be in one plane round the four sides of the square. Should this defect arise, it may be assumed that there is some im-



perfection in the vertical adjustment of the chuck. The error once detected is easily remedied by a slight movement of the worm-wheel of the tangent-screw, to move the mandrel a small degree in whichever direction it is required to correct the error. The work is then cut over again, and the accurate meeting of the surfaces and mitring of the corners will certify that at last all is satisfactory. It is not a difficult job, but is one that is well worth the attention the above remarks direct.

We will now proceed to a few examples of finished work, bearing out fully the result of various settings and adjustments already referred to. As the subject of squares and polygonal figures is now uppermost in our minds, Fig. 1 will form a good subject in furtherance of our object. To reproduce this example, the dome chuck is accurately adjusted as before described. The work is turned to the bare circular form, then placed in the chuck while in the before-mentioned position. The slide-rest is set transversely across the lathe-bed, and the eccentric cutter with a round-nose tool is then placed in the slide-rest. The radius of the tool is extended to just cover the space between the base and the cornice, the work being adjusted by the main screw of the chuck to bring the centre of the face opposite the axis of the lathe mandrel. The cutter is then, while revolving at high speed, passed over the surface to be cut by the screw of the slide-rest, the penetration being adjusted to bring the corners up sharp and square, maintaining the limit of the square as large as the cylindrical form will allow.

If the height of the pedestal is greater than can be covered by one cut, then the vertical movement of the work, to above and below the centre, must be brought into play, and the process of cutting be repeated. The first face reduced satisfactorily, it only remains to treat the three remaining sides of the square in precisely the same way.

The base and capital must now claim our attention: these must be first reduced to the corresponding form. As each of these represents a much less depth, the radius of the tool may be reduced to complete the surface remaining to be cut, while the work is raised or lowered to bring that part in contact with the tool. The two thus shaped are ready to receive the mouldings. This may be done either with separate tools, in the eccentric cutter, a moulding, the figure in one tool, or a moulding drill. If the latter be employed, the work must be brought to a closer contact for the necessary cut required to complete the figure by again elevating or depressing the arm of the chuck; but when the eccentric cutter is used this may be avoided by increased radius being given to the tool.

The base and cornice of Fig. 1, now under our notice, were both cut at the same time, and to effect this I used a self-contained moulding tool, extending the radius to cover both, carefully passing the same over the whole surface of both top and bottom in one cut. This is one point, in my opinion, greatly in favour of this particular kind of tool. There are times, of course, when a series of two or three separate tools are preferred; but there are times when you would certainly wish to do as much as possible at one cut, and this is one of them, more especially as it performs the work with every satisfaction, and in considerably less time. Mouldings of this type

are also cut with the same tool, revolving horizontally in the universal cutter set in this position, the radius being adjusted to suit the material and its various proportions.

In some cases this may, perhaps, be deemed preferable, the frame of the instrument, from its construction, being less likely to come in contact with other projections on the work, which may be in close proximity to that under treatment.

Reference to the illustration will clearly demonstrate the necessity for the accuracy of the mitres, to which I have repeatedly alluded, as it will show at once that if these are not correct the whole work will be worthless.

If it is desired to further decorate facets of the figure, each one may be so embellished with a variety of patterns, the eccentric cutter becoming an important factor for the purpose. The centre of one square (*vide* Fig. 1), it will be seen, has a plain eccentric pattern cut. To effect this, the tool in the eccentric cutter is set to the centre of its own axis, while the centre of the square is adjusted by the vertical movement to agree with it. The index is placed in the 96 circle of division, or the same may, with even more safety, be still under the guidance of the segment apparatus. I say more safely, because this is one of the instances which entails an entire revolution of the dome chuck, and the weight being so much on one side, when in the horizontal position, it is likely to force the index from the hole. This, however, is a matter that, with care, can be avoided, and with the bridle on the depth screw, the left hand is free to regard this and prevent a slip. The tool is now extended to a radius of $\frac{3}{10}$, and the slide-rest moved forward $\frac{1}{10}$, then cut at every twelve holes, using a double-angle tool.

A second side of this figure, it will be observed, has been cut as a widely different example, and here is an instance of the variety of different effects obtained in numerous ways by the same tool. The identical tool was here employed by which the base and cornice were worked, and yet its present purpose is distinct in itself.

The eccentricity of the cutter is reduced to cover the width of the recess it is desired to cut, and it may be well to again remind one that by adjusting the edge of the tool to the exact axis of the spindle, it forms a drill, and can be used for this purpose.

Having so set the tool to the desired radius, the dome chuck is set to the horizontal position, and having previously devoted the time and care to its vertical adjustment, it only remains to carefully move the worm-wheel of the segment apparatus forty-five whole turns of its tangent screw, the slide-rest remaining a fixture as before. The fluting stops are fixed one on each side of the slide to arrest the longitudinal progress of the tool at the desired point, the cutter is revolved at a high speed, and traversed regularly through the necessary length.

If it is desired to cut out and decorate a panel with square terminals, the sides must be cut by the vertical transverse of the slide of the chuck, while the work must be raised and lowered for the purpose of effecting the same shape at each end.

This description of panelling may also be cut with a number of consecutive cuts seriatim, and this is a kind of decoration where the divisions on the micrometer on the main screw of the chuck are of much service. For instance, if the ends have been serrated, say at every one or two turns of the slide-rest screw, the sides must be cut in equal proportions; therefore the vertical movement must coincide with that of the slide-rest; the length and breadth of the panel or recess being arranged to receive so many cuts each way.

For works of extensive size, it is always preferable to build up the subject of separate pieces, more especially when the material used is ivory, as the reduction of the circular form to a square pedestal involves a considerable loss.

We pass now to Fig. 2, which illustrates a further and distinct mode of decoration, and, as will be readily seen, consists of a reeded spherical top, with the same figure carried through the diameter of the cylindrical body. As shown, the example represents a matchbox, being a suitable object for our purpose, and at the same time useful and decorative. The box is first turned out inside, and the lid fitted; it is then turned to the desired proportion externally while on the mandrel nose; it is afterwards mounted on the dome chuck. The dome is then adjusted by the slide of the chuck, and the reed on this part first cut, the slide-rest being set parallel with the lathe-bed; the universal cutter being the most suitable instrument to employ. This when placed in the slide-rest is set over to 90°, so that it will revolve in the vertical plane, and a double quarter-hollow tool, as shown in my last used. This must be accurately set to the test point presumably left on the dome.

The depth of penetration required must be decided by the two trial cuts, and when all is thus set, it will require three turns of the tangent screw for each successive cut. When the dome has been thus treated throughout its diameter, the slide-rest must be turned to a right angle, and fixed transversly across the lathe-bed. The dome chuck is then brought to the horizontal position by forty-five turns of the tangent screw of segment apparatus, and the universal cutter turned to zero to bring it to the position in which it revolves horizontally, the same tool being still employed.

We now have to adjust the required depth of penetration very carefully to coincide with that of the serrations on the dome at the diametrical line. This is not a difficult matter by any means; but still it requires considerable care and attention. The moulding at the base has been worked up in a somewhat different way—that is, by cutters varying in form and the manner of their application. The manipulation of the chuck also receives fresh treatment. The square is first roughly shaped, and with so much material to remove a saw may be very usefully employed. Having removed the four sides, and faced over the surface on one side, a hole about $\frac{3}{4}$in. in diameter is turned out at the centre. By this it is fitted to a short plug or chuck which for convenience must be less in diameter than the sides of the square. When it is fitted to the chuck, it is better to fix it with a little thin glue to insure its being retained in the required position. It is then reduced to the necessary thickness.

The next thing will be to mount it on the dome chuck. Again set to the vertical position, the slide-rest remaining as set at right angles to the bed, the eccentric cutter being used in exactly the same manner as detailed. Having cut the four sides square, the tool is exchanged for one with a square end $\frac{1}{10}$ wide, the work lowered in order that the facets may be further recessed, leaving the lower extremity $\frac{1}{10}$ deep. It is then still further lowered, and recessed at the upper part to remove the superfluous material, in order that the bead-tool shall not have more to do than absolutely necessary.

The universal cutter again succeeds the eccentric, and with a bead-tool of the required dimensions the base of the moulding is shaped, and again the work is depressed, and with a round-nose tool the concave curve is cut, a square fillet intervening between it and the base.

By reference to the illustration it will be seen that the extreme base is reeded. To effect this the chuck still remains in the vertical position, while the universal cutter is again set over to 90° to cut vertically, and the tool exchanged for a double quarter-hollow tool. The point is then set accurately to the centre of the square by the lateral traverse of the slide-rest, the micrometer being set to zero. The work is then spaced out to receive so many cuts on each side of the centre. When thus set, the tool is revolved at a high rate of speed, and the work passed up and down through the space to be cut by the main screw of the dome chuck. To admit of this, the nut at the back of the right-angle arm is slightly released, just sufficient to allow it to work with the necessary freedom. In the example before us there are twelve consecutive cuts in each square, the depth being determined as before mentioned, and the tool moved laterally $\frac{1}{10}$, or two turns of the slide-rest screw.

We come now to Fig. 3, and this demonstrates the use of the dome chuck as used for the decoration of concave curves, and this of very increased dimensions. Here, again, the bare form is first reduced by hand turning to the approximate proportions, it is then mounted on the dome chuck, which is adjusted so that it will allow the tool to follow the curve contained in the figure. This is a case in which the chuck that holds the work must be as shallow as possible, so that the axis of the work may be placed as far as possible from the centre of the lathe axis away from the operator. The chuck must now be fixed in the horizontal position, and the slide-rest set parallel with the lathe-bed, while the universal cutter is again set to revolve vertically with the double quarter-hollow tool, which must be extended to a radius of $\frac{1}{10}$ so that the full depth of the curve may be cut without the frame reaching the edge of the work.

The point of the tool must be accurately set by the movement of the slide-rest to agree with the test-point left for the purpose when the work is prepared by hand. The arm of the chuck is then moved along the body of the chuck until the tool will pass as nearly as possible over the desired curve, the depth again ascertained in the usual way by two trial cuts; the worm-wheel of the chuck is then moved two turns for each succeeding cut. The partial rotation of the mandrel is arrested at the centre by one of the segment-pins. When arranging this, the radius of the tool must be considered, as it should just pass out at the centre; therefore, when this is duly allowed for, the chuck will not assume the exact horizontal position each time the tool reaches the centre. The tool passing out at the diameter, it is not necessary to employ the second stop-pin, except to prevent the chuck swinging round if the hand should be inadvertently released.

To reproduce Fig. 4 and our final example, the work is as usual reduced to the required form approximately, then mounted on the dome chuck when in the vertical plane; the slide-rest still parallel with the lathe-bed, the universal cutter being again the instrument to use; but we now have a double-angle tool of 50° extended to a radius of $\frac{5}{10}$. Here again we must be careful in setting the same precisely to the centre of the test-point, and equal consideration must be devoted to the depth; to adjust the latter, the cutter is moved towards the operator, and the cutter placed over the concave curve. The work is then moved up to it by the main screw of the dome chuck, and, when deep enough, the tool is withdrawn by the guide-screw of the top slide. The worm-wheel is then moved two turns, and the second cut made. The depth is so arranged that the edges are quite sharp; each successive cut is then made by the movement of the top slide of slide-rest; the horizontal arms being rigidly fixed when all the adjustments are made.

The periphery is cut by the tool being moved on the required distance, the nut of arm released, and the work passed up and down by the screw of chuck. The points form a very effective terminal to the incision on the concave curve.

The chuck which holds the work is now placed in a deep transfer to extend the convex curve further from the axis of the lathe, and, as the illustration shows, the particular shape requires to be a portion of a large circle. The screw of the chuck is adjusted to the required position, the same tool being set to follow accurately over the curve, thus carrying out the same figure entirely over the necessary form. Many very beautiful specimens are to be produced by varying the profile of the tool used.

I have now, I hope, given all the information necessary to the manipulation and development of the valuable adjunct to the ornamental turner's outfit. I propose to follow with particulars of the spherical slide-rest, it being somewhat allied to the subject we have just completed, in so much as the results are similar, with considerably increased varieties.

THE torpedo-boat destroyer *Viper* was launched last week by Messrs. Hawthorn, Leslie, and Co. She is fitted with Parsons' steam turbines, and is guaranteed to steam 31 knots. She will be ready for speed trials in six weeks.

THE sleepers used on the Chicago and Eastern Illinois Railway are now being treated with preservatives, the zinc-tannin process being used. The wood is first steamed, and the sap extracted by a vacuum, after which three solutions are injected into the wood in succession. The first of these is chloride of zinc, which is followed by a second of gelatine, and by one of tannin. The latter do not penetrate deeply, but form a sort of artificial leather in the outer layers of the wood, and thus prevent the zinc washing out. For satisfactory results it is important that the temperature during the steaming process should not exceed 260° Fahr.

THE BRITISH ASSOCIATION.

PRESIDENT'S ADDRESS.

THE sixty-ninth annual meeting of the British Association for the Advancement of Science was commenced at Dover on Sept. 13, when Prof. Sir Michael Foster, K.C.B., Sec.R.S., delivered the address as President. Commencing with a few words of sympathetic regret at the loss of so many great men, who had in bygone years served as Presidents or otherwise, and particularly Sir Douglas Galton, Sir Michael said:—

Still older than the Association is this nineteenth century, now swiftly drawing to its close. Though the century itself has yet some sixteen months to run, this is the last meeting of the British Association which will use the numbers eighteen hundred to mark its date.

The eyes of the young look ever forward; they take little heed of the short though ever-lengthening fragment of life which lies behind them; they are wholly bent on that which is to come. The eyes of the aged turn wistfully again and again to the past; as the old glide down the inevitable slope their present becomes a living over again the life which has gone before, and the future takes on the shape of a brief lengthening of the past. May I this evening venture to give rein to the impulses of advancing years? May I, at this last meeting of the Association in the eighteen hundreds, dare to dwell for awhile upon the past, and to call to mind a few of the changes which have taken place in the world since those autumn days in which men were saying to each other that the last of the seventeen hundreds was drawing towards its end?

Dover in the year of our Lord seventeen hundred and ninety-nine was in many ways unlike the Dover of to-day. On moonless nights men groped their way in its narrow streets by the help of swinging lanterns and smoky torches, for no lamps lit the ways. By day the light of the sun struggled into the houses through narrow panes of blurred glass. Though the town then, as now, was one of the chief portals to and from the countries beyond the seas, the means of travel were scanty and dear, available for the most part to the rich alone, and, for all, beset with discomfort and risk. Slow and uncertain was the carriage of goods, and the news of the world outside came to the town—though it, from its position, learnt more than most towns—tardily, fitfully, and often falsely. The people of Dover sat then much in dimness, if not in darkness, and lived in large measure on themselves. They who study the phenomena of living beings tell us that light is the greatest stimulus of life, and that the fulness of the life of a being or of any of its members may be measured by the variety, the swiftness, and the certainty of the means by which it is in touch with its surroundings. Judged from this standpoint, life at Dover, then, as indeed elsewhere, must have fallen far short of the life of to-day.

The same study of living beings, however, teaches us that while from one point of view the environment seems to mould the organism, from another point the organism seems to be master of its environment. Going behind the change of circumstances, we may raise the question, the old question, Was life in its essence worth more then than now?

Has there Been a Real Advance?

Let me at once relieve your minds by saying that I propose to leave this question in the main unanswered. It may be, or it may not be, that man's grasp of the beautiful and of the good, if not looser, is not firmer than it was a hundred years ago. It may be, or it may not be, that man is no nearer to absolute truth, to seeing things as they really are, than he was then. I will merely ask you to consider with me for a few minutes how far, and in what ways, man's laying hold of that aspect of, or part of, truth which we call natural knowledge, or sometimes science, differed in 1799 from what it is to-day, and whether that change must not be accounted a real advance, a real improvement in man?

I do not propose to weary you by what in my hands would be the rash effort of attempting a survey of all the scientific results of the 19th century. It will be enough if for a little while I dwell on some few of the salient features distinguishing the way in which we nowadays look upon, and during the coming week shall speak of, the works of Nature around us—though those works themselves, save for the slight shifting involved in a secular change, remain exactly the same—from the way in which they were looked upon and might have been spoken of at a gathering of philosophers at Dover in 1799. And I ask your leave to do so. In

The Philosophy of the Ancients,

earth, fire, air, and water were called the "elements." It was thought, and rightly thought, that a knowledge of them and of their attributes was a necessary basis of a knowledge of the ways of Nature. Translated into modern language, a knowledge of these "elements" of old means a knowledge of the composition of the atmosphere, of water, and of all the other things which we call matter, as well as a knowledge of the general properties of gases, liquids, and solids, and of the nature and effects of combustion. Of all these things our knowledge to-day is large and exact, and, though ever enlarging, in some respects complete. When did that knowledge begin to become exact?

To-day the children in our schools know that the air which wraps round the globe is not a single thing, but is made up of two things, oxygen and nitrogen (some may already know that there is at least a third thing, argon) mingled together. They know, again, that water is not a single thing, but the product of two things, oxygen and hydrogen, joined together. They know that when the air makes the fire burn and gives the animal life, it is the oxygen in it which does the work. They know that all around them things are undergoing that union with oxygen which we call oxidation, and that oxidation is the ordinary source of heat and light. Let me ask you to picture to yourselves what confusion there would be to-morrow, not only in the discussions at the sectional meetings of our Association, but in the world at large, if it should happen that in the coming night some destroying touch should wither up certain tender structures in all our brains, and wipe out from our memories all traces of the ideas which cluster in our minds around the verbal tokens oxygen and oxidation. How could any of us, not the so-called man of science alone, but even the man of business and the man of pleasure, go about his ways lacking those ideas? Yet those ideas were in 1799 lacking to all but a few.

Although in the third quarter of the 17th century the light of truth about oxidation and combustion had flashed out in the writings of John Mayow, it came as a flash only, and died away as soon as it had come. For the rest of that century, and for the greater part of the next, philosophers stumbled about in darkness, misled for the most of the time by the phantom conception which they called

Phlogiston.

It was not until the end of the third quarter of the 18th century that the new light, which has burned steadily ever since, lit up the minds of the men of science. The light came at nearly the same time from England and from France. Rounding off the sharp corners of controversy, and joining, as we may fitly do to-day, the two countries as twin bearers of a common crown, we may say that we owe the truth to Cavendish, to Lavoisier, and Priestley. If it was Priestley who was the first to demonstrate the existence of what we now call oxygen, it is to Lavoisier we owe the true conception of the nature of oxidation and the clear exposition of the full meaning of Priestley's discovery, while the knowledge of the composition of water, the necessary complement of the knowledge of oxygen, came to us through Cavendish and, we may perhaps add, through Watt.

The date of Priestley's discovery of oxygen is 1774. Lavoisier's classic memoir "On the Nature of the Principle which Enters into Combination with Metals during Calcination," appeared in 1775, and Cavendish's paper on the composition of water did not see the light until 1784.

During the last quarter of the 18th century this new idea of oxygen and oxidation was struggling into existence. How new was the idea is illustrated by the fact that Lavoisier himself at first spoke of that which he was afterwards—namely, in 1778, led to call oxygen, the name by which it has since been known, as "the principle which enters into combination." What difficulties its acceptance met with is illustrated by the fact that Priestley himself refused to the end of his life to grasp the true bearings of the discovery which he had made. In the year 1799 the knowledge of oxygen, of the nature of water and of air, and indeed the true conception of chemical composition and chemical change, was hardly more than beginning to be, and the century had to pass wholly away before the next great chemical idea, which we know by the name of the Atomic Theory of John Dalton, was made known. We have only to read the scientific literature of the time to recognise that a truth which is now not only woven as a master-thread into all our scientific conceptions, but even enters largely into the every-day talk and thoughts of educated people, was a hundred years ago struggling into existence among the philosophers themselves. It was all but absolutely unknown to the world outside those select few.

Electricity.

If there be one word of science which is writ large on the life of the present time, it is the word "electricity." It is, I take it, writ larger than any other word. The knowledge which it denotes has carried its practical results far and wide into our daily life, while the theoretical conceptions which it signifies pierce deep into the nature of things. We are to-day proud, and justly proud, both of the material triumphs and of the intellectual gains which it has brought us, and we are full of even larger hopes of it in the future.

At what time did this bright child of the nineteenth century have its birth? He who listened to the small group of philosophers of Dover, who in 1799 might have discoursed of natural knowledge, would perhaps have heard much of electric machines, of electric sparks, of the electric fluid, and even of positive and negative electricity; for frictional electricity had long been known and even carefully studied. Probably one or more of the group, dwelling on the observations which Galvani, an Italian, had made known some twenty years before, developed views on the connection of electricity with the phenomena of living bodies. Possibly one of them was exciting the rest by telling how he had just heard that a professor at Pavia, one Volta, had discovered that electricity could be produced not only by rubbing together particular bodies, but by the simple contact of two metals, and had thereby explained Galvani's remarkable results. For, indeed, as we shall hear from Prof. Fleming, it was in that very year, 1799, that electricity as we now know it took its birth. It was then that Volta brought to light the apparently simple truths out of which so much has sprung. The world, it is true, had to wait for yet some twenty years before both the practical and the theoretic worth of Volta's discovery became truly pregnant, under the fertilising influence of another discovery. The loadstone and magnetic virtues had, like the electrifying power of rubbed amber, long been an old story. But, save for the compass, not much had come from it. And even Volta's discovery might have long remained relatively barren had it been left to itself. When, however, in 1819, Oersted made known his remarkable observations on the relations of electricity to magnetism, he made the contact needed for the flow of a new current of ideas. And it is, perhaps, not too much to say that those ideas, developing during the years of the rest of the century with an ever-accelerating swiftness, have wholly changed man's material relations to the circumstances of life, and, at the same time, carried him far in his knowledge of the nature of things.

Geology.

Of all the various branches of science, none, perhaps, is to-day, none for these many years past, has been so well known to, even if not understanded by, most people as that of geology. Its practical lessons have brought wealth to many; its fairy tales have brought delight to more; and round it hovers the charm of danger, for the conclusions to which it leads touch on the nature of man's beginning.

In 1799, the science of geology, as we now know it, was struggling into birth. There had been from of old cosmogonies, theories as to how the world had taken shape out of primæval chaos. In that fresh spirit which marked the zealous search after natural knowledge pursued in the middle and latter part of the seventeenth century, the brilliant Stenson in Italy, and Hooke in our own country, had laid hold of some of the problems presented by fossil remains, and Woodward, with others, had laboured in the same field. In the eighteenth century, especially in its latter half, men's minds were busy about the physical agencies determining or modifying the features of the earth's crust; water and fire, subsidence from a primæval ocean and transformation by outbursts of the central heat, Neptune and Pluto, were being appealed to, by Werner on the one hand, and by Desmarest on the other, in explanation of the earth's phenomena. The way was being prepared, theories and views were abundant, and many sound observations had been made; and yet the science of geology, properly so-called, the exact and proved knowledge of the successive phases of the world's life, may be said to date from the closing years of the eighteenth century.

In 1783, James Hutton put forward in a brief memoir his "Theory of the Earth," which, in 1795, two years before his death, he expanded into a book; but his ideas failed to lay hold of men's minds until the century had passed away, when, in 1802, they found an able expositor in John Playfair. The very same year that Hutton published his theory, Cuvier came to Paris and almost forthwith began, with Brongniart, his immortal researches into the fossils of Paris and its neighbourhood. And four years later, in the year 1799 itself, William Smith's tabular list of strata and fossils saw the light. It is, I believe, not too much to say that out of these geology, as we now know it, sprang. It was thus in the closing years of the eighteenth century that was begun the work which the nineteenth century has carried forward to such great results. But at that time only the select few had grasped the truth, and even they only the beginning of it. Outside a narrow circle the thoughts, even of the educated, about the history of the globe were bounded by the story of the Deluge—though the story was often told in a strange fashion—or were guided by fantastic views of the plastic forces of a sportive nature.

Biology.

In another branch of science, in that which deals

with the problems presented by living beings, the thoughts of men in 1799 were also very different from the thoughts of men to-day. It is a very old quest, the quest after the knowlege of the nature of living beings, one of the earliest on which man set out; for it promised to lead him to a knowledge of himself, a promise which perhaps is still before us, but the fulfilment of which is as yet far off. As time has gone on, the pursuit of natural knowledge has seemed to lead man away from himself into the furthermost parts of the universe, and into secret workings of nature in which he appears to be of little or no account; and his knowledge of the nature of living things, and so of his own nature, has advanced slowly, waiting till the progress of other branches of natural knowledge can bring it aid. Yet in the past hundred years the biologic sciences, as we now call them, have marched rapidly onward.

We may look upon a living body as a machine doing work in accordance with certain laws, and may seek to trace out the working of the inner wheels, how these raise up the lifeless dust into living matter, and let the living matter fall away again into dust, giving out movement and heat. Or we may look upon the individual life as a link in a long chain joining something which went before to something about to come, a chain whose beginning lies hid in the farthest past, and may seek to know the ties which bind one life to another. As we call up to view the long series of living forms, living now or flitting like shadows on the screen of the past, we may strive to lay hold of the influences which fashion the garment of life. Whether the problems of life are looked upon from the one point of view or the other, we to-day, not biologists only, but all of us, have gained a knowledge hidden even from the philosophers a hundred years ago.

Of the problems presented by the living body viewed as a machine, some may be spoken of as mechanical, others as physical, and yet others as chemical, while some are, apparently at least, none of these. In the 17th century William Harvey, laying hold of the central mechanism of the blood stream, opened up a path of inquiry which his own age and the century which followed trod with marked success. The knowledge of the mechanics of the animal and of the plant advanced apace; but the physical and chemical problems had yet to wait. The eighteenth century, it is true, had its physics and its chemistry; but, in relation at least to the problems of the living being, a chemistry which knew not oxygen and a physics which knew not the electricity of chemical action were of little avail. The philosopher of 1799, when he discussed the functions of the animal or of the plant involving chemical changes, was fain for the most part, as were his predecessors in the century before, to have recourse to such vague terms as "fermentation" and the like; to-day our treatises on physiology are largely made up of precise and exact expositions of the play of physical agencies and chemical bodies in the living organism. He made use of the words "vital force" or "vital principle" not as an occasional, but as a common, explanation of the phenomena of the living body. During the present century, especially during its latter half, the idea embodied in those words has been driven away from one seat after another; if we use it now when we are dealing with the chemical and physical events of life we use it with reluctance, as a *deus ex machinâ* to be appealed to only when everything else had failed.

Some of the Problems—

and those, perhaps, the chief problems—of the living body have to be solved neither by physical nor by chemical methods, but by methods of their own. Such are the problems of the nervous system. In respect to these the men of 1799 were on the threshold of a pregnant discovery. During the latter part of the present century, and especially during its last quarter, the analysis of the mysterious processes in the nervous system, and especially in the brain, which issue as feeling, thought, and the power to move, has been pushed forward with a success conspicuous in its practical, and full of promise in its theoretical, gains. That analysis may be briefly described as a following up of threads. We now know that what takes place along a tiny thread which we call a nerve-fibre differs from that which takes place along its fellow-threads; that differing nervous impulses travel along different nerve-fibres; and that nervous and psychical events are the outcome of the clashing of nervous impulses as they sweep along the closely-woven web of living threads of which the brain is made. We have learnt by experiment and by observation that the pattern of the web determines the play of the impulses, and we can already explain many of the obscure problems not only of nervous disease, but of nervous life, by an analysis which is a tracking out the devious and linked paths of nervous threads. The very beginning of this analysis was unknown in 1799. Men knew that nerves were the agents of feeling and of the movements of muscles; they had learnt much about what this part or that part of the brain could do; but they did not know that one nerve-fibre differed from another in the very essence of its work. It was just about the end of the past century, or the beginning of the present one, that an English surgeon began to ponder over a conception which, however, he did not make known until some years later, and which did not gain complete demonstration and full acceptance until still more years had passed away. It was in 1811, in a tiny pamphlet published privately, that Charles Bell put forward his "New Idea" that the nervous system was constructed on the principle that "the nerves are not single nerves possessing various powers, but bundles of different nerves, whose filaments are united for the convenience of distribution, but which are distinct in office as they are in origin from the brain." Our present knowledge of the nervous system is to a large extent only an exemplification and expansion of Charles Bell's "New Idea," and has its origin in that.

If we pass from the problems of the living organism viewed as a machine to those presented by the varied features of the different creatures who have lived or who still live on the earth, we at once call to mind that the middle years of the present century mark an epoch in biologic thought such as never came before, for it was then that Charles Darwin gave to the world the

Origin of Species.

That work, however, with all the far-reaching effects which it has had, could have had little or no effect, or, rather, could not have come into existence, had not the earlier half of the century been in travail preparing for its coming. For the germinal idea of Darwin appeals, as to witnesses, to the results of two lines of biologic investigation which were almost unknown to the men of the 18th century.

To one of these lines I have already referred. Darwin, as we know, appealed to the geological record; and we also know how that record, imperfect as it was then and imperfect as it must always remain, has since his time yielded the most striking proofs of at least one part of his general conception. In 1799 there was, as we have seen, no geological record at all.

Of the other line I must say a few words. To-day the merest beginner in biologic study, or even that exemplar of acquaintance without knowledge, the general reader, is aware that every living being, even man himself, begins its independent existence as a tiny ball, of which we can, even acknowledging to the full the limits of the optical analysis at our command, assert with confidence that in structure, using that word in its ordinary sense, it is in all cases absolutely simple. It is equally well known that the features of form which supply the characters of a grown-up living being, all the many and varied features of even the most complex organism, are reached as the goal of a road, at times a long road, of successive changes; that the life of every being, from the ovum to its full estate, is a series of shifting scenes, which come and go, sometimes changing abruptly, sometimes melting the one into the other, like dissolving views, all so ordained that often the final shape with which the creature seems to begin, or is said to begin, its life in the world is the outcome of many shapes, clothed with which it in turn has lived many lives before its seeming birth.

All or nearly all the exact knowledge of the laboured way in which each living creature puts on its proper shape and structure is the heritage of the present century. Although the way in which the chick is moulded in the egg was not wholly unknown even to the ancients, and in later years had been told, first in the sixteenth century by Fabricius, then in the seventeenth century in a more clear and striking manner by the great Italian naturalist Malpighi, the teaching thus offered had been neglected or misinterpreted. At the close of the eighteenth century the dominant view was that in the making of a creature out of the egg there was no putting on of wholly new parts, no epigenesis. It was taught that the entire creature lay hidden in the egg, hidden by reason of the very transparency of its substance, lay ready-made but folded up, as it were, and that the process of development within the egg or within the womb was a mere unfolding, a simple evolution. Nor did men shrink from accepting the logical outcome of such a view—namely, that within the unborn creature itself lay in like manner, hidden and folded up, its offspring also, and within that again its offspring in turn, after the fashion of a cluster of ivory balls carved by Chinese hands, one within the other. This was no fantastic view put forward by an imaginative dreamer; it was seriously held by sober men, even by men like the illustrious Haller, in spite of their recognising that as the chick grew in the egg some changes of form took place. Though so early as the middle of the eighteenth century Friedrich Caspar Wolff and, later on, others had strenuously opposed such a view, it held its own not only to the close of the century, but far on into the next. It was not until a quarter of the present century had been added to the past that Von Baer made known the results of researches which once and for all swept away the old view. He and others working after him made it clear that each individual puts on its final form and structure not by an unfolding of pre-existing hidden features; but by the formation of new parts through the continued differentiation of a primitively simple material. It was also made clear that the successive changes which the embryo undergoes in its progress from the ovum to maturity are the expression of morphologic laws, that the progress is one from the general to the special, and that the shifting scenes of embryonic life are hints and tokens of lives lived by ancestors in times long past.

If we wish to measure how far off in biologic thought the end of the last century stands, not only from the end but even from the middle of this one, we may imagine Darwin striving to write the "Origin of Species" in 1799. We may fancy him being told by philosophers explaining how one group of living beings differed from another group because all its members and all their ancestors came into existence at one stroke when the first-born progenitor of the race, within which all the rest were folded up, stood forth as the result of a creative act. We may fancy him listening to a debate between the philosopher who maintained that all the fossils strewn in the earth were the remains of animals or plants churned up in the turmoil of a violent universal flood, and dropped in their places as the waters went away, and him who argued that such were not really the "spoils of living creatures," but the products of some playful plastic power which out of the superabundance of its energy fashioned here and there the lifeless earth into forms which imitated, but only imitated, those of living things. Could he amid such surroundings by any flight of genius have beat his way to the conception for which his name will ever be known?

The Science of To-Day.

Here I may well turn away from the past. It is not my purpose, nor, as I have said, am I fitted, nor is this perhaps the place, to tell even in outline the tale of the work of science in the nineteenth century. I am content to have pointed out that the two great sciences of chemistry and geology took their birth, or at least began to stand alone, at the close of the last century, and have grown to be what we know them now within about a hundred years, and that the study of living beings has within the same time been so transformed as to be to-day something wholly different from what it was in 1799. And, indeed, to say more would be to repeat almost the same story about other things. If our present knowledge of electricity is essentially the child of the nineteenth century, so also is our present knowledge of many other branches of physics. And those most ancient forms of exact knowledge, the knowledge of numbers and of the heavens, whose beginning is lost in the remote past, have, with all other kinds of natural knowledge, moved onward during the whole of the hundred years with a speed which is ever increasing. I have said, I trust, enough to justify the statement that in respect to natural knowledge a great gulf lies between 1799 and 1899. That gulf, moreover, is a twofold one: not only has natural knowledge been increased, but men have run to and fro spreading it as they go. Not only have the few driven far back round the full circle of natural knowledge the dark clouds of the unknown which wrap us all about, but also the many walk in the zone of light thus increasingly gained. If it be true that the few to-day are, in respect to natural knowledge, far removed from the few of those days, it is also true that nearly all which the few alone knew then, and much which they did not know, has now become the common knowledge of the many.

What, however, I may venture to insist upon here is that the difference in respect to natural knowledge, whatever be the case with other differences between then and now, is undoubtedly a difference which means progress. The span between the science of that time and the science of to-day is beyond all question a great stride onwards.

We may say this, but we must say it without boasting. For the very story of the past which tells the triumphs of science bids the man of science put away from him all thought of vain-glory. And that by many tokens.

Whoever, working at any scientific problem, has occasion to study the inquiries into the same problem made by some fellow-worker in the years long gone by, comes away from that study humbled by one or other of two different thoughts. On the one hand, he may find, when he has translated the language of the past into the phraseology of to-day, how near was his forerunner of old to the conception which he thought, with pride, was all his own, not only so true but so new. On the other hand, if the ideas of the investigator of old, viewed in the light of modern knowledge, are found to be so wide of the mark as to seem absurd, the smile which begins to play upon the lips of the modern is checked by the thought, Will the ideas which I am now putting forth, and which I think explain so clearly, so fully, the problem in hand, seem to some

worker in the far future as wrong and as fantastic as do these of my forerunner to me? In either case his personal pride is checked. Further, there is written clearly on each page of the history of science, in characters which cannot be overlooked, the lesson that no scientific truth is born anew, coming by itself and of itself. Each new truth is always the offspring of something which has gone before, becoming in turn the parent of something coming after. In this aspect the man of science is unlike, or seems to be unlike, the poet and the artist. The poet is born, not made; he rises up, no man knowing his beginnings; when he goes away, though men after him may sing his songs for centuries, he himself goes away wholly, having taken with him his mantle, for this he can give to none other. The man of science is not thus creative; he is created. His work, however great it be, is not wholly his own; it is in part the outcome of the work of men who have gone before. Again and again a conception which has made a name great has come not so much by the man's own effort as out of the fulness of time. Again and again we may read in the words of some man of old the outlines of an idea which in later days has shone forth as a great acknowledged truth. From the mouth of the man of old the idea dropped barren, fruitless; the world was not ready for it, and heeded it not; the concomitant and abutting truths which could give it power to work were wanting. Coming back again in later days, the same idea found the world awaiting it; things were in travail preparing for it; and someone, seizing the right moment to put it forth again, leapt into fame. It is not so much the men of science who make science, as some spirit which, born of the truths already won, drives the man of science onward, and uses him to win new truths in turn.

It is because each man of science is not his own master, but one of many obedient servants of an impulse which was at work long before him, and will work long after him, that in science there is no falling back. In respect to other things there may be times of darkness and times of light. There may be risings, decadences, and revivals. In science there is only progress. The path may not be always a straight line, there may be swerving to this side and to that, ideas may seem to return again and again to the same point of the intellectual compass; but it will always be found that they have reached a higher level—they have moved, not in a circle, but in a spiral. Moreover science is not fashioned as is a house, by putting brick to brick, that which is once put remaining as it was put to the end. The growth of science is that of a living being. As in the embryo phase follows phase, and each member of the body puts on in succession different appearances, though all the while the same member, so a scientific conception of one age seems to differ from that of a following age, though it is the same one in the process of being made; and as the dim outlines of the early embryo become, as the being grows more distinct and sharp, like a picture on a screen brought more and more into focus, so the dim gropings and searching of the men of science of old are by repeated approximations wrought into the clear and exact conclusions of later times.

Progress.

The story of natural knowledge, of science, in the 19th century, as, indeed, in preceding centuries, is, I repeat, a story of continued progress. There is in it not so much as a hint of falling back, not even of standing still. What is gained by scientific inquiry is gained for ever: it may be added to, it may seem to be covered up, but it can never be taken away. Confident that the progress will go on, we cannot help peering into the years to come and straining our eyes to foresee what science will become, and what it will do as they roll on. While we do so, the thought must come to us, Will all the increasing knowledge of Nature avail only to change the ways of man—will it have no effect on man himself?

The material good which mankind has gained and is gaining through the advance of science is so imposing as to be obvious to everyone, and the praises of this aspect of science are to be found in the mouths of all. Beyond all doubt science has greatly lessened and has markedly narrowed hardship and suffering; beyond all doubt science has largely increased and has widely diffused ease and comfort. The appliances of science have, as it were, covered with a soft cushion the rough places of life, and that not for the rich only, but also for the poor. So abundant and so prominent are the material benefits of science that in the eyes of many these seem to be the only benefits which she brings. She is often spoken of as if she were useful and nothing more, as if her work were only to administer to the material wants of man.

Is this so? We may begin to doubt it when we reflect that the triumphs of science which bring these material advantages are in their very nature intellectual triumphs. The increasing benefits brought by science are the results of man's increasing mastery over Nature, and that mastery is increasingly a mastery of mind; it is an increasing power to use the forces of what we call inanimate nature in place of the force of his own or other creatures' bodies; it is an increasing use of mind in place of muscle.

Is it to be thought that that which has brought the mind so greatly into play has had no effect on the mind itself? Is that part of the mind which works out scientific truths a mere slavish machine producing results it knows not how, having no part in the good which in its working it brings forth?

What are the qualities, the features of that scientific mind which has wrought, and is working, such great changes in man's relation to Nature? In seeking an answer to this question we have not to inquire into the attributes of genius. Though much of the progress of science seems to take on the form of a series of great steps, each made by some great man, the distinction in science between the great discoverer and the humble worker is one of degree only, not of kind. As I was urging just now, the greatness of many great names in science is often in large part, the greatness of occasion, not of absolute power. The qualities which guide one of man to a small truth silently taking its place among its fellows, as these go to make up progress, are at bottom the same as those by which another man is led to something of which the whole world rings. The features of

The Fruitful Scientific Mind

are in the main three:—In the first place, above all other things, his nature must be one which vibrates in unison with that of which he is in search; the seeker after truth must himself be truthful, truthful with the truthfulness of nature. For the truthfulness of Nature is not wholly the same as that which man sometimes calls truthfulness. It is far more imperious, far more exacting. Man, unscientific man, is often content with "the nearly" and "the almost." Nature never is. It is not her way to call the same two things which differ, though the difference may be measured by less than the thousandth of a milligramme or of a millemètre, or by any other like standard of minuteness. And the man who, carrying the ways of the world into the domain of science, thinks that he may treat Nature's differences in any other way than she treats them herself, will find that she resents his conduct; if he in carelessness or in disdain overlooks the minute difference which she holds out to him as a signal to guide him in his search, the projecting tip, as it were, of some buried treasure, he is bound to go astray, and the more strenuously he struggles on, the farther will he find himself from his true goal.

In the second place, he must be alert of mind. Nature is ever making signs to us, she is ever whispering to us the beginnings of her secrets; the scientific man must be ever on the watch, ready at once to lay hold of Nature's hint, however small—to listen to her whisper, however low.

In the third place, scientific inquiry, though it be pre-eminently an intellectual effort, has need of the moral quality of courage—not so much the courage which helps a man to face a sudden difficulty as the courage of steadfast endurance. Almost every inquiry, certainly every prolonged inquiry, sooner or later goes wrong. The path, at first so straight and clear, grows crooked and gets blocked; the hope and enthusiasm, or even the jaunty ease, with which the inquirer set out, leave him, and he falls into a slough of despond. That is the critical moment calling for courage. Struggling through the slough, he will find on the other side the wicket-gate opening up the real path; losing heart, he will turn back, and add one more stone to the great cairn of the unaccomplished.

But, I hear someone say, these qualities are not the peculiar attributes of the man of science; they may be recognised as belonging to almost everyone who has commanded or deserved success, whatever may have been his walk of life. That is so. That is exactly what I would desire to insist, that the men of science have no peculiar virtues, no special powers. They are ordinary men, their characters are common, even commonplace. Science, as Huxley said, is organised common-sense, and men of science are common men, drilled in the ways of common-sense.

For their life has this feature. Though in themselves they are no stronger, no better, than other men, they possess a strength which, as I just now urged, is not their own, but is that of the science whose servants they are. Even in his apprenticeship the scientific inquirer, while learning what has been done before his time, if he learns it aright, so learns it that what is known will serve him not only as a vantage ground whence to push off into the unknown, but also as a compass to guide him in his course. And when fitted for his work he enters on inquiry itself, what a zealous, anxious guide, what a strict and, because strict, helpful schoolmistress, does Nature make herself to him! Under her care every inquiry, whether it bring the inquirer to a happy issue or seem to end in nought, trains him for the next effort. She so orders her ways that each act of obedience to her makes the next act easier for him, and step by step she leads him on towards that perfect obedience which is complete mastery. Indeed, when we reflect on the potency of

The Discipline of Scientific Inquiry,

we cease to wonder at the progress of scientific knowledge. The results actually gained seem to fall so far short of what under such guidance might have been expected to have been gathered in, that we are fain to conclude that science has called to follow her, for the most part, the poor in intellect and the wayward in spirit. Had she called to her service the many acute minds who have wasted their strength struggling in vain to solve hopeless problems, or who have turned their energies to things other than the increase of knowledge; had she called to her service the many just men who have walked straight without the need of a rod to guide them, how much greater than it has been would have been the progress of science, and how many false teachings would the world have been spared! To men of science themselves, when they consider their favoured lot, the achievements of the past should serve not as a boast, but as a reproach.

If there be any truth in what I have been urging, that the pursuit of scientific inquiry is itself a training of special potency, giving strength to the feeble and keeping in the path those who are inclined to stray, it is obvious that the material gains of science, great as they may be, do not make up all the good which science brings or may bring to man. We especially, perhaps, in these later days, through the rapid development of the physical sciences, are too apt to dwell on the material gains alone. As a child in its infancy looks upon its mother only as a giver of good things, and does not learn till in after days how she was showing her love by carefully training it in the way it should go, so we, too, have thought too much of the gifts of science, overlooking her power to guide.

Man does not live by bread alone, and science brings him more than bread. It is a great thing to make two blades of grass grow where before one alone grew; but it is no less great a thing to help a man to come to a just conclusion on the questions with which he has to deal. We may claim for science that while she is doing the one she may be so used as to do the other also. The dictum just quoted, that science is organised common-sense, may be read as meaning that the common problems of life which common people have to solve are to be solved by the same methods by which the man of science solves his special problems. It follows that the training which does so much for him may be looked to as promising to do much for them. Such aid can come from science on two conditions only. In the first place, this her influence must be acknowledged; she must be duly recognised as a teacher no less than as a hewer of wood and a drawer of water. And the pursuit of science must be followed not by the professional few only, but, at least in such measure as will insure the influence of example, by the many. But this latter point I need not urge before this great Association, whose chief object during more than half a century has been to bring within the fold of science all who would answer to the call. In the second place, it must be understood that the training to be looked for from science is the outcome not of the accumulation of scientific knowledge, but of the practice of scientific inquiry. Man may have at his fingers' ends all the accomplished results and all the current opinions of any one or of all the branches of science, and yet remain wholly unscientific in mind; but no one can have carried out even the humblest research without the spirit of science in some measure resting upon him. And that spirit may in part be caught even without entering upon an actual investigation in search of a new truth. The learner may be led to old truths, even the oldest, in more ways than one. He may be brought abruptly to a truth in its finished form, coming straight to it like a thief climbing over the wall; and the hurry and press of modern life tempt many to adopt this quicker way. Or he may be more slowly guided along the path by which the truth was reached by him who first laid hold of it. It is by this latter way of learning the truth, and by this alone, that learner may hope to catch something at least of the spirit of the scientific inquirer.

This is not the place, nor have I the wish, to plunge into the turmoil of controversy; but, if there be any truth in what I have been urging, then they are wrong who think that in the schooling of the young science can be used with profit only to train those for whom science will be the means of earning their bread. It may be that from the point of view of the pedagogic art the experience of generations has fashioned out of the older studies of literature an instrument of discipline of unusual power, and that the teaching of science is as yet but a rough tool in unpractised hands. That, however, is not an adequate reason why scope should not be given for science to show the value which we claim for it as an intellectual training fitted for all sorts and conditions of men. Nor need the studies of humanity and literature fear her presence in the schools, for if her friends maintain that that teaching is one-sided and therefore misleading, which deals with the doing of man only, and is silent about the works of Nature, in the sight of which he and his doings shrink almost to nothing, she herself would be the

first to admit that that teaching would be equally wrong which deals only with the works of Nature and says nothing about the doings of man, who is, to us at least, Nature's centre.

Science Works for Good.

There is yet another general aspect of science on which I would crave leave to say a word. In that broad field of human life which we call politics, in the struggle not of man with man, but of race with race, science works for good. If we look only on the surface it may at first sight seem otherwise. In no branch of science has there during these later years been greater activity, and more rapid progress, than in that which furnishes the means by which man brings death, suffering, and disaster on his fellow-men. If the healer can look with pride on the increased power which science has given him to alleviate human suffering, and ward off the miseries of disease, the destroyer can look with still greater pride on the power which science has given him to sweep away lives and to work desolation and ruin; while the one has been slowly learning to save units, the other has quickly learnt to slay thousands. But, happily, the very greatness of the modern power of destruction is already becoming a bar to its use, and bids fair—may we hope before long?—wholly to put an end to it; in the words of Tacitus, though in another sense, the very preparations for war, through the character which science gives them, make for peace

Moreover, not in one branch of science only, but in all, there is a deep undercurrent of influence sapping the very foundations of all war. As I have already urged, no feature of scientific inquiry is more marked than the dependence of each step forward on other steps which have been made before. The man of science cannot sit by himself in his own cave weaving out result by his own efforts, unaided by others, heedless of what others have done and are doing. He is but a bit of a great system, a joint in a great machine, and he can only work aright when he is in due touch with his fellow-workers. If his labour is to be what it ought to be, and is to have the weight which it ought to have, he must know what is being done, not by himself, but by others, and by others not of his own land and speaking his tongue only, but also of other lands and of other speech. Hence it comes about that to the man of science the barriers of manners and of speech which pen men into nations become more and more unreal and indistinct. He recognises his fellow-worker, wherever he may live and whatever tongue he may speak, as one who is pushing forward, shoulder to shoulder with him, towards a common goal, as one whom he is helping and who is helping him. The touch of science makes the whole world kin.

The history of the past gives us many examples of this brotherhood of science. In the revival of learning throughout the 16th and 17th centuries, and some way on into the 18th century, the common use of the Latin togue made intercourse easy. In some respect in those earlier days science was more cosmopolitan than it afterwards became. In spite of the difficulties and hardships of travel, the men of science of different lands again and again met each other face to face, heard with their ears, and saw with their eyes what their brethren had to say or to show. The Englishman took the long journey to Italy to study there; the Italian, the Frenchman, and the German wandered from one seat of learning to another; and many a man held a chair in a country not his own. There was help, too, as well as intercourse. The Royal Society of London took upon itself the task of publishing nearly all the works of the great Italian Malpighi; and the brilliant Lavoisier, two years before his own countrymen in their blind fury slew him, received from the same body the highest token which it could give of its esteem. In these closing years of the nineteenth century this great need of

Mutual Knowledge and Common Action

felt by men of science of different lands is being manifested in a special way. Though nowadays what is done anywhere is soon known everywhere, the news of a discovery being often flashed over the globe by telegraph, there is an increasing activity in the direction of organisation to promote international meetings and international co-operation. In almost every science inquirers from many lands now gather together at stated intervals in international congresses to discuss matters which they have in common at heart, and go away each one feeling strengthened by having met his brother. The desire that in the struggle to lay bare the secrets of Nature the least waste of human energy should be incurred is leading more and more to the concerted action of nations combining to attack problems the solution of which is difficult and costly. The determination of standards of measurement, magnetic surveys, the solution of great geodetic problems, the mapping of the heavens and of the earth—all these are being carried on by international organisations.

In this and in other countries men's minds have this long while past been greatly moved by the desire to make fresh efforts to pierce the dark secrets of the forbidding Antarctic regions. Belgium has just made a brave single-handed attempt; a private enterprise sailing from these shores is struggling there now, lost for the present to our view; and this year we in England and our brethren in Germany are, thanks to the promised aid of the respective Governments, and no less to private liberality, in which this Association takes its share, able to begin the preparation of carefully organised expeditions. That international amity of which I am speaking is illustrated by the fact that in this country and in that there is not only a great desire, but a firm purpose, to secure the fullest co-operation between the expeditions which will leave the two shores. If in this momentous attempt any rivalry be shown between the two nations, it will be for each a rivalry, not in forestalling, but in assisting the other. May I add that if the story of the past may seem to give our nation some claim to the seas as more peculiarly our own, that claim bespeaks a duty likewise peculiarly our own to leave no effort untried by which we may plumb the seas' yet unknown depths and trace their yet unknown shores? That claim, if it means anything, means that when nations are joining hands in the dangerous work of exploring the unknown South, the larger burden of the task should fall to Britain's share; it means that we in this country should see to it, and see to it at once, that the concerted Antarctic expedition which in some two years or so will leave the shores of Germany, of England, and, perhaps, of other lands, should, so far as we are concerned, be so equipped and so sustained that the risk of failure and disaster may be made as small, and the hope of being able not merely to snatch a hurried glimpse of lands not yet seen, but to gather in with full hands a rich harvest of the facts which men not of one science only, but of many, long to know, as great as possible.

Another international scientific effort demands a word of notice. The need which every inquirer in science feels to know, and to know quickly, what his fellow-worker, wherever on the globe he may be carrying on his work or making known his results, has done or is doing, led some four years back to a proposal for carrying out by international co-operation a complete current index, issued promptly, of the scientific literature of the world. Though much labour in many lands has been spent upon the undertaking, the project is not yet an accomplished fact. Nor can this, perhaps, be wondered at, when the difficulties of the task are weighed. Difficulties of language, difficulties of driving in one team all the several sciences which, like young horses, wish each to have its head free with leave to go its own way, difficulties mechanical and financial of press and post, difficulties raised by existing interests—these and yet other difficulties are obstacles not easy to be overcome. The most striking and the most encouraging features of the deliberations which have now been going on for three years have been the repeated expressions, coming not from this or that quarter only, but from almost all quarters, of an earnest desire that the effort should succeed, of a sincere belief in the good of

International Co-operation,

and of a willingness to sink as far as possible individual interests for the sake of the common cause. In the face of such a spirit we may surely hope that the many difficulties will ultimately pass out of sight.

Perhaps, however, not the least notable fact of international co-operation in science is the proposal which has been made within the last two years that the leading academies of the world should, by representatives, meet at intervals to discuss questions in which the learned of all lands are interested. A month hence a preliminary meeting of this kind will be held at Wiesbaden; and it is at least probable that the closing year of that nineteenth century in which science has played so great a part may at Paris during the great World's Fair—which every friend, not of science only, but of humanity, trusts may not be put aside or even injured through any untoward event, and which promises to be an occasion not of pleasurable sight-seeing only, but also, by its many international congresses, of international communing in the search for truth—witness the first select Witenagemote of the science of the world.

I make no apology for having thus touched on international co-operation. I should have been wanting, had I not done so, to the memorable occasion of this meeting. A hundred years ago two great nations were grappling with each other in a fierce struggle, which had lasted, with pauses, for many years, and was to last for many years to come; war was on every lip, and in almost every heart. To-day this meeting has, by a common wish, been so arranged that those two nations should, in the persons of their men of science, draw as near together as they can, with nothing but the narrow streak of the Channel between them, in order that they may take counsel together on matters in which they have one interest and a common hope. May we not look upon this brotherly meeting as one of many signs that Science, though she works in a silent manner and in ways unseen by many, is steadily making for peace?

Looking back, then, in this last year of the eighteen hundreds, on the century which is drawing to its close, while we may see in the history of scientific inquiry much which, telling the man of science of his shortcomings and his weakness, bids him be humble, we also see much, perhaps more, which gives him hope. Hope is indeed one of the watchwords of science. In the latter-day writings of some who knew not science, much may be read which shows that the writer is losing or has lost hope in the future of mankind. There are not a few of these; their repeated utterances make a sign of the times. Seeing in matters lying outside science few marks of progress and many tokens of decline or of decay, recognising in science its material benefits only, such men have thoughts of despair when they look forward to the times to come. But if there be any truth in what I have attempted to urge to-night, if the intellectual, if the moral influences of science are no less marked than her material benefits; if, moreover, that which she has done is but the earnest of that which she shall do, such men may pluck up courage and gather strength by laying hold of her garment. We men of science, at least, need not share their views or their fears. Our feet are set, not on the shifting sands of the opinions and of the fancies of the day, but on a solid foundation of verified truth, which by the labours of each succeeding age is made broader and more firm. To us the past is a thing to look back upon, not with regret, not as something which has been lost never to be regained, but with content, as something whose influence is with us still, helping us on our further way. With us, indeed, the past points not to itself, but to the future; the golden age is in front of us, not behind us; that which we do know is a lamp whose brightest beams are shed into the unknown before us, showing us how much there is in front, and lighting up the way to reach it. We are confident in the advance because, as each one of us feels that any step forward which he may make is not ordered by himself alone, and is not the result of his own sole efforts in the present, but is, and that in large measure, the outcome of the labours of others in the past, so each one of us has the sure and certain hope that as the past has helped him, so his efforts, be they great or be they small, will be a help to those to come.

THE OLDEST IRON STEAMSHIP IN THE WORLD.

Of the United States steamer *Michigan*, on Lake Erie, which is the oldest iron steamship in the world, her commander, Lieutenant-Commander C. P. Perkins, gives the following particulars in *Cassier's Magazine* for September:—

The vessel was constructed at Pittsburgh, Pa., in 1841-43; the parts were transferred to Erie, put together and launched on December 5, 1843. The original machinery, with the exception of the boilers, is still in her and in good condition. The vessel is an iron paddle-wheel steamer of 685 tons displacement; length of keel, 156ft. 4in.; length between perpendiculars, 162ft. 6in; breadth of beam, 27ft.; depth of hold, 12ft. 5½in.

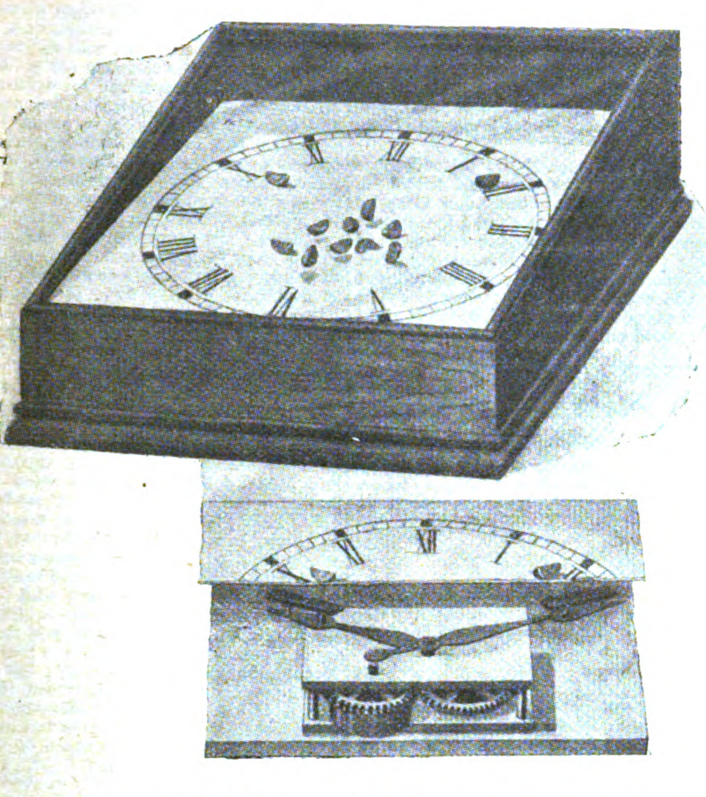
There are two inclined direct-acting engines. The paddle-wheels are of the usual radial kind, 21ft. 6in. diameter, with 16 paddles, 8ft. long by 1ft. 4in. wide. There are two steel boilers of the flue and return fire-tube type, 9ft. 6in. in diameter by 15ft. 2¾in. in length over all; two furnaces in each boiler, 6ft. 6in. by 3ft. 6in. in diameter, and have each a grate surface of 22·75sq.ft. The total grate surface is 91sq.ft., and the heating surface, 1,286sq.ft. There is one smoke-pipe, 4ft. 4in. in diameter, at a height of 42ft. 2in. above the grates. Total weight of boilers, 47 tons.

There are five heavy box keelsons, which run the whole length of the vessel. The distance from centre to centre of frames is 24in.; frames of T-iron, 4½in. by 4in., with reserve bars, 4in. by 2½in.; keel plates, ⅝in. thick; bottom and bilge plates, ⅜in. thick; side plating and run aft, $\frac{5}{16}$in. thick; stem and stern-posts, 6½in. by 1½in.; shear strake and plating carried up to the rail, ⅜in. thick; deck beams are of T-iron.

This vessel has been in continuous service to the present time, over fifty-five years, and is apparently as good for service as ever. During all these years of service no signs of weakness were exhibited.

Her armament at the present time consists of six 6-pounders, two 10-pounder rapid-fire guns, and two machine guns. Of late years her principal occupation has been in the instruction of the United States naval militia at the different Lake ports, and surveying.

At the Brooks Locomotive Works a large locomotive is just being completed for the Illinois Central Railroad. The cylinders are 23in. diameter and 30in. stroke; the drivers are 57in. diameter, and the total weight of the engine, without the tender, is 97 tons.



A MEXICAN BEAN CLOCK.

A FEW years ago public curiosity was excited by the curious beans called the "devil beans of Mexico," which shopkeepers placed in their windows. They somewhat resembled roasted coffee-beans in shape and colour. They were also known as the "jumping-beans," owing to the fact that from time to time they made spasmodic movement which propelled them quite a little distance. The beans grew on a small bush in the Mexican mountains, and it is conjectured that they belonged to the order Euphorbiaceæ. The bean really consisted of three similar pods, which formed a single bean. It is usually a third of the bean which was exhibited as a curiosity. On opening the pods it was found that it contained a small larva, something like that frequently found in chestnuts. It is this little occupant which gives motion to the bean by its jerks and thumps against the side of its home. If the bean is slightly warmed, it begins to turn from side to side, and perhaps with a sudden jump, turns completely over and stands on one end, and then, by successive jumps, moves quite a distance.

Those who are not in the secret are often greatly puzzled by this strange bean. An enterprising jeweller devised a scheme of utilising them to make a magic clock. He accomplished this by imitating the shape of two of the beans, making the dummy beans of soft iron; one he gilded and the other he silvered. The prepared iron beans were placed with the ordinary jumping-beans on a thin white piece of pasteboard, outlined and numbered like the dial of a clock, but devoid of the hands. This dial was located over the works of a large clock, which was placed face upwards on the floor of the store window. He fastened small magnets to the ends of the hands. The works were of course carefully hidden from view. All that was in evidence was the cardboard clock-dial and the jumping-beans, among which were the gold and silver painted iron beans. These were placed on the cardboard over the concealed hands with the magnets attached. The magnets were moved by the hands of the clock so that they were almost in contact with the cardboard. As they moved round they carried the iron beans with them, thus telling the time of day, and the public was greatly interested by the intelligence shown by the two beans, which distinguished themselves from their lively associates.—*Scientific American.*

A MAP OF THE WORLD ON A UNIFORM SCALE OF 1 : 1,000,000.*

THE seventh International Geographical Congress will meet in Berlin on Sept. 27, and among the more generally interesting subjects to be discussed—a list of which has already appeared in the journals of all the principal geographical societies—will be the proposed map of the world on a uniform scale of 1 : 1,000,000. At the fifth congress, held at Berne in 1891, Prof. Albrecht Penck, of the Geographical Institute of the University of Vienna, proposed the construction of a map of the world on this scale, and it was subsequently recommended that the scale be adopted for the purpose by a large and influential committee, whose report was read at the sixth International Geographical Congress held in London in 1895. It was also recommended by this committee that Governments, institutions, societies—in fact, all publishers of maps—should be invited to fall in with the idea of the scheme as far as possible, and adopt this scale, where practicable, in the future, so that there might be in course of time a sufficient area mapped on this scale to bring the accomplishment of the design within measurable distance and warrant the adoption of practical measures.

It was not, of course, to be expected that map-makers would at once set about reconstructing their work on the proposed lines, but it will be seen from what follows that the pronouncement of the congress has apparently influenced those responsible for a very considerable number of maps. As might have been expected from the reputation which it has earned for pioneering in all useful geographical movements, the Royal Geographical Society stands well in the forefront of those who have assisted, either purposely or by force or other circumstances, in contributing towards the accomplishment of this great work. Since the ventilation of the project in 1981 the society has published more than 20 maps on the scale of 1 : 1,000,000. Some of these, it is true, especially those of portions of eastern Africa, may have been plotted on this scale simply for convenience, as the ground-work, in the form of an older map by Mr. Ravenstein, on the required scale, was already in existence. But still the fact remains that this large number of maps on the scale of 1 : 1,000,000 has been brought out by the society. The well-known firm of Justus Perthes, of Gotha, and Diedrich Reimer, of Berlin, have also contributed good work on this scale, the former in *Petermann's Mitteilungen*, and the latter both independently and in conjunction with Dr. Danckelmann in his "Mitteilungen aus den Deutschen Schutzgebieten." Valuable maps, too, have been sent out from Stanford's geographical establishment.

Some idea of what this scale means may be gathered from the fact that the distance from Berwick to Land's End would be represented by a line about 26in. in length; while Africa, from Cape Blanco to Cape Agulhas, would measure 26½ft., and from Cape Verd to Cape Guardafui 24½ft. It will be seen, therefore, that for small countries the scale is not so well suited for general maps of reference, as in the case of larger areas. In all the larger European countries, except Russia, the scale seems to have been pretty generally adopted by the authorities in the construction of maps specially designed to show means of communication and so forth. Thus there is the official railway map of Austria-Hungary published by Artaria, of Vienna, in 1897, for the department of the Government Inspector of Railways. All the lines of communication, railways, canals, postal routes, and telegraph lines are shown on the map, as well as on the railway map of France, brought out in the same year by Mabyre under the auspices of the Ministry of Commerce, which, in addition to the hydrography, shows a large amount of detail, and is hypsometrically coloured. Maupin's map of France appeared in 1892; and a telephone map of the same country has been produced this year; the former of these was published for the Railway Department of the Ministry of Public Works, and the latter for the Post Office. The French General Staff, however, have not adopted the scale, their older railway map, which is now in use, being on the scale of 1 : 1,250,000, while the war map in course of construction is on a scale of 1 : 800,000. In Germany both the firms of Mittler and Son and of Max Pasch have lately published maps for the Railway Department of the Prussian Ministry of Public Works, while in Italy the Military Geographical Institute at Florence produced, in 1894, a map showing railways and navigable waterways—all three of which are on the scale of 1 : 1,000,000, and show a considerable amount of detail. Finally, in Spain, the War Office published a railway map last year which also shows the hydrography; and the postal authorities in Turkey produced a map of 1894 on this scale. All these maps are constructed for special purposes to the exclusion of topographical and orographical detail, and the smaller countries naturally choose larger scales.

Of ordinary maps of European countries showing full detail, very few have been produced on this scale since 1891. Messrs. Reimer and Co. published, in 1895, a map of the German Empire, reduced to the scale of 1 : 1,000,000 by the late Dr. Kiepert and his son; in 1892, August Hahr's map of Sweden, Norway, and Denmark was brought out by the Beijers, of Stockholm, followed in 1895 by Dr. Roth's map of Norway, published by Norstedt; and the Royal Geographical Society have lately brought out a map of Iceland. With these, and possibly one or two other exceptions, the Continent of Europe has not, since 1891, been mapped on this scale. There are, however, several older maps which might be made use of—and in the case of Spain would have to be brought into requisition, as the topographical survey is very far from completion—if it were determined to begin the construction of the map of the world within the next few years. The General Staff map of Sweden, published in 1870, could be used if necessary, and Coello's map of Spain. Then, again, in 1889, Lluillier published a general map of France, by Mezère and Hansen, and in 1885 the Italian Military Geographical Institute brought out a general map of Italy. Both these are on the required scale, and so, too, are the old General Staff map of the Netherlands, which bears the date of 1884, and Bianconi's 1885 map of Servia, published by Chaix, of Paris, as well as Kieppert's Turkey.

With regard to the continent of Asia, the Royal Geographical Society produced in 1893 a map of the Chin and Lushai hills with part of Manipur, followed by Col. Sawyer's reconnaissance survey of the Bakhtiari country in 1894; in 1896 the society published Mr. (now Lord) Curzon's excellent map of the Pamirs and the adjoining territories of Central Asia and India, as well as another map showing Mr. Littledale's routes in Tibet. In 1893 Challamel, of Paris, brought out, under the auspices of the French Foreign and Colonial Offices, the large map embodying the results of what is known as the Pavie Mission to Indo-China, and a new and revised edition of this has recently appeared, which includes all the most recent geographical work derived from English, French, and Siamese sources. This map, which is also on the scale of 1 : 1,000,000, extends as far north as Bhamo and a little further west, so as to include the eastern portion of Burma, while on the south it takes in a good portion of the Malay Peninsula. Further north we have Richthofen's map of the province of Shan-tung published last year by Reimer, and Gustav Kreitner's map, in 17 sheets, of Szechenyi's explorations by Hölzel in 1893. The Japanese Government, also, has brought out a map of Korea, Manchuria, Chi-li and Shan-tung on this scale; and Asia Minor, in several sections, appeared with Murray's new guide to those regions.

The Royal Geographical Society has published a large number of maps of various portions of eastern and south-eastern Africa on the scale of 1 : 1,100,000. In 1891 the map of Jackson's expedition to Uganda appeared, followed in 1892 by one illustrating journeys up the River Tana and to Mount Kenia undertaken by Capt. Dundas, R.N.; and in 1893 came in quick succession a map of the River Jub, also by Capt. Dundas, another of a journey to the east of Mount Kenia done by Lieut. von Höhnel, of the Astor-Chanler Expedition; then the results of the Mombasa-Victoria Railway Survey by Captains Macdonald and Pringle, and a map of the Anglo-Portuguese boundary. In 1894 the society brought out a map of Gregory's journey to Mount Kenia and Lake Baringo; in 1895 one of Mashonaland and Manika, including the lowlands to the Zambesi and Beira, from Selous's surveys. In 1896 Dr. Donaldson Smith's routes in Somaliland and to Lake Rudolf were published, followed, in 1897, by Captain Gibbons's work in Barotseland

* From *The Times.*

and Lieutenant Vandeleur's surveys in Uganda and Unyoro; while a map of Nyasa, by Rhoades and Phillips, and of a part of British Central Africa west of the Loangwe River, by Hoste, were issued last year, and a map of the Nyasa-Tanganyika Plateau, by the members of the commission for the delimitation of the Anglo-German boundary, has only lately appeared, as well as a map of Lake Choga and district by Captain Kirkpatrick. In addition to these the Royal Geographical Society also published in 1895 a map of part of the south-eastern portion of the Congo Free State to illustrate Mr. Hinde's explorations, and another of Morocco to accompany a paper by Mr. Harris. It will be seen that nearly all these will serve to bring up to date the large map of Eastern Africa, to which allusion has already been made, and which was compiled by Mr. Ravenstein and published, under the authority of the Royal Geographical Society, by Mr. Stanford in 1882. This map extends from 10° N. to 20° S. and from 25° E. to the Indian Ocean, and includes the Horn of Africa. Included in the same area are three maps published by Justus Perthes in *Petermann's Mitteilungen*—viz., Emin's routes to the west of Lakes Victoria and Albert, which appeared in 1892, Kolb's map of Ukambani and the Kenia district, which came out in 1896, and Count Wickenburg's routes in Somaliland, mapped by Paulitschke in 1898. The same compiler's map of the routes of Hoyos and Condenhove appeared in the "Mitteilungen aus den Deutschen Schutzgebieten" in 1894. In that year also the Italian Ministry of War brought out a map of Ethiopia in two forms, planimetria and altimetria, which embraces the area contained between 5° and 19° N. and 35° and 47° E. In 1896 the Portugese Government began the publication of a map of their Eastern African possessions, which is not yet completed, though the portion south of the Zambesi has been done. In 1891 and 1893 there appeared in the bulletin of the Italian Geographical Society the Somaliland explorations of Bricchetti - Robecchi. In 1893 Bandi de Vesme's routes from Berbera to Bur Dap were published by Guido Cora in Cosmos, and in 1896 a map showing the route of the second Bottego Expedition as far as Sankurar appeared in the memoirs of the Italian Geographical Society. Murray's 1897 "Handbook" contains a map of Egypt and the Nile as far as Khartum on the scale of 1 : 1,000,000, and there is also one of Lower Egypt in Baedeker's 1895 edition. Stanford's large map of Rhodesia, in six sheets, covers the country between 8° and 23° and 20° and 37° E.; this came out in 1896, and the same publisher's "Transvaal Goldfields" in the same year; while his "Western Somaliland" appeared in 1898, and his enlarged map of the South African Republic has just been brought out. A map, on the scale of 1 : 1,000,000, of the railway from Delagoa Bay to Johannesburg accompanied a consular report which appeared in 1894; Carl Wiese's explorations in the Western Nyasaland Goldfields were published by Rugg in 1892, and finally Ghika's routes in Somaliland were mapped by Paulitschke, and published by Bannwerth, of Vienna, in 1897.

Turning to the West of Africa, we have De Roquevaire's excellent map of Morocco, published by Barrère, of Paris, in 1897; Binger's map of the Upper Niger, reaching south to the Gulf of Guinea, produced by the Service Géographique des Colonies in 1893; Vuillot's course of the Niger, which was brought out by the Paris Geographical Society in 1894, and the same author's lake region of Gundam, which appeared in the *Bulletin du Comité de l'Afrique Française* in 1896. In this magazine also appeared a map of Chanoine's Gurunsi mission last year, while Eysserio's Ivory Coast journeys were published in the "Annales de Géographie," and Wauters brought out a map of the lower Congo, illustrating the railway works, in the "Mouvement Géographique," Brussels. In his book describing his ninth journey in the Sahara, Foureau has a map on this scale covering a considerable tract of country.

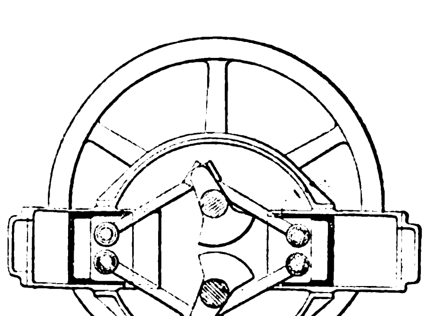
In Central America we have Bianconi's commercial map of Honduras and Salvador, dated 1891, and a map of Costa Rica by Colonel Church, brought out by the Royal Geographical Society in 1897. In South America, which has now almost robbed Africa of its title of "the Dark Continent," there are a few maps on the scale of 1 : 1,000,000, notably Dr. Brackebusch's Argentina, which was published by Hellfarth, of Gotha, in 1891. Siemiradzki's map of the Limay district of north-west Patagonia appeared in *Petermann's Mitteilungen* in 1893; while Dr. Fischer's map of the results of his Rio Palena expedition was published at Santiago in 1894. In the following year Capello produced his map of the route between Callao and Ucayali at Lima; and Steffen's map of the Rio Puelo come out in Petermann. Finally, Regel's journeys in the north-west of the United States of Colombia were illustrated by a map on this scale, which was published in the Verhandlungen of the Berlin Geographical Society.

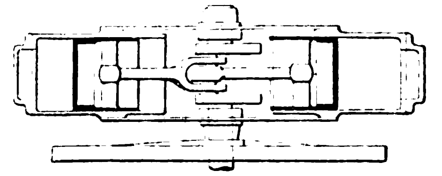
In the Australasian Archipelago there are also three maps which deserve attention—viz., Nijland's Java, which appears as an inset in his map of the East and West Indies, and was brought out b Breijer, of Utrecht, of 1891—a series of twelve sheets which cover the islands of Sumatra, Bangka, and the Riouw archipelago, executed by Dornseiffer and De Geest, and published by Seyffardt, of Amsterdam, in 1892 and 1896; and the results of the explorations of the brothers Sarasin in Celebes, which appeared in the *Zeitschrift* of the Berlin Geographical Society.

It will be seen that most of the better-known geographical societies of the Continent contribute something to this somewhat formidable array of maps, the output of nearly nine years; and this is, perhaps, one of the most encouraging deductions to be drawn from a perusal of the list. Another has already been mentioned—namely, the adoption of the scale by the various departments concerned in the production of special maps constructed to show chiefly the means of communication.

BALANCED ENGINES FOR MOTOR-CARS.

THE annexed illustrations show a balanced engine patented in this country, which the *Practical Engineer* says has been used with great success for





propelling motor-cars. The two crank-shafts being geared together, the gears not showing, equal quantities of angular momentum are imparted to each. Both the reciprocating and the turning moments are balanced and neutralised, or nearly so. The gist of the invention is contained in the patent claim, which is as follows:—"In motive-power engines, a method of balancing by arranging two oppositely rotating crank-shafts between them, and connecting the piston of each cylinder by two connecting-rods, one rod to each rotating crank-shaft. A motor constructed in this manner runs with practically as little vibration as a rotary engine or turbine."

MUSICAL PITCH.

THE question of musical pitch has, through the action of some of the leading pianoforte-makers, been again introduced into public discussion, says Mr. A. J. Hipkins, in *Nature*. That it should end in the general adoption of the French diapason normal hardly admits of a doubt, especially as it is in the United Kingdom only there remain any advocates for the high pitch formerly general. France introduced by law the diapason normal in 1859, and has been gradually followed by Belgium and Italy, Germany and Austria, Russia and the United States of America, leaving this country in musical isolation from which a great effort has yet to be made to bring it into uniformity with other musical countries, so that the note A will be approximately the same here as anywhere else, and not give the impression or a transposition. The difference of vibration number is not so very much; if it were a semitone it might be easier rectified—at least in concert organs; it may be stated at $\frac{5}{8}$ths, or at most $\frac{2}{3}$rds, of an equal semitone. It is measurement and the important consideration of temperature that justify the admission of a subject, at the first aspect merely artistic, into the columns of *Nature*. Temperature has as yet met with insufficient consideration. It is hardly alluded to in the "Sensations of Tone" by Helmholtz; it meets with a bare mention only, although somewhat extended, in the footnotes of the English translator, the late Dr. A. J. Ellis, who refers (p. 90, second edition) to the experimental work in that direction of Mr. Blaikley.

It is well known that the Paris diapason normal is stated as A = 870 vibrations a second at 15° C. As we reckon by complete vibrations, we take this number at one-half (435), with the temperature by the Fahrenheit thermometer (59°). Although this is a very good temperature for open-air music, as military bands, &c., it is not high enough for operas and concerts taking place in confined spaces with audiences and artificial lighting. The opera and concert orchestras have, therefore, everywhere to find their own pitch evolved from the Paris standard to suit an average increase of temperature. If the French Commission had decided upon 20° C. (68° Fahr.), the necessity for an empiric proceeding would have been avoided. They might very well have adopted Scheibler's suggestion, made in 1834 at Stuttgart, of A = 440. It is known that he worked at a temperature of about 70° Fahr. To him we owe the only facile tonometer, for which his pitch was really A = 439·5. It is well to go back to the protocols of the Congress at Vienna in 1885, which led to the adoption of the French pitch in Austro-Hungary. After a unanimous acceptance of the diapason normal at 15° C. it was proposed that, in order to keep the wind instruments in performance to the initial standard vibration number, A = 430, the brass and wood wind instruments, and also the organ, should be made for 24° C. (75.2° Fahr.)!—thus introducing a second standard to be used concurrently with the first, the necessity attributable to the vibration number being increased automatically by the heating and rarefaction of the air increasing its velocity, and with the orchestral wind instruments by the breath and handling of the players. Mr. Blaikley has shown the velocity of air in pipes is always less than in free air, possibly through the friction of the walls; but in the organ flue-pipes it comes so near to free air that the organ may be almost regarded as a thermometer. So high a temperature as 24° C. was not left unchallenged; a wiser determination was urged of 20°, which in practice would have proved right. However, the great differences likely to arise in average temperatures due to climatic conditions, and to warming and lighting apparatus, as for instance, gas or electricity, prevented a decision from being arrived at; so that Vienna is now, as London was, pending the decision of the Philharmonic Society, using a convenient empiric pitch of about A = 440 for concert performances. Ingenious as the Viennese plan in 1885 would have been, it is wiser to have one standard, with one note A for its expression, and one mean temperature. For brass instrument makers a B-flat fork may be used, and to suit the old custom of organ-builders and pianoforte-makers, a C fork; but in preparing them equal temperament should be rigidly observed.

In 1879, at the instance of Mme. Adelina Patti, the Covent Garden Opera adopted French pitch; a recent trial in performance satisfied me that it was at A = 440, the temperature being about 70° Fahr., and that there had been no departure from the intention of using the French standard. Little notice has at any time been taken of this important change at the Opera; but when the Queen's Hall was opened in 1893, Mr. Newman, the manager, and Mr. H. J. Wood, the conductor, lost no time in introducing the diapason normal for all performances for which they were responsible, the proprietors going to the expense of having the organ, which had just been built at the high pitch, lowered. Mr. Henschel, in his symphony concerts at St. James's Hall, and in founding the Scottish orchestra, speedily followed. But the decisive point for this country was reached when, in July, 1896, the Philharmonic Society, the most eminent musical institution in this country, elected to adopt the French diapason normal, and in the following November decided to have a standard tuning-fork for their concerts. Having consulted me, the directors accepted my suggestion for that pitch that it should be A = 439 at 68° Fahr. Forks made for the Society by Valantine and Carr, of Sheffield, were verified by me with the aid of the Scheibler tonometer in the Science Department, South Kensington, and besides the one retained by the Society, accurate copies were presented by the directors to the Science and Art Department, the Society of Arts, the Royal Academy of Music, the Royal College of Music, the Guildhall School, Trinity College, London, and myself; the last being accessible on all lawful days at Messrs. John Broadwood and Sons, 33, Great Pulteney-street, W. The B flat is stated in the same minute of the Society as = 465, the C = 522—this last happens to be a just minor third above A = 435, an accidental, although useful, coincidence.

The vibration number 439 is really the French standard raised to an average performing temperature, theoretically by my coefficient of a thousandth part of a complete vibration a second for one degree Fahrenheit, so that for 435 the rise for the next degree is ·435. In a variety of ways I have sought an average concert temperature, which I have finally taken at 68°, at which strings, wind, organ, and piano should be in tune. According to my coefficient A = 435 at 59° should be A = 438·98 at 68°. The round number 439 is more convenient. Briefly expressed, my coefficient is ·5 per degree for C = 500, nearly, if not quite, the rise in free air.

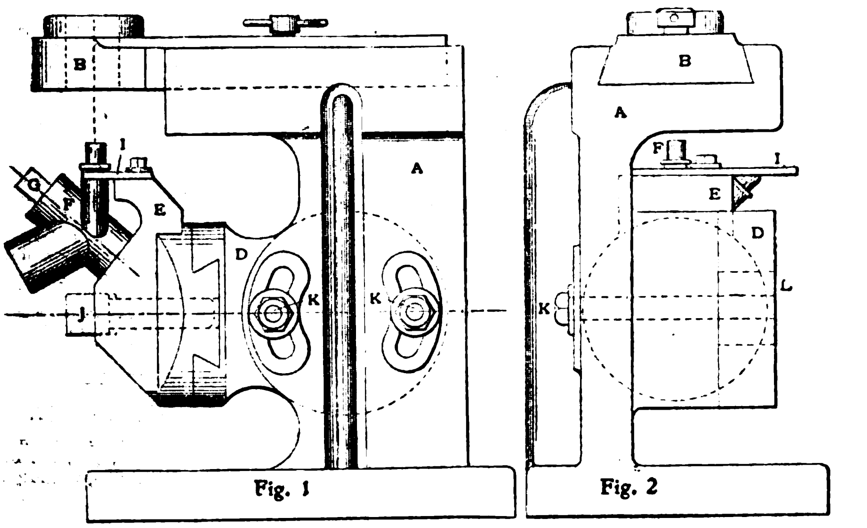


Fig. 1 Fig. 2

According to Helmholtz, the velocity of sound in dry air is at 0° C. (32° Fahr.) 322 mètres = 1,089·3ft., say 1,090ft.; according to Dr. Ellis, at 60° Fahr. the velocity is 1,200ft. per second—with this my coefficient practically agrees. In further justification, I quote the Covent Garden A = 440; the same vibration number for pianos, communicated to me by Herr Seuffert (Bösendorfer's), Vienna; the clarinet of Herr Mühlfeld, of Meiningen and Bayreuth, A = 439·5, it being understood when warm; a comple trial of all the wind instruments of Mr. Henschel's orchestra with a piano tuned to A = 439 in a room exactly at 68° Fahr.; and, lastly, the crowning triumph of the Lamoureux orchestra from Paris joining forces with the Queen's Hall orchestra in London this year, the accuracy of pitch in the performance being unassailable, A = 439! I should like to add for organs my trials of the St. James's Hall organ, at 52° C = 531 and at 72° C = 541, as one of the many comparisons of this nature; and conclude with Prof. Blaserna's report of a trial at Vienna, 1885, when A = 435 at 15° C., warmed to 30° C., became A = 457·7, equivalent to raising A to a tempered B flat. If a piano were supplied for a concert intended to be French pitch, at the standard fork A = 435, in London or Paris, Berlin or Vienna, it would be too flat for performance. It would be a concession of great importance, which the musical world could not be too grateful for, if the Paris diapason normal were revised for the higher temperature, 20° C., and legalised A.D. 1900, for France at A = 439. Our Philharmonic Society has shown the way, the rest of the world would soon follow. Neither the stability of pitch of the tuning-fork nor that of a pianoforte during a concert need be considered. Dr. Ellis gives the flattening of tuning-fork as 1 in 16,000 per degree Fahrenheit; Mr. Blaikley and myself in one trial only of a concert pianoforte, ·025 per degree; but for the short time a concert lasts this must be imperceptible, the elasticity of the music-wire having to be reckoned with against the least change of tension.

The objections to the A = 439 that have been urged are that wind instrument makers may take it as a starting-point for a lower temperature than 68°; but not if they are conscientious? We can legislate for this no more than we can for the tendency to exceed the present high pitch, as is shown by our military bands, and the majority of the brass bands in this country, in spite of Kneller Hall, which is bound to maintain the old Philharmonic pitch until the War Office releases the army from it, and provides or sanctions French pitch bands. Organ-builders who can work with accurate)rks and a thermometer will have no difficulty with th French pitch; indeed, nearly all are in favour of it, as are the pianoforte-makers and dealers generally; but there are some who seem to fear their instruments will suffer in brilliancy of effect by the reduction. When, however, we consider the rise in the tension of pianos during the last thirty years, due to improvement in music-wire and to a great change of construction, causing in grand pianos a rise in tension equivalent to a minor third in pitch, or more; and when we reflect that the difference of pitch proposed in tuning to the new Philharmonic is only ⅔ths of an equal semitone, we may see in the change more a gain than a loss by a possible increased fulness of tone-quality, and, above all, we shall have uniformity with the rest of the musical world.

A DE LAVAL steam-turbine motor has been used in a slate mine for running a ventilating plant. The high speed of the turbine is reduced by means of gearing, so that the actual speed of the fan is about 1,000 revolutions per minute.

AN ADJUSTABLE JIG.*

THE jig described in this article is for doing work on the bicycle part known as the seat-post union, and is so constructed as to get the cuts on different sized pieces, and also the different cuts on the same piece with one jig. This jig was designed by Mr. J. R. Foster, the foreman of the machine shop in the Peoria Rubber Company. Anyone familiar with the requirements in this will appreciate the ingenuity displayed in providing for the peculiar difficulties presented by the angles of the piece F. The drawing describes the jig pretty completely, but a few parts may be mentioned.

The frame A carries an adjustable slide B for moving the bushing forward or back; also a sub-frame D carrying another sliding-piece E. D swivels on the solid post L, a part of A being held in position with the bolts K K. The different positions of the parts when once made for different operations are carefully marked, so that resetting for any part of the work is easy. The work being handled in lots, resetting is but little trouble.

H, Fig. 3, is a post with an expansion-screw G for holding the work, and I is a sliding gauge for locating the arms of F, first for one side and then

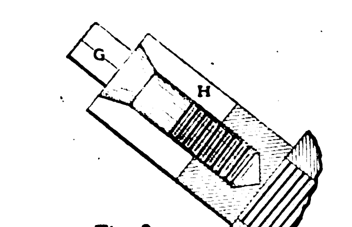

Fig. 3

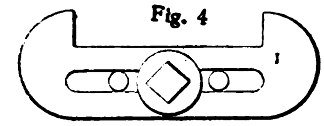
Fig. 4



for the other. The set-screws C and J secure the sliding-pieces B and E in position very effectively and simply by bottoming on the castings A and D.

I intended to mention in a former article that the band-saw blades used in the manufacturing department, after being dulled somewhat for that class of work, do good service in the machine shop, being used in a Stover Novelty Company's hack-saw machine.

This is provided with a box for holding a continuous saw blade, and while it is not so rigid as some other machines, and does not cut off large work so straight, is very convenient for smaller work, and the saws mentioned are broken off and moved along with the least inconvenience.

* By A. H. CLEAVES, in *American Machinist.*

PROMOTION FOR SPIDERS.

THERE are signs that in the twentieth century the humble spider, whose creative talents have long been wasted in spinning endless traps to catch miserable little flies, will be promoted to a higher sphere of usefulness. He seems predestined to furnish the lov·li·r part of humanity with her most choice apparel, although the sceptical might fancy that a dress of cobweb, h·wever suitable to fairies, would scarcely pass muster in the City of London. Adopted by man, and relieved from the necessity of earning a precarious livelihood by expedients of doubtful morality, the spider is capable of much. Already the French military balloonists are breeding and taming spiders to yield fibres for their balloon cords. About a dozen tame spiders furnish the fibres to make a thread. The spiders are placed in a machine, and the fibre is drawn out automatically a certain length at a time. These fibres are pink in colour, and after being washed, to remove the sticky matter on them, are united in a thread, and these threads are spun into cords for balloons, which for their weight are much stronger than silk. Several species of the insect are adapted for this domestication, but the most promising is the "Halaba," or silk-spider, of Madagascar.—*Cassell's.*

THE SCREW PROPELLER.

WITH reference to the question "Who made the Screw Propeller a Success?" there will probably always be as much diversity of opinion as about the best form of the "propeller" itself, and every marine engineer knows that that is a good subject for discussion if it is desired to make a meeting "lively." Who first invented or suggested the use of the screw as a means of propelling vessels through the water has always been a matter of dispute, and now it seems that the question of who made the propeller a success is coming up again. Hooke (1680) and others subsequently suggested the use of the screw; but it would appear that the credit of the first application of the propeller to sea-going vessels is due to Col. John Stevens, of Hoboken, New Jersey, who, in 1804, constructed a boat, still preserved in the Stevens Institute of Technology, which is said to have attained "considerable speed" in that year. There is an English patent granted in 1794 to Lyttleton; but Stevens (followed by Fulton) seems to have been the first to make really practical trials. F. P. Smith obtained a patent in this country in May, 1836, and Ericsson obtained another in July, 1836. The fact appears to be that many inventors had turned their attention to the subject, and in the "Life of Isambard Kingdom Brunel" (London: Longmans, 1870) there is an account of Brunel's interview with the Admiralty, when a model of "Mr. Brunel's mode of applying the screw to Her Majesty's ships" was presented to his view for the first time. That was in 1841, and Sir G. Cockburn, the first Naval Lord, asked Mr. Brunel: "Do you mean to suppose that we shall cut up Her Majesty's ships after this fashion, sir?" Mr. Brunel said he knew nothing about the model, and whilst an inquiry was being made, quietly cut off the inscription with his knife. That anecdote, which is well known, shows how the opposition of the officials of the Navy often prevented, or tried to prevent, improvement. We mentioned last week that "Justice" (p. 68) had sent us some papers on the subject, one of which is a letter addressed by Mr. Henry Wimshurst to *Engineering*, dated March 5, 1879, in the course of which he says:—"The screw propeller had been under experiment for very many years before either Mr. Smith or myself were known to it, although these experiments ended in failure. My claim to merit does not, therefore, rest upon its introduction, as claimed for others by your correspondents, but from my having found it wrongly shaped, and applied in a wrongly-shaped boat, and from that position I elevated it to a better form, and applied it in a better manner, in a properly-formed ship, thereby making the use of the screw a commercial success, so much so that the second screw vessel which I designed and built, I, as the owner, sent under charter to foreign ports. The facts are as follow, and most of them are even yet capable of proof:—In 1836 Mr. Smith (who was then a draper and silk mercer at Hithe, and afterwards a farmer at Hendon) did, with the assistance of Mr. Wright, banker, and others, raise some £2,000 to test the merits of the screw as a propeller. They then had a little boat built by a boatbuilder at Wapping named Gulliver. This boat was about 30ft. in length, 9ft. in breadth, and 4ft. in depth. The propeller conpeller consists of a short log of elm cut to form one whole turn round the shaft, and it was situated in an aperture, or well, 7ft. forward of the sternpost. The boat where cut to form the aperture presented partial bulkheads—the one before and the other abaft the propeller—thus having a part only of the screw effective as a propeller. When this boat so finished was tested, no good result could be obtained, and a committee of four gentlemen, on behalf of the Licensed Victuallers Company—viz., Messrs. J. Ferguson, pilot; Charles Cutts, shipwright; Samuel Seaward, engineer; and E. Pascoe, N.A.; was thereupon formed to look into the matter, to make further tests, and report progress. Their report was in all respects so thoroughly unsatisfactory to the screw as a propeller that it was determined to go no further with the screw, and as the company were then wanting a passenger steamer, it was determined that the boat should be paddle-wh·el, and she was afterwards named the *City of Boulogne.*" Mr. Wimshurst then proceeds to tell how he com-

menced to build the *Archimedes* in May, 1838, and how he made a propeller having two blades, each less than a half-turn in length, which gave an increased speed to the vessel. Messrs. Ericsson, Woodcroft, Lowe, and others, were present at most of the experiments. Mr. Wimshurst advertised in the *Times*, December, 1842, challenging the production of any paddle-wheel vessel then afloat of twice the horse-power of the *Novelty*, which he had built, and which made the first commercial voyage with the propeller. The challenge does not seem to have been accepted, although the odds were against the screw.

The reprint from the *Nautical Magazine* of 1876, referred to by "Justice" on p. 68, contains diagrams of the propeller as fitted to the earliest ships in this country, and will be useful to those who wish to understand the history of the invention. Meantime we quote the following article from the *Times* of April 12, 1855, which may be of interest, apart from its special subject, because it shows how the leading newspapers dealt with technical matters in those days.

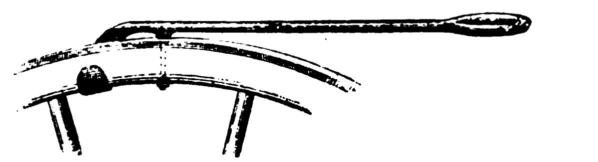
"Few great inventors have possessed the practical talents for business of Watt or Wedgwood. It is with the pioneers of science as with the pioneers of civilisation. They point out the way and clear the paths along which others are to travel with more fortunate results, at least, to themselves. Such has been the well-nigh universal story until quite in modern times. We, however, affect in this respect to be better than our fathers. We say, 'Let us be made aware of the real merits and claims of men who have rendered eminent service to their country, and adorned their age by great scientific discoveries, and, if they cannot help themselves, they shall not remain without fitting reward. They may be able, single-handed, to enrich themselves by means of commerce—we will help them with our patent laws and injunctions. They—the men of speculation—may have the good sense to take into partnership men of action and everyday sagacity, and so by united efforts promote the profit of both. But, failing all this, they shall not be left without compensation. If nothing else can be done, at least a definite sum of money may be collected, in proportion to the importance of their discoveries; and thus they themselves will be rewarded, and other men encouraged to proceed in the same course.' We live in age of 'testimonials,' as they are called. They are forced upon Protectionist squires in return for their patriotic services in promoting the best interests of the country, rightly understood. Slippers by the thousand pairs, worked by taper fingers innumerable, are unctuously laid at the feet of the Rev. Josiah Boltall. The originator of potichomanie has not been forgotten, nor the most finished adept in the science of picking locks. Churchwardens, demagogues, cotton-spinners, soldiers, have all had their turn; no one, in fact, seems to have been forgotten, save the man who has contrived the greatest mechanical improvement of which the present age has yet had notice. It may seem incredible, but it is nevertheless true, that the only man overlooked in this age of testimonials, distinctions, and honorary rewards, is the inventor of the screw-propeller—Mr. Smith. The object of our remarks this day is to bring the case of this gentleman—for surely it involves a great anomaly—before our readers. The point is forced upon our attention by the circumstances of the time. There was lately an announcement to the effect that the *Trafalgar*, a splendid three-decker enough as ships went in former days, had just reached England, having been 84 days out from Malta on her homeward voyage. Well-nigh three months, in other words, were spent upon a run which, by the help of Mr. Smith's invention, might easily have been accomplished in ten days. Consider, again, the list of those 'leviathians afloat' which have just left the shores of England for the Baltic campaign. A large draught of the entire naval force of England is there, and the power of this draught has been multiplied tenfold by the use of the screw-propeller. It is, indeed, scarcely fair, in such a case as this, to speak of the multiplication of strength in a tenfold—aye, or in a fiftyfold degree. More correct is it to say that the conditions of naval warfare have been altogether altered, and in every way to the advantage of this country, by this new application of mechanical power. To naval armaments has been communicated well-nigh the gift of ubiquity. They are no longer at the mercy of contrary winds; they cannot be detained in distant ports at a critical time when their presence is needed elsewhere. If we are to find a Troy in the Crimea, at least there is no Aulis for the British fleets. Again, they can undertake services which they dared not have attempted, even under the guidance of a Nelson or a Troubridge, when Sir John Jervis held the command of that wonderful Mediterranean fleet. The screw defies the perils of a lee shore. An enemy can now be brought to action from whatever quarter the wind may blow; henceforward there need be little or no manœuvring for the weather gauge. Let the enemies of England but dare to show themselves on the open sea—let them venture but for half a day from behind the protection of their batteries and stone walls, and we think we may without arrogance venture to say it, they will have but little inclination to bless the name of the inventor of the screw-propeller.

"Of course, now the thing is done, it appears to be a simple matter enough—quite as obvious as printing, or gunpowder, or steam-power, or the electric telegraph. Very second-rate men can readily make improvements on the original idea, but the question is, who first showed them the ground upon which they could plant a stable foot? Most of us have been acquainted at one time or another of our lives with inventors. There are plenty of them about, for nothing is more common than a moderate capacity for mechanics. It is grievous to add that persons possessed of this faculty in a minor degree are among the most tiresome and pedantic of companions. They will insist upon cramming their crude suggestions down the throats of men who are honest enough to admit that they know nothing about the matter, but are content to leave it in the hands of suitable persons. Now we cannot remember any point in the whole range of all possible mechanical improvements upon which there has been more discussion than upon new methods of propelling steamships through the water. The defects of the old paddle were obvious even to unscientific men; the question was as to the fittest substitute. There were innumerable propositions for modifying the action of the floats upon the water. Motive power was to be applied by wheels rotating astern or forward. The paddle-wheels amidships were to be protected in a hundred different ways from the peril of hostile shot; but why dig out exploded projects from the limbo of oblivion? Many of these inventions may, no doubt, have possessed merits which we are not in a condition to appreciate, through our own defects of knowledge; all persons who may be curious on such points can see hundreds of them embodied in the form of models in the Museum of the Society of Arts, or at the Polytechnic Institution. Thus much, however, is clear—not one of them found general acceptance with the world until Mr. Smith took the matter in hand, and invented the form of propeller now in use. On such a point surely success is the best test of merit. Even if his successors improve upon his model, the fact will still remain unchanged that he pointed out the way and set their brains to work. Upon the advantages which have resulted from this important discovery it would be a simple insult to the understanding of our readers if we were to say another word. They are not confined to war and warships alone. Merchant vessels can now reckon upon secure runs. The greatest portion of their time may be still spent under canvas, should the heavens prove propitious; but when adverse gales or tedious calms threaten to prolong the voyage, and to add indefinitely to the expenses of the owners, the steam is got up, the screw let down, and away goes the good ship on her appointed path, in defiance of obstacles which ten years ago would have proved insurmountable to the most skilful seaman with the means then at his disposal.

"Under these circumstances it is not without sufficient cause if we bring the case of Mr. Smith before the notice of Englishmen. Where so many miserable quacks and impostors have partaken largely of the public bounty, surely it were no unfitting thing if a provision were made for a man who has conferred so great and substantial a benefit upon his country. No doubt, it is perfectly right that all persons who may be inclined to take the matter in hand should be satisfied that Mr. Smith is really the originator of the idea, and that he has not as yet reaped from it any such benefit himself as he was entitled to expect. Let these and similar points receive the most ample and the most public discussion. If we thought that the gentleman of whom we write had any occasion to shrink from the most absolute publicity, we should not have troubled our readers with two lines upon the subject. But, should it prove that these allegations are, in point of fact, strictly true, it will remain a permanent disgrace to the country if a man who has been so greatly its benefactor be suffered to pine away in obscurity without any adequate reward for his successful industry and skill in contriving and perfecting an invention which has added in so high a degree to the wealth, the power, and the security of the British Empire."

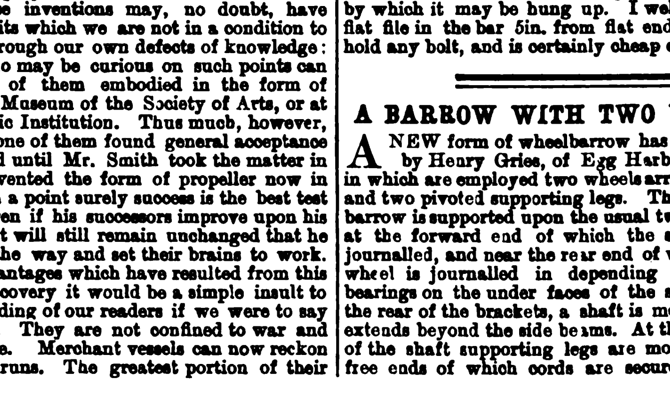
TIRE BOLT-HOLDER.

THE tire bolt-holder shown in the annexed engraving is considered a very good one by Mr. E. Bemis, of Pison, Ohio, who, writing to the *Blacksmith and Wheelwright*, says:—"I herewith send you a rough sketch of one that I have used for at least twenty years, it being home-made. I never saw one like it. It will hold any bolt in any size rim, so that it is impossible for it to turn, and if sufficient pressure is used will cut a slot in the head of the bolt like a screw-head. The handle is made of ½in. or ⅝in. round iron, 20in. long, or more; with end flattened and twisted so as to fit around the felloe; the other end being welded into a ring by which it may be hung up. I welded a piece of flat file in the bar 5in. from flat end and this will hold any bolt, and is certainly cheap enough."



A BARROW WITH TWO WHEELS.

A NEW form of wheelbarrow has been invented by Henry Gries, of Egg Harbor City, N.J., in which are employed two wheels arranged tandem and two pivoted supporting legs. The body of the barrow is supported upon the usual two side beams, at the forward end of which the small wheel is journalled, and near the rear end of which a larger wheel is journalled in depending brackets. In bearings on the under faces of the side beams, at the rear of the brackets, a shaft is mounted, which extends beyond the side beams. At the extremities of the shaft supporting legs are mounted, to the free ends of which cords are secured, which are reeved through eyes on the body and side beams, and provided with rings adapted to engage with pins on the ends of the handle. When the barrow has received its load, the cords are drawn back and attached to the side beams, thus carrying the legs out of contact with the groud, as shown by dotted lines in the illustration. When the barrow is not in motion, the cords are disconnected and the legs permitted to drop to the ground. The legs are held in their supporting position by means of removable pins passed through above the shaft. Stops on the side beams, in front of the shaft, prevent the barrow from moving forward.



A barrow thus constructed, it is claimed, will enable one to carry heavier loads with less fatigue than heretofore, because the larger rear-wheel supports the entire weight.—*Scientific American.*

PENNY-IN-THE-SLOT TELEPHONES.

IT is most astonishing, but a fact nevertheless, that in matters electrical Great Britain is moving very slowly indeed, being continually outdistanced by the United States, Germany, and even France.

As a novelty, we hear, says *Commercial Intelligence*, from Berlin of the introduction of automatic telephones on the penny-in-the-slot principle, which by way of trial are being put up at various public places and pleasure resorts by the German Post Office authorities.

These little apparatuses are connected with the nearest telephone exchange, at which, on the insertion of a nickel ten-pfennig piece (about a penny) into the slot, a bell is set ringing, when the wants of the customer are inquired into, and communication established between him and any telephone subscriber in the Berlin district, for a period of not more than three minutes.

Should this experiment prove a success, of which there can be scarcely any doubt, it is the intention of the German Post Office to establish this means of communication broadcast all over Germany.

Meanwhile, here in London every foreigner shrugs his shoulders at our ridiculously costly and inefficient private-capitalist-throttled telephone system.

USEFUL AND SCIENTIFIC NOTES.

A CANADIAN has invented an electric foghorn. It consists of two funnels made of ⅛in. copper. The funnels project 6ft. 6in. from a stand at right angles to each other. In each of these funnels or horns a vibrator or sound-producer is placed, the object being to use them alternately or simultaneously, as may be desired. A group of electro-magnets, made up of laminated iron cores wound in the ordinary way, is employed, and the instrument is operated by means of alternating currents.

A FRENCH magazine, devoted to the clockmaking trade, gives the following process for restoring nickel, and the majority of metals subject to tarnish, to their original colour:—Dissolve 0·40 to 0·45 gramme of cyanide of potassium in half a glass of water, plunge the objects into this solution, and withdraw them immediately. A simple rinsing with water suffices to remove every trace of acid. Next plunge them in spirit of wine, and dry them in sawdust to preserve from rust.

THE Bethlehem Steel Company recently despatched from its works the shaft of an engine for the Boston Elevated Railroad. This shaft and the parts attached weighed 170,400lb., which is said to have been the heaviest load ever sent by rail, except the Krupp gun which the Pennsylvania Railroad carried to the World's Fair. The shaft was taken from Bethlehem by the Philadelphia and Reading Railroad, and was carried on two cars. It was made for an engine built by the Corliss Steam-Engine Company, is 37in. in diameter at the middle, and hollow forged, with a 17in. bore. It is 27ft. 10in. long.

To secure the smokeless working of passenger engines on the Cincinnati, New Orleans, and Texas Pacific Railroad, the fireboxes are fitted with hollow brick arches, and four holes are made in each side of the firebox for the purpose of admitting air, and four tubes run through the arch. The outside air passing through these tubes is heated to a high temperature. This heated air supplies oxygen to the unconsumed gases, and is said to produce complete combustion. The four holes in the side of the firebox are placed 12in. above the grates, and into these openings are inserted air-tubes for deflecting the air to the fire.

Aluminium for Cooking Vessels.—Prof. Chatterton, of the College of Engineering and the School of Arts, Madras, writes to the *Madras Mail* stating that the manufacture of domestic utensils, and the like, of aluminium, is making a great stride in India. The work was originally started at the School of Art, but there are now several other centres of manufacture, and the more general adoption of the metal is being hastened by the prevailing high prices of copper and tin. A large order for cooking vessels for the 28th Madras Infantry has recently been filled at the school. These vessels have almost of necessity to be made by hand, since each native regiment has its own patterns. The production of a suitable water bottle is, however, a difficulty, as the flat pattern is not easily made in aluminium since soldering cannot be used; whilst a cylindrical pattern cannot be conveniently carried. Aluminium has also recently been used as a bearing metal for shafting in the Madras College of Engineering, and has proved satisfactory. The school has also recently supplied a complete set of railway carriage fittings made of this metal, and for taps, cocks, and other small articles, it is, Prof. Chatterton states, superior to brass.

SCIENTIFIC NEWS.

IT is announced that another small planet has been observed by M. Jean Mascart, of the Paris Observatory, on Aug. 26.

The *Bulletin* of the Société Astronomique de France for September contains an article on "La Photographie des Spectres d'Etoiles," by M. A. Cornu, and one on some new observations of the planet Mars made at Juvisy by MM. Flammarion and Antoniadi, which will be of great interest to students of Areography. There is a paper by M. Em. Touchet on "La Lumière de Vénus et l'Ombre qu'elle produit," and another by M. L. Rudaux on "Des Satellites de Jupiter," which will attract attention.

Dr. A. M. W. Downing, F.R.S., superintendent of the *Nautical Almanac*, has published, through Neill and Co., Limited, of Edinburgh, "Precession Tables adapted to Newcomb's Value of the Precessional Constant." The epoch adopted is 1910, but the tables are so constructed that they can be used with facility for at least ten years before and after that date. The tables have been arranged so as to give the values of the precessions corresponding to Newcomb's value of the precessional constant as deduced by him in accordance with the request made at the conference held in Paris in 1896.

The San Francisco correspondent of a morning paper says that: "Prof. Campbell announces that the Lick telescope has resolved the Polaris into a triple system, including two bodies which revolve round each other in a period of four days. Simultaneously, they revolve together around a third body, as the stars and moon revolve around the sun. It is improbable that any of these bodies are ever separately visible, their existence being revealed by spectroscopic methods. Fourteen discoveries like this have been made at the Lick Observatory, but this is the most interesting, surpassing even that of Capella."

The death is announced of M. Gaston Tissandier, the famous aëronaut and the founder and editor of *La Nature*. He made forty-four ascents, in one of which (1875) his companions Sivel and Croce Spinelli were suffocated. M. Tissandier had reached the age of fifty-six.

The Congress of the Royal Institute of Public Health will be held in Blackpool, Sept. 21 to 28, under the presidency of the Marquis of Lorne. There are four sections, one of them being devoted to engineering and building construction.

The distribution of medals and prizes to the students of the Royal College of Science will take place in the lecture theatre of the Victoria and Albert Museum on Oct. 5 (Thursday), when Prof. Rücker will deliver the address.

Lieut. Peary's expedition to the Polar regions does not seem to have been remarkable, although it is stated that it reached 50 miles further north than Nansen's. Lieut. Peary, however, was not bent on reaching the Pole, and has done some good work in exploring Grimell Land and its western extremity. The *Windward* returns in the spring, when Lieut. Peary will commence the three years' further prosecution of his search for the Pole.

All hope of finding Andrée's expedition seems to be abandoned, the Danish expedition under Lieut. Amstrup having returned to Mandal, after a year's absence, without having found a trace. A Reuter message from Malmo gives a similar account of the expedition under Prof. Nathorst. The Swedish expedition reports that it explored Franz Josef Fjord, on the east coast of Greenland, and there discovered a whole series of new inlets, the positions of which were charted. An interesting ethnographical collection relating to the now extinct Esquimaux population was secured in that region by the explorers.

The experiments in wireless telegraphy which were to be made at the meeting of the British Association may have to be postponed, as Signor Marconi is leaving for America in order to consider the question of the possibility of obtaining wireless communication between America and this country. It is stated that direct communication has now been established between Boulogne and Dover. Until the present trials it was believed that these cross-Channel communications would have to be retransmitted through the South Foreland, but direct communication has now been obtained between Boulogne and Dover, which is another scientific triumph for the new telegraphy. These interesting effects are to be demonstrated during the meeting of the British Association, the installation being placed in a railed inclosure, so that the members generally can see the operations. At the South Foreland the top of the pole is about 550ft. above sea-level. In the valley at Dover it is only about 150ft. above the level of the sea, and yet with all this difference it has now been proved that the results which can be obtained are equally efficient. "Such are the possibilities of wireless telegraphy that it would appear that a new development might at any time occur which would place the curvature of the earth to a great extent out of the question and permit infinitely greater distances to be traversed," so says the *Times*; but it would be wise to doubt the "infinitely greater distances."

In a memoir presented to the Paris Academy of Sciences, M. Maltézos points out that the ordinary equation gives no explanation of the phenomenon of beats in vibrating strings, and it appears from his investigations that it is nearly impossible to explain all the phenomena of beats in vibrating strings. It is certainly impossible to explain them from rigidity alone.

The first subaqueous tunnel in Germany is at the present time in course of construction under the River Spree in Berlin. It is intended to accommodate a tramway route connecting the Silesian railway-station with the suburb of Treptow, and has a total length, including approaches, of 2,020ft., 1,500ft. of which constitute the tunnel proper. Since the introduction of iron as a substitute for the older stone or brick linings of tunnels, the usual method has been to construct them of cast-iron segments, which are bolted together through flanges and lugs provided for the purpose. In the tunnel under the Spree cast-iron is discarded for steel, which forms a cylindrical casing having an internal diameter of 13ft. 2in. The lowest part of the tube is 35ft. beneath the mean water-level of the river, so that, given a depth of water of 11ft., there remains a thickness of the same amount between the upper part of the tunnel and the bed of the stream. Steel plates 2ft. 3in. in length, with their butt joints covered by double-angle steel, are built up to form the lining, and are protected externally from corrosion by a thick layer of cement. In the lower part, or invert, concrete is used to bring the floor of the tunnel up to track level, below which is laid a longitudinal drain to carry off any water that might accumulate, which will be pumped out as required by electric power. The piercing of the tunnel was effected by the shield and compressed air through strata composed of mud and dirty sand of a most unfavourable description, the maximum hydraulic pressure available amounting to 900 tons. The work was commenced in 1895, and it is expected that the tunnel will be opened for traffic next year.

According to a Reuter's message, the Dowager Empress of China has requested Mr. Pritchard Morgan to proceed to China, and to commence mining operations in the province of Szechuan. Mr. Morgan will, it is stated, leave in time to reach Pekin by the end of October, and will take a staff of geologists under the direction of Dr. R. L. Jack, formerly Government geologist of Queensland.

It is announced that the German Post-Office is about to introduce "self-propelled" vehicles, using electro-motors for the parcel waggons, and some "benzine" motor waggons will also be employed. In this country the motor-car post-office waggons are to be shelved, for the present, as they have not been altogether satisfactory in keeping time.

The following paragraph is at once a curiosity and a revelation:—"Mr. F. Coburn, a local naturalist and taxidermist, gives in the *Birmingham Mail* an account of a visit recently paid by him to Northern Iceland to study the nesting habits of certain birds that visit our shores, and to obtain specimens. He prides himself on having by his two-months' expedition cleared up many points relating to the habits and ways of birds that have long been in dispute, and to have established the error of several prevalent impressions. He has brought home with him 323 specimens belonging to fifty different species, besides eggs and nests. In Iceland, singular as it may seem, the law governing the shooting of wild birds is stricter even than ours. Some you are not permitted to touch at all; others are protected by a close season; and others, again, are only to be taken with the authority of the land-

owner, who is the tenant, for in Iceland they have anticipated the social reformer of our own country, and the land belongs to the people. Mr. Coburn added, as a curious fact (!), that during the whole of the time he was in Iceland he neither saw nor had occasion to use artificial light. He worked at any part of the night or day by the light of the sun."

Mr. Frank E. Lowe, writing from St. Stephen's Vicarage, Guernsey, says that the "long-tailed blue" (butterfly) has been abundant:—"On Sept. 1, I took eleven, including two females, and daily since I have taken some. On Sept. 1, I netted thirty-three specimens in all. This species is very rare in Northern and Central Europe, though not uncommon on the Mediterranean coast and Asia, extending to Australia and the Cape. Its sudden appearance, therefore, in numbers in this little spot, in spite of its reputed tendencies for migration, is very perplexing. Messrs. Newman and Tutt, in their respective 'Histories of British Butterflies,' quoting evidently the same authority, say, 'In 1859 the species was abundant in the Channel Islands.' Perhaps this refers to Jersey, but as to Guernsey, I believe the facts are these. In 1859 Miss Renouf took eight specimens of L. Bœtica, and one more in August, 1872. The next recorded capture is one by myself in this same garden on Sept. 15, 1892. About two years earlier, a schoolboy is reported also to have taken a battered specimen on the sea-coast. Thus it will be seen that it is forty years since more than one specimen has been taken in the same season in this island, and now they are to be had *ad lib.*"

According to a report by Lieut.-Col. Addison issued on Saturday, the collision at Wimbledon on May 8 would seem to have been due to a "want of care." The inspector says: "I have to point out that while the second, and fatal, collision was due to most regrettable want of ordinary care on the part of more than one of the company's servants, the first collision—which was the originating cause of the second one—must, in my opinion, be largely attributed to an unsatisfactory system of working, and, to some extent at any rate, to the station staff being inadequate to the requirements of this busy place. The system is plainly very defective, when it admits of the signalman pulling off a signal for an engine to move in one direction at the same time that a shunter may be, unknown to the signalman, taking another engine across, or foul of, the road made for the first one. I consider that a thoroughly experienced shunter should be in charge of the yard, under whose orders the signalman should set the points, pull off signals, &c., and the shunter should be the only person authorised to allow any train or engine to be put in motion. Had shunter Kimber remained in the sidings with engine No. 668, I think the first collision could hardly have occurred, but even then the system in vogue would seem to have permitted Kimber and Webber (with the goods train) to be acting independently—which should not be the case. Kimber left his engine because, as I have already pointed out, his services were required in the station. A man cannot advantageously perform the double duties of a shunter and platform porter, and the serious attention of the company should be drawn to the necessity for making proper provision for these duties with as little delay as possible." It remains to be seen what the directors of the company will do.

In his article on "Climbs in the Andes in 1898," in the *Alpine Journal*, Sir Martin Conway tells us that Lake Titicaca is fourteen times as large as the Lake of Geneva, and lies at an altitude of 12,600ft. above the level of the sea. A mountain railway finds its way up to this great lake, and the passengers are transferred to a steamboat if they wish to cross Titicaca.

The Great Salt Lake, in Utah, 4,000ft. above the sea-level, is dwindling. For three decades its shore line has been steadily contracting and its depth growing less. The Mormon system of irrigation cuts off the fresh supplies from the mountains, the lake consequently lies stagnant, at the mercy of the sun. Four rivers empty themselves into the lake, which it used to be thought, was fed also by hidden springs. From these rivers comes all the water for the irrigation of the Jordan valley in Utah. The evaporation is not regarded as very serious; the lake is a wonder and a salt factory only. But should the fresh waters of Utah Lake also dry up, thousands of square miles would cease to be habitable.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor *of the* English Mechanic, 332, *Strand, W.C.*

**** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

THE AUGUST PERSEIDS, 1899.

[42810.]—It is a pity some of your correspondents did not commence their observations a few days earlier, as possibly we might have had an additional feature or two. To me the forerunners of the shower began to arrive as early as the 4th, on which date I saw two—one a stationary at 10h. 11m., this is the fourth time—from the usual centre near Eta. On the 8th I counted ten Perseids, radiation diffuse. On the 10th and 11th the meteors fell pretty constantly, but they did not seem so strong as in previous years. I placed the maximum at 60 per hour at 11 till 11.30 local time on the 11th. Display fell off next evening, and by the 14th everything was much as usual. The sub-radiants noticed were one near Beta Andromedæ at 10° + 38°, and one at about 70° + 55°.

If Mr. Beasley's dozen radiants are all Perseids, the stream, as we traverse it, would seem to consist of threads of meteors, each thread giving its own radiant—hence number and variety.

Belfast, Sept. 10. **W. H. Milligan.**

WEATHER OF AUGUST, 1899.

[42811.]—Supplementary to the usual letters about the phenomenal weather of the past month of August, it may be of interest to add that the amount of evaporation from a 6in. gauge here exhibits also high figures of 1·925in. or ·065in. per diem. This is higher than that for August, 1898, 1·460in. or ·047in. per diem, and for August, 1897, 1·225in. or ·040in. per diem, and for August, 1896, 1·410in. or ·042in. per diem. The present excess of one third more of evaporation is evidently exceptional, and may be due to the greater receptivity of the air occasioned by a general anti-cyclone of dry atmosphere continuing for about 21 days—a longer period than usual.

The relation between the rainfall and the evaporation is interesting as showing their interdependence, as there was in May a heavy fall here of 3·130in., followed in June by an evaporation of 1·950in. or ·065in. per diem, and a heavy rain in July of 4·230in., followed by an evaporation of 1·925in. or ·068in. per diem in August.

The total rainfall here for May, June, July, and August was 8·405in. or ·068in. per diem, and the total evaporation here was 7·265in. or ·060in. per diem, so that it would appear that all the rain has not been evaporated by the abnormal heat, and that there would be no occasion to consider the advent of any drought in this quarter. Some rain is estimated, therefore, to have been left here for the supplies of springs and streams, and thus to dissipate any grounds for apprehending an inconvenient drought over the country side, as it has a substantial balance of 1·140in. to go on with for the following month. **W. G. Black, F.R.M.S.**

Edinburgh, Sept. 3.

METEOROLOGY AND WEATHER PREDICTION.

[42812.]—There is no doubt something of a science of meteorology, but as to weather prediction it is no further advanced than it was in the time of Admiral Fitzroy. The following is a specimen of what is published about weather:—"Now what does all this point to? Clearly to greater stability and constancy in the climate. 'Is this not so?' asked a newspaper representative at the Metereological Office. 'Well, all I will say,' was the reply, "is that, not now particularly, but frequently during past years, I have noticed 'tendencies' to wet cycles of years, dry cycles of years, and so forth.'

"'And the reason?'

"'Ah! well, now you are asking a poser; it is a secret locked in the bosom of Nature; something, I should think, to do with the comparative distribution of atmospheric pressure over the Northern Hemisphere.'

"By the way, the present summer has been the driest experienced for 30 years."

The meteorological records for fifty and more years show conclusively that to predict weather is hopeless, unless the district is specified; for considering that in so small a piece of the earth as England, there is annually a difference of about 100in. in the rainfall (say between Cumberland and Norfolk), any prognostication must be local, and then what becomes of the cycles? I note that Mr. McDowall's latest (p. 60) refers to "London" winters, which seems a more scientific way of treating the matter than to speak as if "weather" applied all over the globe, or even all over Europe. **M. E. V.**

THE BRITISH ASTRONOMICAL ASSOCIATION AND THE ROYAL ASTRONOMICAL SOCIETY.

[42813.]—The comments of the "Fellow of the Royal Astronomical Society" (p. 88) on this subject are what might have been expected, and it remains only for me to assure him that the passage referred to is correctly quoted. When noticing such matters I make a practice of cutting the paper in which the sentences appear, and do not trust to transcribing. It is pardonable for printers to make errors in setting up type from manuscript, but not when set from print. As a matter of fact, I cut out the passages referred to before breakfast, and I believe they are correctly printed. They should be, as they were taken bodily from the paper in which they appeared, and I quite agree that the critic "is talking nonsense, pure and simple."

To the comments of "Eel Hay" (p. 89) I have nothing to say. **An Old Printer.**

GREGORIANS—γ^2 ANDROMEDÆ—TO "ELL HAY."

[42814.]—This contributor will be pleased to know that at the earliest opportunity I shall make my best endeavours to assist him in releasing himself from the unfortunate tangle into which he has allowed himself to fall among the uncompromising facts concerning the Gregorian telescope adduced by me in 42757 and elsewhere.

"Ell Hay" has entirely forgotten that the authorities I gave by name in 42757 as *observers* who favoured direct vision were all famous *practical* astronomers, and that those given as *opticians*, in the true sense of that term, were all quite as famous with their hands as with their heads. "Ell Hay's" assertion that the entire lot were "mere theorists like 'H.' himself" (see 42783) bodes ill for the validity of his other conclusions. For if such men as Dr. Robinson, of the Armagh Observatory, Sir G. Airy, the late Astronomer Royal, Barlow, Potter, Pritchard, Coddington, &c., all thoroughly *practical* authorities on the questions raised by your correspondent, are to be considered "mere theorists," as "E. H." says, "where be we?"

For the numerous kind things which "E. H." has said of me, I hope I am truly grateful; but when he classes me among the above-named illustrious "theorists," I must perforce disclaim, for, like all competent practitioners, these men were one and all perfectly at home in theory as well as practice, while poor "H." himself has always held his theoretical equipment as but very inferior to his instrumental and practical one, under which circumstances alone perhaps "E. H." ought to sympathise with, rather than ridicule, him. The practical work of the observatory, the use of graduated instruments of precision, and of telescopes of all kinds, from the actual construction of every part of some of which he has derived much pleasure, have together taken up very much more of "H.'s" time than optical theory has ever done (it is, I believe, of this particular "theoretical" shortcoming he stands accused). But need he complain, since to be thrown into the company he falls into in letter 42783 is only too flattering a compliment?

Need it be here repeated that Lord Rosse's requirements, his facilities, and the scale on which he worked made it almost a necessity that the telescope he constructed should be a Newtonian or a Herschelian. I thought this had been already sufficiently made plain; but, of course, Rosse being perhaps the most exclusively "practical" man, astronomically as well as optically, on my list, his corroborative testimony *in favour of direct vision telescopes*, where possible, had to be quibbled aside, as it is in "E. H.'s" reply (42783).

The question concerning the particular "green" of γ^2 Andromedæ (which Halley the second denies, see 42783), although perhaps already explained to the entire satisfaction and comprehension of the average reader, is I find placed again before me by that correspondent, and, as formerly, I shall not spare myself trouble in trying to gratify his wishes, as soon as opportunity offers, on which occasion I shall also clear off his entire score, and the mysterious "friend," so frequently spoken of, can then start in whenever he likes. **H.**

THE COMET AND THE DELUGE.

[42815.]—Cometary astronomy has made, strictly, only one advance since Newton's time,

namely, to prove comets vastly more numerous than he or anyone of his time fancied. Encounters between them and the earth are probably a hundred times more frequent than his data would enable us to reckon.

The foundations for believing an encounter in 3102 B.C. are really Halley's and his own, with several added from geology. We have numerous geological proofs of a world-wide catastrophe 50 centuries ago, or, at least, less than 60. But there was no catastrophe in 2358 B.C., because Hindoos, Chinese, and other ancient nations have older records. Morever, the fact of the Jews altering their Genesis is well known. But a Deluge in 3102 B.C. is recorded by all ancient peoples; and the Hebrew story thereof was not only believed by Christ, but made by Him a basis of His religion. Two Gospels, Matt. xxiv. 38, and Luke xvii. 27, make this plain. In fact, if the story were allegorical, as Mr. May thinks, there could be no Christianity whatever, as he must be well aware.

Breakneck Lyell invented this fallacy, which Darwin afterwards believed; but both were supreme asses for not seeing that cometary astronomy utterly clashes with them. Darwin, in his famous but absurd book, the "Origin of Species," wants "300 million years" for denuding the English weald; but what of the *hundreds* of comets encountered in that time? We are meeting, at least, four per million years. He was much honester in collecting facts than Lyell, and hence his books will always be valuable; but his origin of species by natural selection is ridiculous. Christians ought to have seen this, long before he wrote his "Origin of Species." E. L. Garbett.

REDUCING INTENSITY OF LIGHT—HELPS TO DOUBLE-STAR SEPARATION.

[42816.]—IN view of several recent communications bearing upon the initial part of above heading, among which are those of "J. F. B." (42628), "A. S. L." (42649), Wm. F. A. Ellison (42662 and 42752), R. J. Ryle (42688), "U" (42694), S. B. Gaythorpe (42711), N. Maclachan (42716), and "J. M. W." (42729), it might not be altogether out of place were I to add my little quota. Space sternly prevents me from entering into anything like a proper discussion of the various methods put forward in above-quoted letters, but it may be permissible to add some remarks upon a few points which have been either passed over perfunctorily, or have escaped notice altogether, omitting the costly polarisation methods.

First, we may, I think, take it as settled by general experience that, except for very small apertures, or in combination with other means the "dark-glass" method of reducing brilliancy is unsatisfactory, and not altogether free from risk to the observer's eye.

Second—that the "dark glass" as "fitted into the ordinary draw tube" or into short tubes to fit the field-lens settings of the eye-pieces, as made by Ross for some of his customers, although free from above risk, is less satisfactory than the first plan optically, from the fact that its situation causes it to intercept the rays at different angles to its surface at a place where these rays are far from being parallel, a disturbance resulting which does not occur when the pencils consist of parallel rays (or nearly so) as they do *outside* the eye-lens. (Of course the working of special curves on the dark glass would obviate the disturbance, but this, I believe, is never done; and even if done, the dark glass would then only act perfectly with one eyepiece.)

Third—that the introduction of a diaphragm to limit the aperture, admitting as it does of very great diversity of effect, depending upon the situation as well as the size and shape of the opening, has, as might be expected, given rise to considerable differences of opinion as to its effects.

Fourth—that diaphragms with multiple openings otherwise "perforated screens," to use the customary parlance, have, from their more varied effects, given rise to a still greater difference of opinion—some well-known authorities recommending them with much confidence, others, considering themselves "observers," as confidently condemning their use.

Fifth—that revolving screens, of variously shaped aperture, have also received consideration theoretically at least, but that practice is almost silent on this method.

Such, I take it, has been the experience or reading of your various contributors. In dismissing the method of intercepting the light between the eyelens and the eye, let me, however, observe that one very effective means of doing this has been left, if I mistake not, unmentioned by any of your correspondents—I mean the fluid cell, the performance of which I have personally found most satisfactory. The darkening medium, a filtered dilution of common iron ink with distilled water, first recommended, I believe, by Sir Wm. Herschel, is inclosed between two parallel plates fitted into the ends of a short cylinder or ring of from about $\frac{1}{2}$in. to $\frac{3}{4}$in. in length, and a small hole in the ring fitted with a watertight screw gives means for filling, for altering depth of shade, or emptying. When long out of use it must, in fact, be emptied and washed out, as there is a tendency to incrustation or deposit on the glass if left filled for a protracted period. By this means solar observations become most pleasant, the comparatively *cool* image of the sun being reduced to an intensity suited to ordinary vision, while its colour appears perfectly natural, being almost pure white.

As the athermanous action of plain water is to that of the much-praised "alum solution" as 11 to 13, by recent determinations, the above "cooling" effect can be understood. There is, however, one drawback concerning its use with *refractors*—viz., the required thickness of medium, including that of the retaining glasses, permits of its use only with very low powers, if the field of view is to be serviceable. On the other hand, with the *compound* reflector its thickness is no obstacle, and even with the highest powers available, its use is perfectly satisfactory. (See letter on construction of Gregorian eyepiece.) Were this fluid cell to be placed between the lenses, or in front of the field-lens, its surface would, as in the case of the above-mentioned dark glass, require to be worked to special curves. I have computed such curves, but have never found reason to depart from its use between the eye-lens and the eye. I can thoroughly recommend its use to amateur observers of solar spots, &c. It might be thought that heat currents set up in the liquid by the passing rays would disturb vision; but in practice I have never been able to notice such a defect.

Coming now to the third class of devices—viz., diaphragms, it may be noted that, as most of us know, this is the means taken to preserve the "webs" of transit instruments, altazimuths, &c., from destruction when they are used for solar observations; the heat, as well as the light, being diminished with the aperture, or rather as the square root of the aperture. The usual perforated lens-cap serves this purpose, the full aperture never being used on the sun. But still the dark-glass must be used also, for the diminution of light required by the eye would need an aperture (if used without the dark-glass) too small to allow of decent definition of the sun's limb. It is needless also to say that as possibly no object-glass is so thoroughly corrected for spherical aberration as to give the same focal length, masked and unmasked, the necessary shift of the "web" (a matter seldom possible) must, unless carefully made allowance for, introduce serious errors into micrometer work. Positions for the diaphragm, other than just in front of the object-glass, introduce too many complications to receive further notice here.

The fourth method, or that of the "perforated screen" placed usually near the object-glass or over the open end of the reflecting telescope, next claims attention.

To start with, I may mention that long before I became acquainted with Mr. Dawes's use of this method (although his aim was somewhat different), I saw a most accomplished mathematician and careful practical observer, lately deceased, frequently use it in the form of a Cambric handkerchief thrown over the object-glass of his instrument, when observations were made on the sun. I confess these observations were ostensibly for "position" only, and not for the examination of physical details, for which latter purpose I consider the method but imperfectly suited, although for the sun's limb, or as I shall show for double-star work, the definition is very perfect. Indeed one of your contributors, Mr. Wm. Rowland, of Leeds, mentions this very method, with "fine Brussels net" in letter 38652, May 1, 1896.

I can quite substantiate Mr. Dawes's opinion of the "screen" as already quoted second-hand in your pages from "Chambers's Handbook of Astronomy," p. 285.

There Dawes is stated to have found this expedient to be "capable of producing a sharpness of definition he considered to be very marked."

Dawes used "cardboard, such as that employed in Berlin-wool work," placed just in front of his object-glass. My own experience has been in favour of fine "net," having meshes about $\frac{1}{25}$in. wide, which upon the whole I find to answers best; but different telescopes apparently require different sizes of mesh. For detail upon *surfaces* of sensible extent, I have not found, as might be expected from the diffraction phenomena developed, the screen an improvement to definition—rather the reverse; but for double-star work I have found it of great benefit, where the light will permit of the consequent diminution in intensity. The effect seems to be the following:—The greater part of the field, with the exception of a well-marked dark area just round the star, is filled with a dim, hazy light, from the very considerable increase in the number of diffraction rings, and their complicated interferences, many of which produce the appearance of minute hazy ghost images of the star being examined. Round the star itself, however, the small area of almost perfect blackness, with the cutting off of any "fringes" which the opens lens may show, and the very decided diminution of the star discs, conspire to admit of the best possible scrutiny of the adjacent points of light, to which as almost mere points the star discs are now reduced. Sir J. Herschel says, in the case of a mist or cloud, to which the gauze screen is in some respects similar, "the intervention of a cloud which reduces their brightness *reduces also their apparent discs* (italics mine) till they become mere points." Sometimes I have been able to separate difficult double-stars by using a screen when the naked object-glass or speculum showed only a doubtful elongation. Readers may recollect than in the case of some uncharitable criticisms recently seen in "Ours" upon the work of certain double-star observers, I said in letter 42048, Feb. 17, "I am inclined to think that some of our contributors are not in ignorance of the effect of a muslin screen, else their remarks would be less confident," meaning by that that in using the means just discussed, they may have been able to see with their apertures what others, observing by the only means *they* knew of, failed to make out. H.

EFFECTS OF CHANGE OF TEMPERATURE.

[42817.]—IF Mr. Tanton has correctly quoted, this textbook is certainly wrong. Chasles' law should run: "If the pressure remains constant, an increase of temperature 1° C. produces in a given mass of any gas an expansion of ·003665 of its volume at 0° C."

What Mr. Tanton has assumed is that an increase of temperature by 1° C. produces an increase of ·003665 of the volume of a certain mass of gas *at any temperature*, other than 0° C. Here lies the error.

Trin. Coll. Oxon. J. M. W.

[42818.]—MR. W. E. Tanton (letter 42807) I fear has rushed into print without properly thinking out his subject. He says let V = original volume, a = coefficient of expansion, r = volume of 1c.ft., after the temperature has been raised 1° Then he goes on to say: "V r = the volume after the t has been raised 1°." But according to his formula V r would surely be the "original volume. The volume after the temperature has been raised 1°."

The proper way to state the case is thus: "That the relation between volume and temperature is such that if a given volume of gas be raised at constant pressure, from 0° C to 1° C., it will increase in volume by approximately $\frac{1}{273}$ of its original volume at 0° C." (*Vide* "Heat and Light," by R. Wallace Stewart, B.Sc., W. B. Clive and Co.)

At 100° C. the volume would be $\frac{100}{273}$ of its volume at 0° C., and so on. Hence −273° C. is denominated absolute zero. Theoretically the volume would then be reduced to nothing. But that is physically impossible. Air liquefies at a given temperature, and lower still becomes solid, when of course different laws must govern its expansion and contraction. W. F. Webb.

[42819.]—MR. W. E. TANTON has not as yet seriously threatened the veracity of textbooks on heat. (See letter 42807, p. 93.) The reason for his conclusions being wrong is that he improperly uses the coefficient of expansion. In other words, he arrives at the volume for an increase in temperature of 1° C. by the correct coefficient, and at the volume for increases of temperature of more than 1° C. by the correct coefficient plus one. Also he multiplies by his coefficient instead of adding.

Let me try to make this clear by working the formula—

Let V = original volume of gas in cubic feet.
a = coefficient of increase of volume of gas.
t = increase of temperature.

1c.ft. of gas increases for a rise of temperature of 1° C. by a c.ft.
Therefore V c.ft. of gas increase for a rise of temperature of 1° C. by $a \times$ V c.ft.
Therefore V c.ft. of gas increase for a rise of temperature of t° C. by $a \times$ V $\times$ t c.ft.
Therefore volume of V c.ft. of gas after a rise of t° C. is V + $a \times$ V $\times$ t c.ft., or $Vt = V(1 + at)$.
For a fall in temperature, formula is $Vt = V(1 - at)$.

If Mr. Tanton will work examples with these formulæ, he will see that the textbooks are perfectly right, and absolute zero is a possibility if Charles' law is perfect. W. B. M. M.

WHO MADE THE SCREW PROPELLER A SUCCESS?

[42820.]—"JUSTICE," in your issue of Sept. 1 (42769, page 681) says, "We are seeking facts, and to speak from memory is apt to mislead."

In my previous letter (42728, page 40) I wrote entirely from memory, as the subject is so accurately engrafted in my brain that I could not possibly make a mistake in reference to it, and as "Justice" has thought fit to send reprints of the press of 1876 and 1879 to substantiate his views on the subject, which no doubt have reference to

Mr. Wimshurst's statements contained in a printed paper on the subject (I have documents that will refute such statements) to the Right Honourable W. E. Gladstone, M.P., &c., in 1872 or thereabouts, I have now turned up my papers and correspondence which has lain dormant for many years, and forward a cutting from the *Times* of April 12, 1855, which leaves no doubt whatever as to who was the promoter and perfector of the screw-propeller. May I ask you to insert it? I could also forward copy of the *Daily News* of May 17, 1856; the *Sun*, April 18, 1855; *United Service Gazette*, April 21, 1855, and May 19, 1855; the *Bankers' Journal*, April 14, 1855; *Herapath's Journal*, April 15, 1855; *Naval and Military Gazette*, May 19, 1855; the *Engineer*, May 2, 1856; the *Observer*, May 19, 1856, and can produce many others of an anterior date, all of which give the credit of perfecting the screw to a practical development to Smith. None of them have any reference to Wimshurst whatever. Anyone desirous to verify the above could obtain those reports.

I think, Mr. Editor, that I have stated sufficient proof, and can more if required, as to who made the screw-propeller a success, and desire to close this controversy.

King's Lynn, Sept. 4. **C. P. Pilgrim.**

[See p. 111 for an article on the subject. Those who are interested have now practically all the data, and must form their opinions according to the statements published.]

WORKERS FOR SCIENCE.

[42821.]—I HAVE been more interested than I can say in Sir Michael Foster's Presidential address yesterday at Dover, abstracts of which I have read to-day in the daily papers, and a fuller *résumé* of which I trust you are giving this week in accordance with your usual practice.

The point which specially impresses me is the regret expressed by the President that, comparatively, so few devote themselves to the pursuit of the knowledge that after all is surely the only subject worthy of the attention of mankind. Politics, trade, law, letters, and the like engross the attention of nine-tenths of us, and the recruits for science are few and far between. Is it not time something were done to alter this, and to train up the coming generations in the service of science, that the abundant promise of the last hundred years may bear fruit a hundredfold during the coming century?

I feel sure there are thousands of fathers who will feel as I do, after reading Sir Michael Foster's address, and I venture, therefore, to ask for a little information. A middle-class man with a fairly large family of boys, most of whom have done fairly well—generally after wriggling their round selves out of the square holes into which I had fitted them, I want to know how I could start the youngest, a boy of 16, of average intelligence, but no special bent, and educated at one of our second-rate public schools, in some career in which he might work for science and—earn a modest living?

It is possible that some of your readers who have been through the mill may give hints. They would, I feel sure, be welcomed by many well-meaning parents. I am not pleading for facilities for the embryo giants of science. Their abilities will find recognition and encouragement, like those of Faraday and many others have done in the past. I only ask, in the first place, how it is possible to start average lads in the pursuit of some branch of scientific work which shall yield bread and cheese, and the prospect of really benefiting their fellows, instead of robbing them; and, next, is it not time the British Association, or some other organisation, devoted attention to, and sought means for the establishment of facilities for accomplishing this end? **Kappa.**

AHAZ'S DIAL.

[42822.]—BOTH "Little Bookham" and Mr. Wilmay, on p. 92, may be quite positive they are wrong about Isaiah's miraculous prediction of the shadow going back on the dial. It was a rare atmospheric effect that I had the good fortune to see reproduced at Portsea on 29th of March, 1848, and in the *Philosophical Magazine* of that June, p. 434, they will find my description of it. But the fact of its involving the same occurrence as that of Hezekiah's time was quite unknown and unsuspected by me till after 1860.

The cause of this phenomenon, called *parhelia* or *mock-suns*, and in some parts of England *sun-dogs*, is a state of the air filled with crystals of ice, like microscopic prisms; and when these have their axes turned in all directions indifferently, the effect is comparatively common, being merely a bright circle of 22½° radius round the sun or moon, called a halo. But when some electrical condition of a still atmosphere causes all or most of these prisms to be turned up vertically, several other circles appear, and at their intersections bright spots called mock-suns, of which there were six at Portsea. Most of these were far too faint to cast shadows; but there were two dazzlingly bright that concentrated all the light of a halo into two parhelia, right and left of the true sun, at his own altitude, and distant from him just a quarter of a quadrant. Now clouds floating about the lower air might hide either of these, or the true sun. If the sun and eastern parhelion were hidden, the western would cast shadows in the position the true shadows would have one hour and a half later. But if the true sun and western parhelion were hidden, the eastern would cast shadows such as the true sun cast one hour and a half earlier.

The phenomena were only perfect when the sun was at a certain altitude. I saw them first at 11 a.m., but afterwards at 1 p.m. for a longer time. Hours are not mentioned in any book earlier than Daniel; but the distance between the true sun and a mock sun being always a quarter of a right angle, if this quadrant was divided into 40° (a favourite number with the Hebrews), Isaiah could be ordered to offer Hezekiah the choice, Shall the shadow go forward 10°, or backward 10°?

As everyone connects this event in some way with Joshua's supposed miracle of stopping the sun and moon, I would here add that no such thing ever happened, or was related in any Scripture. First, the Samaritan book of Joshua notes nothing of the sort, though it relates the battle at greater length than the Hebrew book. The Samaritan's Bible consists only of the Pentateuch and this book of Joshua, which is not only much longer than ours in the part relating to Joshua, but adds brief accounts of all the chief political conquests of Palestine, down to Titus's conquest, the book not being finished till his time. Next, the New Testament has no reference to this miracle (even in Hebrews xi.), though the Son of Sirach believed in it, and monks have even believed repetitions of it as late as four centuries ago. In an account of the funeral of St. Peter of Alcantara, they had long ceremonies, and were astonished to find the sun not yet setting.

But there *was* a miracle at Gibeon, which was thus related. After the storm of hail had defeated the Amorites, and "they were more that died with the hailstones than they whom the children of Israel slew with the sword"; then spake Joshua to *the Lord*, "and He (the *Lord*) said in the sight of Israel, Sun of Gibeon, be silent, and thou moon of Aijalon Valley." And the sun was silent and the moon silent, until the nation had covenanted with their enemies. Therefore it is written in the Book of Jashar, "and the sun stayed in mid-heaven, &c." But the *Lord* said nothing about the sun in heaven, but the sun in Gibeon. The idolatrous Gibeonites had two oracular temples in Gibeon and Aijalon, but they had entrapped the Israelites and Joshua into a treaty of friendship (Chap. IX) No violence then could be used against them, and without a miracle, these heathen temples must always have stood. The *Lord* commanded this sun and this moon to be silent. The quotation from the Book of Jasher (or of the Upright) was not to cite it as authority, but to show why it was rejected. It was written after David's time, and never accounted Scripture. The silencing of these oracles was miraculous, because nothing in history is more certain than that oracles did exist in heathen countries. Such men as Crœsus and Cæsar would not have believed in mere frauds. Miraculous predictions were uttered by mediums (as we should now call them) in the names of the Sun, Moon, and various gods; but never later than our Lord's birth. Now, Joshua was a notable type of Him. His name ultimately became Jesus. It is most proper, therefore, that he should occasion the ceasing of these oracles; as afterwards, at our Lord's birth, all the oracles were silenced.

The division of a circle or a quadrant into 40 parts, as the Hebrews of Hezekiah's time divided it, can be done by compasses, with about four openings; whereas our division into 90 cannot be done geometrically at all.

Sept. 8. **E. L. Garbett.**

[42823.]—MANY thanks to "Wilmay" (letter 42797), but I do not think that the return of the shadow on the sundial of Ahaz can be explained by the occurrence of a partial solar eclipse, which would hide the upper portion of the sun's disc. Hezekiah's illness is fixed by Demetrius as having occurred about the time of such an eclipse, which happened on Jan. 11, 689 B.C., at 11.30 a.m. My Bible dates the incident 712 B.C. The prophet Isaiah would have foreseen an eclipse, and the whole affair would have been no miracle, but a neat fraud. Now what would happen if the South Magnetic Pole was moved a thousand miles nearer the North Pole? The question does not entangle the Southern Pole of the earth's axis of rotation, or the experiment would fail; and also what is the meaning of Revelation x. 6: "That there should be time no longer." What antics would the shadow make in this condition? We do not want another Deluge, but a reversal of the process.

Little Bookham.

THE NUMBER 666—THE DELUGE.

[42824.]—WILL Mr. Garbett tell me whether the original of the word in Daniel viii. verse 25, which is translated *prosperity* in the margin, bears the same meaning as Ευχορία? If so, it has some bearing on his contention, which, however, he must forgive me for saying, he seems to be running to death. Will he contribute an article dealing with the geological indications of—(1) a deluge such as described in the Bible, (2) the existence of a lower sea level in ante-Silurian times—such, for instance, as the 600ft. deep cliff line mentioned on p. 92? If he would do this, giving references to authorities for otherwise *ex cathedrâ* statements of fact, it would be certainly of interest, and probably instructive. **Glatton.**

MICRATOMIC ETHER.

[42825.]—REFERRING to a few of "G. M. W.'s" statements, I should like to say a few words. In the first place, he says that the all-pervading ether is not matter, because it has none of the properties of ordinary matter. Let me ask him what properties water has in common with a mixture of oxygen and hydrogen, which it does not share with other elements and compounds. Light is energy, as is shown by the photometer and other instruments. Can energy be transmitted through a void, a vacuum of all matter? Decidedly not, and yet light is transmitted from the sun to the earth.

Magnetism is, and it can be proved quite easily, an ethereal disturbance, and that disturbance is energy. Other energy is consumed when iron is magnetised. If iron is attracted, you get mechanical energy; but you lose some magnetism.

Electricity in a current, as far as I can see, is a molecular disturbance, accompanied by an ethereal disturbance. Can anyone kindly explain how it is that these two disturbances are always in the same proportion to each other? Magnetism retains only the ethereal energy. Secondly, he tries to point out that it is against the laws of nature for an element to combine with itself, as would be the case if all matter were built up of micratomical ether; but do not two atoms of oxygen *combine* to form one molecule?

If "Lucretian's" theory be not correct, how can the periodical arrangement of elements, according to their atomic weights, be accounted for, and also the relations between atomic weights of elements in the same group?

Is not the difference between, say, Australian and Californian golds due to atomic and not molecular differences, and would not this tend to show that the difference between various atoms was only one of degree? I think that if "J. M. W." considers what I have said he will agree with "Lucretian" on some points.

To R. A. Kenedy: Is not the pitch of sound equivalent to the colour of light? **W. Howse.**

MOTOR CYCLES.

[42826.]—I BEG to draw your attention to a slight error with reference to the above articles. In Aug. 4th issue, bottom of first column, p. 542, driving-wheels are given as 26in. dia. In Sept. 1st issue on general arrangement of tricycle, driving-wheels measure 30in. dia. Would the writer kindly say which is correct in paper?

An Interested Reader.

[42827.]—"THE WRITER &c." asks me (p. 41, 42735) what are my objections to flanges on a brake-drum? It seems to me that they entail needless weight and work, and diminish the available brake surface. For instance, the brake on the differential of the Decauville consists of two ½ bands, with a flange between them, and are on each side. If these were absent, and a single band used (which would be better than two narrow ones), there would be about ⅜ more driven surface available. There is also a certain amount of friction against the flanges, tending to draw the brake on, and they make it difficult to adjust the band so that it does not rub against the drum when "off," a common fault with band-brakes, especially if weakened by many rivets.

I have ridden many tricycles with band-brakes, but cannot remember any with flanges. I think it would be an improvement to fix the band by its centre, it being either tapering in thickness either way from the middle, or made of two superimposed leaves of unequal length, like a carriage spring, and strong enough to fly open when released, so as to form its own spring, the ends being drawn together by a double-acting lever, as in the "Writer's" drawings. It would then not only act either way, but would be much less likely to bind than the usual pattern. The spring used to release a brake should be close to the latter—not close to the handle, as some makers put it. This prevents rattle in the joints of the brake-rods, for it keeps them all pulled tight in the same direction as they are when the brake is applied. **Faber.**

[42828.]—I BEG to call "The Writer of the Articles'" attention to what I think is a slight mistake, which appeared in last week's issue on

p. 78. In the description of Fig. 106, at the bottom of the third column, you say: "The thin lines are the primary wires, and the thick the secondary." Now, according to both the diagram and also the succeeding explanation, the *thick* lines are the *primary*, and the *thin* are the *secondary*. I hope you will pardon me for making known this mistake.

A. Drysdale.

MOTOR-CARS.

[42829.]—I HAVE been very much interested in the articles and correspondence appearing in your paper relating to the Motor Cycle.

I think it might help the writer of the article, "R. J. V.," to unravel the mystery of the long cylinder bolts, to know that I came across a Loyal petrol motor with them; but I do not know if it was made before the date of the De Dion Patent, which is No. 19735 of 1895. Can the writer of the article, "Monty," or any of "Ours" tell me if there are any patents on the Benz motor-car, as I hear The British Motor Co. claim to have some rights on this car?

H. C.

BOILERS FOR MOTOR-CARS.

[42830.]—I AM much obliged to Mr. Allison (42792) for his reply to my letter on the above subject, and would like to have further information, if not too much trouble. I am not quite clear whether it is to be vertical—i.e., with the end plates on top and bottom or horizontal, as it appears to be by the drawing. And will not coal do with it, as oil-burners seem to be costly and complicated? Also has it been tried and found practicable? I hope Mr. Allison will forgive my troubling him again, but I believe there are many others besides myself who would be glad of information.

Water Tube.

BOLLEE MOTOR-CAR.

[42831.]—I HAVE been much interested in the articles running in the "E. M." on the construction of a motor tricycle, and should be glad to know whether an article will follow on the construction of a small motor-car on the Bollée style. There must be a good number of readers who would like to make such a machine, so that they could take out their wives with them for a spin, and to such I think the articles would be a boon. I have mentioned the Bollée pattern because this seems to be the simplest type to make. If the author of your articles cannot see his way to give a series of articles, would he kindly inform me where I could obtain working drawings, and also, if possible, where reliable castings may be obtained?

Machinist.

PRINCIPAL AND INTEREST.

[42832.]—I AM afraid I do not yet understand Mr. Garbett's views on the subject of capital; but I presume he repudiates the theories of Mr. Henry George, to which I chiefly referred. Demetrius was evidently an employer of labour, and probably a capitalist, to the extent of purchasing the silver required for his purpose and providing the means of working it. But whether he paid wages to his workmen, or gave them a share of the profits, does not appear. Indeed, he rather speaks as if the Ευπορία was theirs as well as his. If so, I hardly see the point of Mr. Garbett's Mark of the Beast. And then what became of capital during the time that elapsed between Demetrius and Franklin? Or why is Franklin singled out except for kite experiment, which had nothing to do with Ευπορία?

As to the talents and the pounds, did not the servants in both instances (except the unprofitable servant) use the money as capital, and are they not commended for so doing?

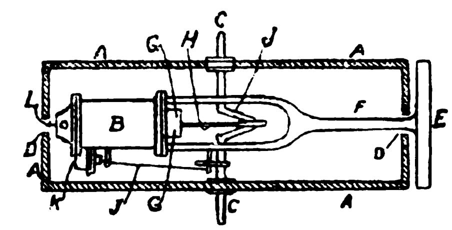
Moreover, lending money at a fixed rate of interest is not the way to acquire great wealth. The interest at the present day will be very low unless the investment is of such a character as to involve risk to the principal—as, for example, preference shares or debentures in some concern that may fail and pay nothing. Men who have realised great fortunes, and either retained them or lost them again, have always adopted different modes of acquisition from lending at a fixed rate of interest. Indeed, in the latter case the borrower, rather than the lender, acts the part of the capitalist. It is the borrower who employs labour, makes a profit, and pays the interest out of his profits. I think your readers will hesitate before finding the mark of the Beast in the forehead of every person who has a few pounds at a fixed rate of interest in a Post Office Savings Bank.

I fail to see why a landlord is to be regarded as a capitalist. In any event, when the intended tenant comes to take the land, he can (in a country where there is free contract) make his own bargain. He can purchase part of the land out and out if he has the money and the landlord is willing to sell. He can agree to pay a definite proportion of the produce, or a fixed rent, or a fixed portion of the produce, or a rent varying with the price of farm produce, or a rent below the estimated value together with a fine. If fixed rents are more common, it is probably because both landlord and tenant find them convenient. A rent consisting of a fixed portion of the produce is common in France. Has the system such an advantage over ours that we can find the Mark of the Beast in the one but not in the other? If Mr. Garbett was merely arguing for an extension of the co-operative system, I should not be disposed to quarrel with him; but I think co-operative societies would often find it very inconvenient to be deprived of the power of borrowing money at fixed rates of interest.

W. H. S. Monck.

A SMALL ENGINE.

[42833.]—I AM sorry Mr. Haig (letter 42764) does not understand Mr. Gibson's sketch. He thinks 99 per cent. will be in the same position. Perhaps the accompanying sketch may help him. I must be



A, flywheels; B, cylinder; C, axle; D, edge of rim of flywheels; E, standard bed-plate; F, standard supporting-engine; G, piston; H, connecting-rod; I, crank; J, slide-valve or ignition controlling-rod; K, valve-case; L, exhaust.

No. 100 per cent., as I see what Mr. Gibson means. Will Mr. Gibson please say if sketch and explanation are correct? I think this engine would work well.

A Drysdale.

[42834.]—I DO not wonder at Mr. Haig (letter 42764) being unable to understand my sketch, as it has been printed lying on its side. The flywheels inclose everything except the bottom of the column.

Also in my reply No. 96501 there has evidently been something omitted. I meant correspondent to understand that although most of the sizes would do, it would be advisable to strengthen others.

W. Ewart Gibson.

A MODEL ENGINE.

[42835.]—THE sketch of Mr. Gibson's has several uncommon points about it. The design shown would, I think, do very well for a model engine, but would, of course, be of no use for, say, a ½B.H.P. engine and upwards, because the moving parts are too much out of sight and inaccessible. Personally, I always like to be able to feel the bearings of an engine when running if they get hot, and oil them, which, of course, in Mr. Gibson's design, is out of the question. The best compromise would be to make the flywheels with three or four arms instead of solid, unless one or both flywheels were made detachable. The bedplate is of unusual form and light. I have often wondered why oil-engine makers stick like wax to the heavy cast-iron foundations for launch engines where weight is so important. Yes, I know oil-engines are single-acting, and want a firm foundation. Girder frames and cast steel rockers are now very fashionable for passenger steamers, fast fruit boats, &c., where they save a lot of weight and give satisfaction. All new Government warships, from the biggest ironclad indicating thousands of horse-power, down to the smallest launches, are built on this principle. I have worked on them. So why not oil-engines? Where G. A. Haig's (page 67) difficulty in understanding the sketch comes in I don't see. Two flywheels as described, anyone, who has done any drawing, can see with half an eye.

O. G. A. P.

STEREOSCOPES.

[42836.]—YOUR correspondent of Aug. 25 tells us how to see stereoscopic views without a stereoscope, and instructs us to do it by converging the eyes—which means, in plain English, by an inward squint. May I be allowed to point out that squinting inwardly does not produce the true stereoscopic effect, because the vision crosses, so that we see with the left eye the picture that we ought to see with the right, and vice versâ, the result being a sort of reversal of the perspective—curious with geometrical figures, but false and quite unnatural with ordinary views. To get the true stereoscopic effect it is necessary to squint *outwards*, just enough to bring the two pictures into one. This is by no means such an easy feat as the other, and I cannot do it myself; but I have seen it done by an accomplished photographer, who habitually tests his stereoscopic work in this way. To make sure that you are squinting outwards it is necessary, at the outset, to place a partition between the eyes reaching from the nose nearly to the line between the two pictures. Possibly many have the power of squinting outwards at will, but it does not strike me as a very wholesome exercise to squint either way—for young people, at all events.

R. S. D.

LEGAL REMEDY.

[42837.]—IF "Hear Both Sides" can point out any mode of recovering money from a person who has not got it, he will confer a benefit on the community. As to costs, which are not allowed against the other side, I think most readers will admit that if a litigant will insist on having almost daily conferences with his solicitor about the progress of the case, on retaining two or three of the most eminent counsel that can be procured, and, generally, on incurring heavy expenditure, with a view of "making assurance doubly sure," it would not be fair to onerate his opponent with the whole of the costs thus incurred, more especially if he only succeeds in establishing a part of his demand. Many writers on the subject write as if the case was transparently clear. If so, would not one or two interviews with the solicitor and one counsel at the trial be sufficient? Heavy expenditure usually means that the case is not clear, and, as already intimated, the success is perhaps only partial. If I demand £100 and am awarded £50, is it fair that my opponent should have to bear all the costs incurred by both sides?

W. H. S. Monck.

USEFUL AND SCIENTIFIC NOTES.

A DAM is to be constructed by the Great Falls Power Company, across the Potomac, at the Great Falls, together with a canal to convey the water to a power-house some distance below the dam.

THE following are the principal dimensions of a type of compound locomotives made by the Baldwin Company for the Erie Railroad. The engines have a total weight of 67½ tons, with a stroke of 26in., and 13in. and 22in. cylinders. The driving-wheels are 76in. in diameter, and the working steam pressure 200lb. Other particulars are as follows:—Tubes: Number, 271; material, iron; outside diameter, 2in.; length, 15ft. Fire-box: Length, 96in.; width, 96in.; material, carbon steel. Tank capacity, 6,000gals.; coal capacity, 8 tons.

ACCORDING to an American contemporary, the maximum spans possible for wires of different materials on a basis of a factor of safety of four is as follows:—Cast-steel wire, 3·42 miles; silicon-bronze, 1·56 to 1 mile, depending on quality; wrought iron, 1·02 miles; and soft copper, 0·53 miles. These maximum spans, it is said, are independent of the cross-section of the wire, for although the weight of the wire increases with the cross-section, its strength increases in the same proportion. The spans given do not allow for wind-pressure, snow, or ice.

Indiarubber.—The constantly-increasing importance of indiarubber renders of peculiar interest the experiments which have been made by the Asam Forest Department on the cultivation of *Ficus elastica*. According to a correspondent of the *Field*, the initial attempts to start successful plantations all resulted in failure, and it was not until 1879 that any success was attained. At the outset an attempt was made to imitate Nature by planting the seeds in clefts of trees, in the hope that the *Ficus* might, in germinating, become epiphytic on its host, but failure was the result. Planting cuttings was next resorted to, but though these struck readily, the resulting tree was almost devoid of aërial roots, which are an important factor in its after-life. In the end, the plan was adopted, and has succeeded, of raising the plant from seed and transplanting it as its stage of growth requires. Thus, the seedlings, when 2in. to 3in. high, are transplanted to nursery beds, where they are inserted in ridges about 1ft. apart, and remain here till a height of 12in. is attained. Each plant is then transferred to a bed 5ft. square, where it remains till a height of 10ft. to 12ft. is reached, having in the mean time been protected by fences from injury by animals. At this stage of the growth, the final transplantation is made. The roots being cut back to within 18in. of the stem, the tree is dug up and transferred to its final resting-place in the forest, and when an age of twenty years is attained will be ready to tap. The capital outlay is not large, but the money expended being locked up so long is a drawback; still, the plantations which have now reached the tapping stage are showing an excellent return on the original outlay, which amounted to £4 9s. 3d. per acre. The net profit, on the other hand, after paying expenses of collecting the rubber and freight to London has been £2 3s. 7d. per acre.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96373.]—**No Dead-Centre (U.Q.)**—In an ordinary single-cylinder engine the dead-centre is overcome by the momentum of the flywheel. If the querist has an invention which does away with the dead-centre, he would in all probability dispense with this wheel, which, up to the present time, has been looked upon as a vital necessity in single-cylinder engines; and although this is an inventive age, it is very doubtful if it will ever be supplanted—certainly not by any additional mechanism, the increased friction of which would lessen the effective power of the engine without yielding the other advantages which the flywheel possesses. MARLBOROUGH.

[96418.]—**Balance Gear.**—This query does not appear to have anything to do with balance gear, but rather with the methods adopted to get railway wheels round curves. Driving wheels fixed on an axle cannot revolve at different velocities; but the tires are coned, and the wheel on the outside of the curve covers more "ground" than that on the inside of the curve. There are plenty of manuals which explain this matter; but there are certainly not any ratchet-wheels on the axle, if a locomotive is meant. There cannot be any "fog" about the matter. The subject of coning railway wheels has been thrashed out years ago. MOTION BAR.

[96423.]—**Filtering Water.**—For an illustration of rainwater separator, see p. 379, June 9 last, and look as far back as 1870. What is wanted is a tilting arrangement which will (after the roofs and pipes are washed by the first of the rain) turn the following water into the butt or tank. There should preferably be two butts, in the upper of which the rainwater can be filtered into the lower. The late Shirley Hibberd had an excellent one fitted up at his house in Lordship-lane, Stoke Newington. Look through the back volumes if the device shown in the number for June 9 does not suit. M. T.

[96468.]—**Indiarubber Stamps.** — "Regent's Park," in his answer, says a dentist's vulcaniser is used for this. Really it is altogether the wrong thing. He says the mass is to be poured over the type. What mass is it? He says the stereotype plate is not to become dry, but is laid on a plate of vulcanised caoutchouc. The fact is, the mould must be thoroughly dry, and the rubber must be the *un*vulcanised. He gives 305° F. for curing heat, which is only suitable for making hard rubber; the soft is cured about 290°. He gives a long method of rectifying alcohol to mix with carbon disulphide as a solvent for rubber, whereas the carbon liquor dissolves pure rubber easily. With these few exceptions, his answer is not very far incorrect.
West Didsbury. M. COLE.

[96471.]—**Loan Amortisation.**—I have not one original question of "X.'s" to refer to now, but have before me his elaborate tables at p. 71. He thinks that the loan to be extinguished on one "amortisation" principle, as illustrated in the first table, is more favourable to the borrower than the loan as treated in the second table. Truly, that is so, as the first loan is at the rate of 3½ per cent. interest, and the second one at 4½ per cent. "X." will perhaps understand better if he looks at the matter from the lender's point of view. He lends £1,000 to pay himself at the rate of 3½ per cent.; repayments to be made in 44 annual equal payments of £45 each, to include interest and principle. Out of each annual £45 he puts £35 into his pocket, as and for 3½ per cent. interest, and the remaining £10 annual surplus he reinvests at the same rate—viz., 3½ per cent., which, with compound interest, will amount in 44 years to £1,000, which is the recoupment of his lent capital, so that £35 per annum is interest at 3½ per cent., and £10 per annum (total £45) is the annual sinking fund to be improved at 3½ per cent. compound interest to repay the £1,000 loan at end of 44 years. The second table shows the same annual payment £45, but states that the rate of interest is 1 per cent. more—viz., 4½ per cent., so that the £45 per annum is entirely absorbed by the interest, leaving no surplus to be reinvested to replace the capital. The equal annual repayment for 44 years for a loan of £1,000 at 4½ per cent. would be £59 6s.—viz., £45 for interest, and the surplus £14 6s. to be reinvested to accumulate at 4½ per cent. compound interest to replace the capital. As to the building society case of a loan, £1,000 to be extinguished during 20 years by 240 monthly payments of £7 each, that would be nearly at the rate of 7 per cent. For instance, if we treat it as 20 annual payments of £84, those payments would be worth in present money, to pay a purchaser 7 per cent., £1,011. Of course, 12 monthly payments would be worth a little more than one yearly payment, so that the percentage to to be returned by purchasing 240 monthly payments, instead of 20 yearly payments which £1,000 would purchase, would have the effect of increasing the interest which the purchaser (in this case the building society) would receive. There are other complications—e.g., the calculation may be made on the footing of pocketing one rate of interest and reinvesting the surplus to replace capital at another—a lower and more available rate. But if "X." desires to better understand these and similar questions, he cannot do better than first make himself acquainted with the use of logarithms, and study "Inwood's Tables," or, preferably, "Biden's Valuation Tables," and "Biden's Practical Rules for Valuers"—these last two out of print, but may perhaps be borrowed—and he should not omit to peruse "Compound Interest and Annuities" by Fedor Thoman, who treats largely of amortisation. "X." will perceive that the third column of his table is (or should be, if correctly calculated) £10 per annum improved for 44 years at 3½ per cent. compound interest, and that it will total to £1,000. Thus the first amount is £10, the second sum is £10·35; that is, the second annual £10 with interest at 3½ per cent. on the first £10 added; the third figure is £10·71, which is the third annual £10 with interest at 3½ per cent. on the sum of the two previous figures—viz., £20·25, and so on. It is an increasing series, each term augmented by the addition of £10, plus interest at 3½ per cent. on the sum of the preceding terms. A. H.

[96471.]—**Loan Amortisation.**—In "X.'s" original query it is stated that "£1,000 is borrowed *at 4½ per cent. interest*, the capital to be paid out of the interest in 44 years by a sum amounting to £1967·57." This is impossible. If we borrow £1,000 at 4½ per cent., and at the end of each succeeding year pay £45, our indebtedness will remain as at first. It is quite obvious, therefore, that if we pay *less* than £45 yearly, our indebtedness will increase; and if we pay more than £45 yearly, our debt will gradually decrease, and ultimately vanish. The more we pay over and above the £45, the sooner we shall be free. If, however, we take "X.'s" query with its supplement (p. 71), we perceive the fact is that £1,000 is borrowed, to be repaid by annual instalments equal to 4½ per cent. of the original loan. This is quite a different thing to borrowing at 4½ per cent. interest. The loan is, according to his own showing (supplement), borrowed at 3½ per cent. But as the repayment chances to be 4½ per cent. of the loan, the querist has got a bit mixed. The amortisement, or sinking fund, is created by the borrower when the lender is averse to receiving back his principal in driblets or annual instalments. In this case it is £10 yearly, the difference between the yearly repayment and one year's interest of the original loan, 45 − 35 = 10, and £10 invested at the end of every year for 44 years at 3½ per cent. will amount to £1,000, wherewith to repay the loan. It very frequently happens, however, that the sinking fund has to be invested at a lower rate than that paid for the loan, then either the sinking fund must be increased or the time extended. In this case, if the sinking fund could only be invested at 3 per cent., then it must be—

$$\log. 1{,}000 = 3\ 00000$$
$$\log. a = 8\ 61521$$
$$\log. R^{-n} = 9{\cdot}43516$$

$$\log. S = 1\ 05037$$
$$S = £11{\cdot}23,$$

instead of £10, thereby causing the repayment to be £46·23, instead of £45. The time required at 3½ per cent. is not exactly 44 years—more correctly, 43·642. In answer to his further query, p. 71, with the aid of monthly logarithmic tables, compiled some years ago, I make the interest in the building society transaction 5·714 per cent., and the monthly sinking fund £2·2383. GARSDALE.

[96478.] — **Poultry.** — When Mr. Turner has caught the sinner, let him, with a sharp knife, pare the upper portion of the bill till it is but very little longer than the lower. This remedy is effectual with egg-eaters also, and in both cases is always adopted by GARSDALE.

[96515.]—**Model Steamer.**—Boiler of locomotive will do for steamer described; but it will not be easy to keep up enough steam for at all a long run. Certainly, put another tube through—two more, if there is room. The single-action oscillators are very wasteful of steam; much better fit one slide-valve instead. A second safety-valve is not absolutely necessary, but it is always advisable. A piece of knitting-needle, or bicycle-spoke, makes a good propeller-shaft. Make it as short as possible; not more than 5in. Let it run in a tube nearly as long as itself, with brass bush at each end. Fill tube with vaseline, and it will be perfectly water-tight, besides lubricating the shaft. A powerful lamp, which will go on burning for some time, and will not cause conflagration, is to be desired. I will send sketch of one I fitted to a boat some years ago, which went very well, if querist wishes.
No. 7.

[96521.]—**Speed of Falling Chain.**—In my previous note I showed how the falling chain gradually attains its limiting velocity $v = \sqrt{g h}$. In the issue of Sept. 8 "P. B.," employing the principle of the conservation of energy, arrives at the conclusion that the speed of the chain is $v = \sqrt{2 g h}$. But "P. B." has fallen into error, because he has not taken account of all the forms in which the potential energy reappears. The application of the principle of the conservation of energy to mechanical problems always requires the greatest caution. The present problem affords an excellent illustration of the need of caution. If m be the mass of unit length of the chain, and h be the distance through which the chain descends, then the work done by gravity on the chain per unit length is $m g h$. The kinetic energy of the chain per unit length is $\frac{1}{2} m v^2$. This kinetic energy is "destroyed," so far as mechanical effect is concerned, by the impact of the chain with the ground. The energy, of course, is not lost; it appears as heat. The top of the chain has still to be considered. Here each link is started suddenly; at one instant it is at rest, and at the next instant it is moving with the velocity v. The process is, in fact, the exact reverse of that occurring at the ground, and thus it may be foreseen that heat will be produced at the top of the chain at the same rate as at the bottom of the chain. A detailed examination will make this plain. The momentum of unit length of the chain is $m v$, and v units of length are started per second. Thus $m v^2$ units of momentum are given per second to the chain by the tension at the top of the chain, and hence $m v^2$ is the measure of that tension. The work done by the tension while unit length of chain is uncoiled is $m v^2$; but the amount of kinetic energy taken up by this unit length is only $\frac{1}{2} m v^2$. The difference, $\frac{1}{2} m v^2$, is the amount of mechanical energy which has been converted into heat. Since the chain is supposed to have acquired its limiting velocity, the kinetic energy of the part of the chain actually in motion is constant. The work done by gravity must therefore find its equivalent in the heat produced at the top and at the bottom of the chain. Thus we have $m g h = \frac{1}{2} m v^2 + \frac{1}{2} m v^2$, or $v = \sqrt{g h}$. G. F. C. SEARLE.
Calshot House, Ryde.

[96521.]—**Speed of Falling Chain.**—Mr. D. J. Carnegie finds correctly that the acceleration of the falling chain is $\frac{g}{3}$ before the lower end reaches the bottom of the pit. It is not true, however, that after the lower end has reached the bottom of the pit, the velocity remains constant. If h be the vertical distance between the platform on which the chain is coiled and the bottom of the pit, the differential equation satisfied by the velocity of the chain, at any time after the end has touched the bottom of the pit, is—

$$v^2 + h \frac{d v}{d t} = g h \text{..............(1)}$$

The solution of this equation is—

$$v = \sqrt{g h} \cdot \frac{C e^{2 t \sqrt{\frac{g}{h}}} + 1}{C e^{2 t \sqrt{\frac{g}{h}}} - 1} \text{ ....(2)}$$

when C is a constant. If the time is reckoned from the instant when the end of the chain touches the bottom of the pit, and if the chain be supposed to have started from rest originally so that the velocity at the instant of contact is $\sqrt{\frac{2}{3} g h}$, then the value of C is found to be—

$$C = -\frac{\sqrt{3} + \sqrt{2}}{\sqrt{3} - \sqrt{2}} = -9{\cdot}8988 \text{ ......(3)}$$

and thus—

$$v = \sqrt{g h} \cdot \frac{9\,8988 e^{2 t \sqrt{\frac{g}{h}}} - 1}{9\,8988 e^{2 t \sqrt{\frac{g}{h}}} + 1} \text{ ....(4)}$$

After an infinite time $v = \sqrt{g h}$, as may also be seen by putting $\frac{d v}{d t} = 0$ in (1). Thus the velocity of the chain, after the lower end touches the ground, increases from $\sqrt{\frac{2}{3} g h}$ to $\sqrt{g h}$; these velocities are those of a freely falling particle which has descended from rest through distances $\frac{1}{3} h$ and $\frac{1}{2} h$ respectively. To find the amount of chain paid out in any time it is necessary to integrate the expression (2). The length of chain paid out since the end has reached the bottom of the pit is thus found to be—

$$x = h \log. \left(\frac{C e^{2 t \sqrt{\frac{g}{h}}} - 1}{C - 1}\right) - t \sqrt{g h}.$$

When t is large this takes the form—

$$x = t \sqrt{g h} - h \log. \left(1 - \frac{1}{C}\right)$$
$$= t \sqrt{g h} - {\cdot}0964\, h$$

with the value of C adopted above.
Calshot House, Ryde. G. F. C. SEARLE.

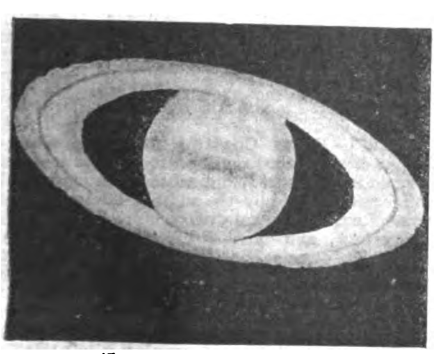
[96526.]—**Fly Catchers.**—Strong solution of

white arsenic (say 1 drachm to the pint) sweetened with moist sugar, molasses, or honey. Molasses, honey, moist sugar mixed with one-twelfth their weight of king's yellow or orpiment, very poisonous. Quassia chips ½oz., water 1 pint, boil ten minutes, strain, and add molasses 4oz. Black pepper 1 teaspoonful, cream 4 teaspoonfuls, brown sugar, 2 teaspoonfuls, mix with sweets. Fly-paper: Quassia wood ¼lb., water 1 quart, pour water on wood and allow to stand over night. Strain and boil liquid down to one pint; boil wood again with one pint of water until half-pint remains. Mix the two infusions, add ¼lb. sugar. When the sugar has dissolved, pass the paper through the liquid, drain, and dry free of poison. Or oil paper with turpentine varnish; or quassia chips 150, chloride cobalt 10, tartar emetic 2, tincture of pepper (1 to 4 proof spirit) 80, water 400; or pour a little simple oxymel into tumbler, place in glass a piece of cap paper, made into shape of upper part of a funnel, with hole at bottom to admit flies; smell attracts them, and they readily enter; or take earthenware pot, half fill with soapy water; cover with piece of paper, tied down or tucked under rim. Rub paper inside with wet sugar, molasses, honey, or jam, cut small hole in centre for fly to enter; fly settles on top, crawls through hole, warmth of weather causes soapy water to ferment, produces gas overpowering fly. REGENT'S PARK.

[96539.]—**Ebonite Boxes.**—In this reply on p. 95, what is meant by "resin," or is there some error? There are several resins, but I suspect that rosin is the substance meant; if so, why not say so? Many of these replies are useful when understood, no doubt; but it takes a good deal to understand them, and as it seems useless to appeal to the writer for the requisite information, I must ask readers generally. N. S.

[96546.]—**Motor Batteries.**—Mr. Saurez states in above query that he ran 500 miles by means of his De Dion quad motor. May I ask for a little information as to the character of construction of the above-mentioned motor, and how propulsion thereby is perfected, and the weight of same? The dry batteries spoken of are, I presume, for the purpose of ignition, not as a means of propulsion of tricycle. Kindly give dimensions of cells and the number required, also the price of motor. PHOTO.

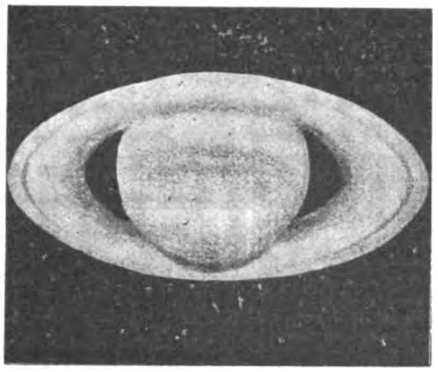
[96547.]—**Saturn.**—In spite of its low declination, I have had several splendid views of Saturn, especially on July 8th, when the definition was excellent and quite steady, allowing me to employ a power of 170 on my 3·1in. refractor. It was a splendid sight, but nothing abnormal was to be seen. The N. polar region appeared distinctly shaded. There was a broad and easily seen dusky band crossing the ball at about the centre of the



disc. The shadow of the crape ring on the ball could be faintly seen. The outer ring appeared distinctly dusky, and its outer edge was diffuse. The inner ring was bright and sharp. Cassini's division could be traced a long way round both ansæ. I have been obliged to heighten the contrast in the sketch for purposes of reproduction.

Trin. Coll. Oxon. J. M. W.

[96547.]—**Saturn, 1899—The Ring Nebula—A Large Magnet.**—The accompanying drawing may give some idea of the appearance of Saturn at the time of last opposition, June last, when opportunities of getting good views were less infrequent than lately. Good definition could never be bad; but, on one occasion, at any rate, powers of 100 and 200 were borne for a very short time. The broad duplicate belt to the N. of the equator was always seen, even in the poorest air, and is an easy feature. I wonder if any reader can give me some idea of the magnitude of the star immediately following the Ring Nebula? It is quite an easy object with any 5in. mirror, but appears in former years to have been of 14th magnitude, if we can take the observation recorded in Webb as correct. It is considerably brighter than the minute stars between ϵ_1 and ϵ_2 Lyræ, which are about the *min. vis.* of my instrument. The large magnet referred to by "F.R.A.S," formerly owned by Lord Lindsay, and now in the Royal Observatory, Edinburgh, is hardly, I think, so powerful as he suggests. A bunch of keys requires to be held fairly close to the poles before they will fly towards them. An iron bar placed

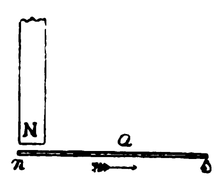


upon the poles, however, requires very considerable force to remove it. CHARLES F. SMITH.

[96549.]—**Encke's Comet.**—I am thankful to "F.R.A.S." for his confirmation of last perihelion passage on May 24th, 1898, but my object was to get a nearer approximation. J. R. Hinde, in "Comets" (Ency. Brit.) gives the perihelion passage 1875, April 13 0682, and I was in hopes some of "ours" could supply a like fraction to the date I gave. W. S.

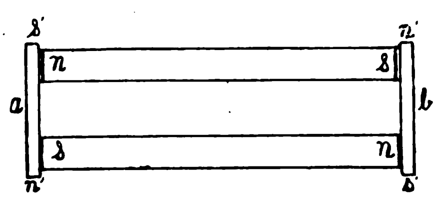
[96552.]—**Cigarettes for Asthma.**—Tobacco 90 grammes, extract stramonium 5 grammes, iodide potassium 5 grammes, nitrate potassium 5 grammes, alcohol 45 grammes. Mix, dry, and make a hundred. Use small hand machines, sold everywhere. REGENT'S PARK.

[96554.]—**Magnetism.**—Either a horseshoe or bar-magnet may be used, according to whichever is most convenient. For magnetising a compass-needle a bar-magnet might do better. The simplest method is that of single touch as in sketch. If a



a, Compass needle; N, North pole of magnet; *ns*, poles of needle. Rub pole of magnet a few times along needle in the direction of the arrow. Repeat on other side.

straight bar-magnet is laid away by itself alone it loses its magnetism. Bar-magnets should always be put away in pairs, with opposite poles adjoining, and connected by small pieces of soft iron laid



ns, ns, Poles of bar magnets; *a b*, keepers; *n' s'*, *n' s'*, induced poles of keepers.

across the poles as keepers. The keepers are magnetised by induction, and react upon the magnets and so preserve their strength. See sketch. A. DRYSDALE.

[96556.]—**Oil- and Gas-Engines.**—To "MONTY."—*Re* answer to "Isis," I am about making an oil-engine, and, according to my calculations, make capacity of motor cylinder to combustion-chamber at 2¾ to 1, equal 2¾ atmospheres, which at 14·7lb. equals 40½lb. pressure; not 65lb., as stated. Am I in error? 965.

[96562.]—**Lantern Screen.**—Best white, thick and strong linen—thickness gives opacity, strength prevents splitting. Corners strengthened with extra band of strong linen. Some made with eyelet holes at top and sides, other rings along the top and tape along the three other sides for opaque screens. Cover with paper, when dirty, repaper. A costly, but elastic filling is a prepared collodion:—Absolute ether 15oz., absolute alcohol 4oz., pyroxylin 1oz., paraffin wax 7gr. Hard paraffin wax first dissolved in ether, then add alcohol, lastly pyroxylin (soluble gun-cotton). Canvas stretched in frame and dried in hot-air chamber. Collodion rapidly applied to surface to be primed, several coats usually. Oil primings afterwards added in usual way. Collodion may be used itself as a priming thickened with dry pigment, such as Chinese white. REGENT'S PARK.

[96568.]—**Palms.**—Whilst thanking Messrs. Webster Michelson and Co. for their reply, let me assure them that the drawing-room is fully lighted by electricity. Therefore, the answer must be "J. D.'s" "air too dry," for which I thank him. As it is impossible to have the slightest damp in the drawing-room, it is obvious I must have them in the greenhouse. Surely there is a solution to what seems apparently a simple problem? L. R. C.

[96579.]—**Chemical Stylo. Paper.**—Bain, about 1851, used paper impregnated with cyanide of potassium, which gives a Prussian blue colour. REGENT'S PARK.

[96587.]—**Speed Indicator.**—To "W. J. G. F."—Many thanks for yours and "Regent's Park's" kind attention to my query; but in each case there is an important point omitted. In that of the speed indicator, you only state how it was driven—not the principle of the instrument itself, which I presume was that of a high-speed governor, but I wish to be sure. And your illustration of that of the plainimeter is exceedingly clear in all points save one—how is the wheel "attached" to the joint *j*?—what causes it to revolve so as show a definite relation (not ratio, presumably) to the area? SCORPIO.

[96596.]—**Waterproofing and Fireproofing.**—One out of many for fireproofing:—Sulphate ammonia 8lb., carbonate ammonia 2·5lb., boracic acid 3lb., borax (pure) 1·72lb., starch 2lb., water 100lb. Make hot solution of above and steep goods until thoroughly impregnated; afterwards drain, dry sufficiently to be ironed or pressed like ordinary starched goods. Waterproofing.—Linen calico: Use alumina acetate and soak. Used by Belgium coat department. Linen: Solution of alumina sulphate in 10 times its weight of water and soap bath. Or light-coloured resin 1oz., crystallised soda 1oz., water 10oz.; dissolve by boiling. Precipitate rosin soap with table-salt (½oz.), subsequently dissolved with 1oz. white curd soap in 30oz. hot water. Soak goods, or, with made-ups, brush solution and rinse off. Wools: White soap 4½oz., boil in hot water 2½gal.; separately dissolve 5½oz. alum in water 2½gal. Heat two solutions to 190° Fahr. Pass fabric through soap bath and then through alum, and finally dry in open air. REGENT'S PARK.

[96604.]—**Telescope.**—If J. Smith, p. 98, will refer to p. 561 he will find a similar query, strange to say, from J. Smith too—probably another person; but I have an idea that J. Smith is one of those questioners who do not take the trouble to see whether their questions are answered. Out of curiosity I have looked up the matter, and find that the first Mr. Smith was fully answered on p. 576. As to lenses for making telescopes, I think there is a little book published which gives instructions, but the telescope won't show mountains 70 miles off to a person standing on the sea level. T. O. JONES.

[96604.]—**Transformer.**—No; because, your dynamo being a continuous current machine, could not work a transformer. You might charge ten accumulator cells arranged five in parallel, and then the two parallel sets arranged in series, and this would enable you to light a number of 20v. lamps, according to the capacity of your accumulators. I may point out that you will have considerable difficulty in procuring 20-volt lamps that shall give 16-candle power. S. BOTTONE.

[96605.]—**Gas Pressure.**—This problem depends on "Boyle and Mariotte's Law," which states that the volume of any gas varies inversely as the pressure—i.e.—

$$(1)\quad V^1 P^1 = V_2 P_2$$

where V^1 and P^1 are the volume and pressure in one case, and V_2 and P_2 the volume and pressure of the same gas at any other time at the same temperature. In the case given the equation to use will be—

$$(2)\quad V_1 P_1 + V_2 P_2 = v p.$$

Let V_1 = volume of small cylinder = 5c.ft.
P_1 = pressure in small cylinder = 100lb. per square inch
V_2 = volume of air (if any) in large cylinder = 20 − 5 = 15c.ft.
P_2 = pressure of air in large cylinder = atmospheric pressure = 15lb. per square inch.
v = final volume of mixed gases = 20c.ft.
p is required

(I am taking it for granted that the larger cylinder will contain air. If it is a vacuum, use equation (1).) Applying equation (2)—

$$(5 \times 100) + (15 \times 15) = 20 \times x$$
$$500 + 225 = 20 \times x$$
$$x = \tfrac{725}{20} = 36\tfrac{1}{4}\text{lb. per square inch.}$$

I think the above should make the problem clear. J. BENNETT.

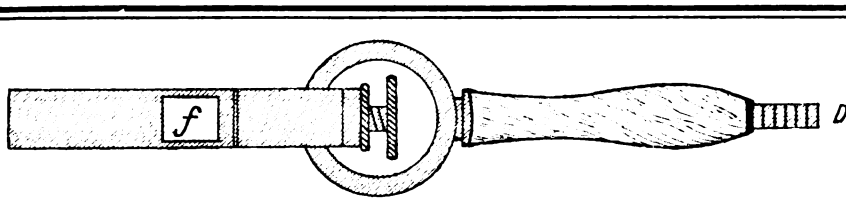


FIG. 1.

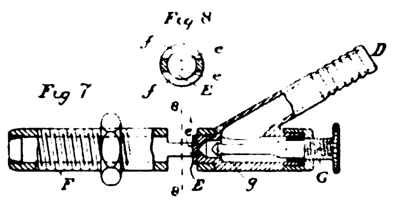
[96603.]—**Gas Blowpipe.**—A tool as illustration, Fig. 1. For details of construction, see Figs. 7 and 8. With a gas supply to it passed through a high-pressure foot-blower (such as are used for supplying "air" to gas blowpipes) would give the greatest heat possible from coal-gas. The blower would raise the gas to a pressure of about



300/10ths, so the orifices (*e*) from which it issues would need to be only minute ones. The air necessary to produce perfect combustion would be drawn in through the apertures (*f*) by the powerful inductive action of the gas.

GAS UNDER PRESSURE.

[96606.]—**Defective Battery.**—From your query I think you mean that you have connected a wire to zinc and another to porous, and a third wire to both zinc and porous at the same time. If that is so, then you will certainly feel no current, for it all takes the easiest path through the third wire direct. Connect one wire to zinc and another to terminal on porous, and put the ends on your tongue. You will feel it then if battery is charged properly. As far as I can make out, I take it to be a Leclanché battery. A. DRYSDALE.

[96607.]—**Mummy Wheat.**—It is an undoubted fact that some grains of corn—oats, I believe—that were taken from a mummy case germinated and ripened in England; but it was afterwards proved that the cases had been stored away for months in the Khedive's stables, and that the grain probably got in there. I have just spent a few months in Egypt superintending some work, and actually saw a case opened, and paid half a sovereign for a few ounces of wheat. As the grains seemed somewhat shrivelled, I soaked them in a glass of water, which afterwards appeared to have a faint blue colour. A few drops of ammonia solved the mystery, and proved that the ancients understood the virtues of sulphate of copper—or!! CLYTIE.

[96608.]—**Electric Clock.**—I think a good Daniell battery would be better than a Leclanché. It is, anyway, more constant, and does not require much attention when constantly employed. Zinc and copper sulphate are the only materials used up, and the products have a certain value. The Daniell can stand more hard work, I believe, than any other. Each cell gives about $1\frac{1}{12}$ volt approximately, so you need 6 cells = $6\frac{1}{2}$ volts. A. DRYSDALE.

[96608.]—**Electric Clock.**—I do not think you can beat Leclanché cells for this class of work. S. ELLIMAN.

[96611.]—**Voltmeter.**—To MR. BOTTONE.—About 10yds. No. 38 German silver wire, silk covered. But before starting work, you would do well to read the chapters on the construction of voltmeters in my "Electrical Instruments." S. BOTTONE.

[96614.]—**Charging Pocket Accumulator.**—The Siemens H dynamo is not adapted to charging accumulators. S. BOTTONE.

[96615.]—**Brown Boot-Polish.**—Phosphin is no doubt short for phosphine, a dye-stuff—an aniline yellow or orange, discovered by Nicholson, and made by Brooke, Simpson, and Spiller. Have you tried the well-known firm in the North—viz., Taylor, of Leeds, or at their branches? REGENT'S PARK.

[96615.]—**Brown Boot-Polish.**—I tried several of the beeswax and turpentine mixtures for my brown boots, but must say that, in my opinion, none of them proved satisfactory, owing to their causing the leather to harden and crack. If "Stella" will try the following recipe, which I obtained from the "E. M." a year or two ago, he will, I am sure, be pleased with the result, as I found it to keep the leather beautifully soft and supple. Mix together:—One pint of sour milk, 1oz. hydrochloric acid, ½oz. powdered alum, ½oz. powdered gum-arabic, scent with a few drops of oil of cloves. Phosphin, as mentioned by "Regent's Park," is, I believe, an aniline dye used by manufacturers for staining the leather a yellow tint. A. H. D. M.

[96615.]—**Brown Boot-Polish.**—I have the following recipe for a brown boot-polish, and perhaps it will be useful to your correspondents, though I have not tried it:—10oz. of good malt vinegar, 10oz. (fluid) of filtered water, 2oz. of good glue, 1dr. of soft soap, and 1dr. of isinglass. Colour with anatto or turmeric, or any of the aniline browns to the shade required. First mix the water with the vinegar, then dissolve the glue in the fluid by gently heating it; add the colouring matter and other ingredients, and boil from ten to fifteen minutes until all the ingredients are thoroughly dissolved and mixed together, then strain the mixture and put in a jar for use. To use this composition, lay it on with a clean sponge, and polish with a soft rag. If the mixture is too thick it may be thinned down with equal parts of vinegar and water; but, of course, it must be reboiled so as to get the vinegar and water to thoroughly intermix. In reply to a further question, I beg to say that "phosphin" is a mineral, and is used along with aniline brown stains to get the various shades in leather-staining. I might just say that it is very expensive, and very good stains can be got by using aniline stains alone, which can be got, I think, from some of the chemists in Manchester; if not, look through a Directory for manufacturers, and write to some of them, and you will then, no doubt, get what you require. If you require any particular shade, you had better send a sample of the colour you require, when you will be able to get it matched. W. H. B.

[96616.]—**Motor—Wire Table—Three-phase.**—To MR. BOTTONE.—(1) Wind the armature with about 2oz. No. 24 silk-covered wire. (2) You will find a table of copper wires, giving lengths, resistances, diameters, &c., in any electric-wire dealer's lists. I have given these so often in these pages, that it is not worth while taking up the space in repeating them. (3) A three-phase current is a rotary current produced by the combination of three alternating currents at different phases; the combined displacement between each set of phases being 120°. S. BOTTONE.

[96618.]—**Reducing Temperature.**—If you cannot have a small electric fan constantly moving, perhaps a limited quantity of freezing mixture, such as ammonium nitrate 1, water 1, sodium sulphate 3, dilute nitric acid 2. I could give you twenty-seven more, but think two may do. REGENT'S PARK.

[96619.]—**Electric Organ.**—The two organs could be played together in the way you suggest from one keyboard by electricity; but surely you are not thinking of wasting time and money on what would be a failure so far as the musical portion is concerned. In the first place, the reeds in the American organ and the pipes in the pipe organ would not keep in tune: when played together they are affected in different ways by the temperature—i.e., when the reeds are sharp the pipes sound flat, and vice versâ. A great many experiments have been made to try and get American organ or harmonium reeds to act in conjunction with pipes, but up to the present I do not believe any satisfactory result has been arrived at. If it could be done the use of 16ft. reeds on the pipe organ would be a great advantage, as the Bourdon pipes are frequently excluded from chamber organs, as they occupy so much room. With regard to adding pipes to the American organ, it would not do, for the above stated reasons, and also because the bellows of the American organ are exhaust bellows—i.e., they suck the wind down through the reeds, whereas in a pipe organ the wind is forced up through the pipes. With regard to articles on electric-organ construction, read Robertson's excellent articles which appeared in the "E. M.," and which are now published in book form. Take my advice, and if you have two good organs, let well alone; if you attempted what you propose, you may be certain it would be a dismal failure. If you wish to enlarge your pipe organ this could be done, and I shall be pleased to advise you in the matter. DIAPASON.

[96620.]—**Acids: Etching.**—Steel: Procure rubber stamp with required design made so that the letters and figure to be bitten by acid shall be depressed in stamp. Have plain border around design large enough to allow a little border of common putty to be laid around the edge of stamped design to receive acid. For ink, use resin, lard oil, turpentine, and lampblack. To ¼lb. of resin put one teaspoonful lard-oil, melt, stir in tablespoonful of lampblack, thoroughly mix, and add enough turpentine to make it of consistency of printers' ink when cold. Use this on the stamp in the same manner as when stamping with ink. When metal or plate is stamped, place a little border of common putty around and on the edge of the stamped ground. Then pour within the border enough acid mixture to cover the figure, and let it stand a few moments, according to the depth required, then pour the acid off. Rinse the surface with clean water, take off putty border, and clean off ink with turpentine. Use care not to spill acid over polished part of article. For acid mixture: Nitric acid 1, hydrochloric acid 1, water (by measure) 10. If the effervescence seems too active, add more water. Hot water may be used to rinse off, after pouring off acid. Brass: Paint or stamp sign with asphalt varnish, leaving parts to be etched unpainted; raise a border around outside of beeswax or asphalt, to hold the acid. Nitric acid 1, water 5. Pour acid on ¼in. deep. When cut deep enough pour acid off, clean by heating, wiping, and finally by turpentine. Nitric acid (sp.gr. 140) 16, water 160; potassium chlorate 6, water 100. Mix two solutions, &c. Try one or other of these on nickel, &c. REGENT'S PARK.

[96621.]—**Warts.**—Wash the parts affected in a blacksmith's cooling-trough, and let the water dry in the skin. This will remove the warts in about a week, without pain. AQUALOO.

[96621.]—**Warts.**—I used to be troubled with these. That which did me most good, and eventually removed them, was grinding the tops down with glass paper, followed by the daily application of a saturated solution of salammoniac in water. S. BOTTONE.

[96621.]—**Warts.**—Have cured myself of warts by continually applying common black ink. This should be applied by dipping pen into ink, and then pricking the warts. This treatment should be persisted in for some weeks, or until you will be able to pull it out by the roots. The ink will corrode warts or corns as well as steel pens. IVANHOE.

[96621.]—**Warts.**—Some time ago the *Medical Press* published that these could be easily removed by small doses of Epsom salts. "Several children treated with three-grain doses morning and evening were promptly cured. A case was cited of a woman whose face was disfigured by these excrescences, who was cured in a month by a drachm and a half taken daily. Another medical man reported a case of very large warts which disappeared in a fortnight from the daily administration of 10 grains of the salts." If the salts are thus useful, I should think the removal might be greatly accelerated by making a saturated solution of them, and wetting the warts with the finger. This would aid the internal action of the salts, which are very "lowering" when persistently taken. I have just got rid of four such disfigurements by the outward application of a cancer remedy. I therefore think the salts might act with similar effect. INCOG.

[96626.]—**Brass Coating for Iron Wire.**—If you dissolve good sheet brass in nitric acid until the acid is neutralised, and use this solution to make up a brassing bath, by the addition of strong liquor ammoniæ until the solution acquires a clear deep blue colour, and then add cyanide of potassium until the solution assumes the colour of old ale, you can easily get a good coating on iron wire either by the dynamo or batteries, using about 9 volts pressure. Brass anodes must be used in the bath. For full details as to strength of solutions and precautions to be observed, see Bonney's "Electroplater's Handbook," p. 187, *et seq.* S. BOTTONE.

[96627.]—**Foreign Currency.**—To "ALGOODS."—The Rio de Janeiro Exchange quotation is the value per milreis (1,000 reis), at which the Rio banks would, on that day, receive the greatly-depreciated Brazilian paper currency in payment of their sterling drafts, payable 90 days after presentation, on banks in London. Thus, if 90 days' sight exchange were quoted at 8d., you would have to give 30 milreis of Brazilian paper money for every sovereign payable in London. In Argentina the system is different, the quotation given being the *premium* on gold. Thus, for 100 pesos in gold you would have to pay in "national" paper money 100 plus the quoted premium. Of course, if you have gold to sell, or drafts payable in gold to receive, you are paid for it in paper money according to the quotation of the day. Sovereigns and Bank of England notes are freely accepted in both Brazil and Argentina at full value in currency. Note that civilised life in both countries costs quite double what it does in England. SOUTH AMERICAN.

IT is stated that a coalfield, comprising an area of about 45,000 acres, is being exploited in Cape Colony. It is calculated that one seam will yield 180,000,000 tons of coal of saleable quality.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last, "Marlborough" has replied to 96373.

QUERIES.

[96628.]—**German Yeast.**—Can any reader of the ENGLISH MECHANIC inform me how to make German yeast?—CONSTANT READER, Wellington, N.Z.

[96629.]—**Linoleum Polish.**—I should be glad if any of your numerous readers can give me a recipe for making a linoleum polish or reviver. The best is of a creamy consistency.—CONSTANT READER, Wellington, N.Z.

[96630.]—**Fifty-volt Overtype.**—Will someone in this line help me in making an overtype dynamo, drum armature, 300 candle-power, 50 volts, and about 20 ampères, shunt wound, the size of F.M., gauge and weight of wire, the size of armature, gauge and weight of wire, and how many revs. per minute? Would it do for a small arc lamp as well as incandescent lamps?—the latter I want it for. Will someone kindly respond?—NEW ZEALAND.

[96631.]—**The Eight Queens Problem.**—What is this "problem," and is it possible to solve it? I find it stated as:—"The Eight Queens Problem is the problem of finding the different ways in which eight queens might be arranged on a chess-board so that no two should be in check of each other; in other words, the number of ways of arranging eight pieces so that no two shall be in the same row, column, or line parallel to the diagonal." The problem as stated is vague, because eight "queens," according to their powers in chess, would cover the whole board, but it appears that it is only "eight pieces" that is meant. Can any reader explain? It appears that it has engaged the attention of the most distinguished mathematicians, so there must be something in it.—Q. R.

[96632.]—**Motor Batteries.**—I thank Mr. Bottone for his information about the damping of sawdust. I find that chloride of zinc is difficult to get in large quantities. Will hydrochloric acid killed with zinc do as well? Will Mr. Bottone or any kind reader tell me how to make the battery from beginning to end, or in what back number I can find the information? What is the chemical in the inner cell composed of? Is the canvas in which the carbon and chemical are wrapped prepared in any special way? Must the zinc case be amalgamated with mercury? Why are there vent-holes left in the pitch?—SAWREY.

[96633.]—**Green Water.**—I have built a swimming-bath with bricks, and lined with Portland cement. The water is supplied from a well in chalk, and is pumped up with a windmill. The bath is covered over with glass. When first filled, the water is beautifully clear; but after a week it begins to get green and turbid, and eventually becomes quite thick with a vegetable growth. Can anyone tell me how to cure or prevent this?—QUEX.

[96634.]—**Injector.**—Can any of your numerous readers tell me why a small injector won't work when the water is hot in the tank? If the water is cold, the injector works all right.—R. GEDDES, Castle Douglas.

[96635.]—**Solder.**—Can any of my fellow readers inform me of a mixture that is more fusible than ordinary tinman's solder, but still stand the same breaking strain?—FUSABLE.

[96636.]—**Accumulator.**—Would any reader kindly give me a full and simple method of making up a small accumulator to give about 2½ ampère-hours? Also the method of punching plates, paste for both + and − plates, and how to prepare glass cells?—MOUSETRAP.

[96637.]—**Catarrh.**—Could any reader who has had experience with this complaint state a safe mode of treatment for curing or relieving catarrh of the stomach?—SUFFERER.

[96638.]—**Electric Lamplighter.**—Will Mr. Bottone or other reader kindly say if it is possible to make an instrument with platinum wire to light a spirit-lamp for burning about thirty minutes, when lighted, which would be required about once in the week? Please give particulars as to size of wire, &c.; also how many feet of No. 22 iron wire have the resistance of 1 ohm?—PERPLEXED.

[96639.]—**Motors and Castings.**—Will some reader kindly give me information on the following points? (1) How much work and skill and apparatus are required for making up ordinary advertised castings, &c., of small oil-motors, whether for launch or cycle, from drawings? (2) Is it difficult to attach motor to small phaeton or old tricycle? (3) What is the cheapest and most economical primary battery for small lighting installations?—R. S. EDWARDS.

[96640.]—**Silver-plating.**—Will Mr. Bottone please give me a recipe for making up a vat to silver-plate a frame that has been already copper-plated? I should prefer to use a vat separate from a battery, and not combined. Can he also say how I can renovate a sandbag that looks old and discoloured through wear.—REWOBOLE.

[96641.]—**Water Taps and Oil-Engine Valves.**—Will one of "ours" kindly tell how to regrind-in water taps that have worn badly, also valves for oil-engine, as I have had no experience in this work?—METAL TURNER.

[96642.]—**Irritation.**—I am suffering from a great irritation of the skin just round the anus, which at times is accompanied with a discharge of a clear colour, similar to that from a blister when snipped, and it causes great itching. The appearance is as though the part had been scalded. I have suffered more or less at that part for the last two years occasionally, but it now is much more frequent. Can any of our medical readers suggest a treatment? I have tried many ointments, some of which give temporary ease only. I am 69 years of age, and in otherwise perfect health.—J. HOPE.

[96643.]—**Relief Stamping.**—Would some reader kindly describe process of relief-stamping note-paper in colour, and kind of ink used? Have press and die.—ERIN.

[96644.]—**Marine Engineers.**—Kindly state if a stammer in my speech would prevent me from passing the Board of Trade examinations for a marine engineer? Do any of the Lines exclude one with a stammer from their service? What would be the best course to take if one was 20 years of age before starting to serve apprenticeship in the shops? Is it compulsory to serve five years in the shops first?—W. H.

[96645.]—**Arc Lamp.**—To MR. BOTTONE.—I want to make a hand-feed arc lamp for an enlarging camera I have. Will you kindly tell me how to go about it? The power at my disposal is an alternating current of 100 volts, and my carbons are ⅝in. bare diam. Should I have to put a choking-coil in? If so, what diam. and length should the wire be on coil?—CAMERA.

[96646.]—**Hernia.**—We are promised a reduction in the number of cases of rupture. Will someone competent to describe shortly the means employed kindly do so? There is, or used to be, a "hernia institute" that guaranteed cure of every case undertaken by means of hypodermic injection, and which permitted the patient to continue at his business during treatment. Has this system anything to do with the promise held out?—ERIC.

[96647.]—**Knife-Handle Cement.**—Will someone (not "Regent's Park") give a formula for cement for fixing hollow metal handles to blades of table-knives? The rosin compound softens in boiling water, and hard soldering with silver is, I am afraid, likely to draw the temper of the blades.—M. COLE, West Didsbury.

[96648.]—**Mercury Gauge.**—I have heard that there is a mercury gauge made on the siphon or some other principle to register steam-pressure up to, say, 150lb. per square inch. The gauge is about, say, 18in. long, and the divisions are equal. How is the above made? A sketch will oblige.—DUTCH PAUL.

[96649.]—**Battery for One Light.**—I shall be very grateful to anyone who would kindly tell me what kind of a battery is required for a small incandescent light. Whether wet or dry, what kind of plates, number of wire and exciting fluid, &c.?—IGNORAMUS.

[96650.]—**Trick Matches.**—Please tell me how to make the composition that is put on matches to make an explosion when the flame gets to it (trick matches)? I want them to sell at the fairs. People sell them here, but I cannot find out how to make them. Give the recipe in small proportions, and greatly oblige.—WILLIAM BRITTON, Boston, Mass.

[96651.]—**Transposition.**—Will any kind reader explain to me in a concise manner how to be sure of transposing a division sum—say one as follows: $\frac{A \times B \div C}{d + e}$? What I want is to transpose the sum so as to find out the values of A B C d e. If too long, kindly mention a book in which the matter is properly explained. The signs in the sum may be different.—N. I. X.

[96652.]—**Calcite.**—The mineral calcite, or Iceland spar, is merely calcium carbonate crystallised in the hexagonal form, and is found on Eskefjord, in Iceland. Is the mineral found at other places crystallised in the same form, or is the above mine the only one producing "Iceland spar"?—FLEUR-DE-LYS.

[96653.]—**Sailing Boat.**—Could any reader of "ours" oblige with the lines and dimensions of the skimming, dish-type of sailing boat so much in favour on the Upper Thames? They seem to be built carvel in all cases, and of mahogany, length about 25ft. There is also a slightly different type, with vertical sides instead of rounded. In either case the bow and stern rise clear of the water. The latter type is flat-bottomed, with a rising floor fore and aft. The mast is stepped right for'ard, but they sometimes carry a small jib on a short bowsprit. Both types have centre-boards, and carry very large rudders. I thought of building one of the latter type during the winter, if I could get the lines and dimensions.—W. J. SHAW.

[96654.]—**Turret Clocks.**—Will someone kindly inform me as to the best illustrated work upon turret clocks?—W. A. P.

[96655.]—**Silvering Polished Glass.**—Will any fellow-reader experienced in this work kindly give me a reliable recipe for precipitating a perfectly opaque coating of silver on any polished glass surface, so that the coating shall stand gentle polishing after precipitation? As little silver nitrate as possible to be employed in the process. An average working temperature of 60° Fahr. to be understood.—R. H.

[96656.]—**Bookbinding.**—Is bookbinding within the capability of an ordinary amateur as a hobby? I should like to know what tools are required, and how are the edges cut? I understand the way to sew the sheets, and the manner in which the tapes are inserted and fastened to the boards. I should like to be able to turn out really good work. The names of any books on the subject would be acceptable, and any hints welcomed by—AMATEUR BOOKBINDER.

[96657.]—**Laundries.**—What are the materials which are commonly used in laundries to assist in the bleaching and washing of the cotton and linen? Some laundries appear to use chemicals which eat holes in the fabric and cause rapid degeneration, whereas similar articles treated in the old-fashioned way in the family washtub do not give way in a similar manner.—T. J.

[96658.]—**Rheumatism.**—Some few months back I suffered with rheumatism in the knees, which yielded to a few doses of Salol and persistent friction with turpentine liniment. A week or two later, however, similar pains were felt in my hands, which are persistent in spite of liniment and friction, and in addition when the fingers are flexed two of them become fixed as with cramp, and when forcibly extended, again go back with a jerk and snap. I am 60 years of age, and have never known any serious illness save a serious attack of "grippe" some seven years since.—FINEM RESPICE.

[96659.]—**Joy's Valve-gear.**—I am building a launch with triple-expansion engines, 5in., 8in., and 13in., 8in. stroke, to run 350 revs. per minute, space being a consideration. I wish the valves on the side, and have stipulated for Joy's valve-gear. I am now told that whilst this runs very satisfactorily for a time, there are so many pins which, at a speed anything like above, soon wear loose and rattle. These pins I understand are not made adjustable, which, I fancy, would overcome to a great extent my objection; but, of course, one has to take these things as the patentee makes, or leave them alone. Have any of your readers experience of this valve gear in marine-work, or can they recommend any other form or make of valve-gear working on the sides of the engines?—F. C. B.

[96660.]—**Ringing Anvil.**—Will any reader kindly advise the best method of preventing the ringing noise of an anvil?—H. H. S.

[96661.]—**Regulating Capsules for Incubators.**—Will one of your readers oblige with information how to make above? I have tried thin hard sheet-brass without success. I am also uncertain what spirit is used. Have tried naphtha, ether, &c., but cannot get satisfactory results. I know the mechanical movements, but fail in the expanding capsule.—POULTRY BREEDER.

[96662.]—**Thunderstorm.**—Would any of "ours" kindly enlighten me on the subject of thunderstorms? I saw some time back in the "E. M." (I cannot say the number now, as I have not been able to find it), that if a person were wet through there would be no danger of being struck by lightning. I have seen repeatedly animals brought in killed by lightning; they have been out in the fields thoroughly soaked in rain. I remember two young horses being struck; they were both standing back to the storm in the open fields, and were struck from behind, bursting their entrails and forcing the contents between the flesh and hide down to the hock or knee. Have also seen cows and bullocks brought in after a storm that were picked up out of the fields with not a mark or burn of any description to show where or how they were struck; have seen the men unhide and cut these animals up, but there was nothing unusual to be seen, the only thing the bodies decompose very quickly. There was a man killed here yesterday (Sept. 6) sheltering under a large elm tree, the tree having large pieces of bark stripped off. This is the question: The animals were killed soaking wet, the man comparatively dry.—F. H. B., Stanstead Abbotts.

[96663.]—**Wimshurst.**—Will Mr. Bottone or others advise me on the following defects of 4-plate 20in. machine, 20 sectors on each plate, four salad-oil bottles as supports for prime conductors, bottles filled ⅓in. up with shot, and outside 2in. tinfoil? Prime conductors are 2in. brass tube plugged with wood, and upright conductors ⅝in. brass rod inclosed in brass tube. When working I only get about 3in. spark at discharging balls, and a powerful spark occurs at each end of the machine between the outside of jars and the neutralising rods, which are fixed in movable boards inside the case of machine, as in Grey's book. I think, also, the current escapes right through the glass tubes which cover the upright conductors. If I approach a brass rod, or my finger to the glass tubes, I get a discharge through the glass. The main balls on top of upright rods are solid, and 1in. diam., and the discharging balls are ¾in. and 2½in. respectively. The neutralising rods are connected by insulated copper wire. Do the bottom or outside of jars require to be insulated from the frame? Do the neutralising rods require insulating?—H. H.

[96664.]—**Sunken Ships.**—Will some reader tell me whether there are any important sunken vessels lying at a depth greater than 200ft., or, in other words, vessels which cannot be reached by ordinary diving apparatus?—INQUIRER.

[96665.]—**Coal and Electricity.**—At the present time I am driving my works by steam-power, and require 250I.H.P., and the requisite coal has to be carted four miles to the works, rising in transit nearly 700ft; consequently only small loads can be brought, which makes the cartage expensive. I have land at the station where the coals arrive, on which I could erect engine and boiler, &c., and think it might perhaps be economical to convert the coal into electricity there, and bring a cable to the works and drive by motors. I shall be greatly obliged if any of your electrical readers can advise if the scheme is feasible, and the probable cost of cable, dynamo, and seven motors? The cartage costs 3s. 4d. per ton.—H. JAY.

[96666.]—**To J. Dormer.**—Thanks for answer to Ferro. (96406, p. 583). Would you mind telling me what makes solution soak through the paper? I have only floated pieces about 6in. by 6in., but it soaks right through. Do you think a little more gelatine will do any good? Otherwise solution is very satisfactory.—W. J. A.

[96667.]—**Wheel-Cutting.**—Will some reader please give me instructions in the following? I want several small brass toothed wheels, after the style of clock-

wheels, but about ¼in. thick, and I want to cut them myself, if possible. This is my fix: If I go to a shop for cutters, I get one only of a certain pitch, whereas I have always understood that the tooth-shape of a driven wheel is different to that of a driver. How are they cut in actual practice? I have lathe, overhead, division-plate, &c.—AMATEUR.

[96668.]—**Mirror-Back Showcards.**—Can any one of "ours" tell me how the bronze powder is put on the glass to get this effect.—SIGN WRITER.

[96669.]—**Mercury's Mass.**—Could anyone oblige with the mass of Mercury? What is the figure generally assumed? Has anything in this direction been done recently?—GARSDALE.

[96670.]—**Spring Motors.**—Would any reader kindly give a description and sketch of a simple, strong, and cheap elastic or spring motor, suitable for driving experimental models, such as those used in children's automatic toys? I want to drive a small shaft for a short time at a high rate of speed.—PI.

‖[96671.]—**Solvent for Gum.**—Will any reader kindly let me know the best and cheapest solvents for "gum euphorbium."—AN OCCASIONAL READER.

[96672.]—**Mexican Furnace Chimney.**—I would like very much to know where I could get information about a furnace stack built in Monterey, Mexico, by Mr. William Drysdale, of Bonnybridge, Stirlingshire. A paragraph appeared about it in the *Falkirk Herald* for March (I forget which date exactly, but it was near the end), being copied from the *Mexico Monterey Daily Globe* of March 14. The chimney is stated to be the tallest and handsomest in the Mexican Republic. The height stated was 185ft. Where could I get more information about the chimney and its architect, Mr. William Drysdale, who is said to be an expert at this work, or where could I get a copy of the Mexican paper? Perhaps some Mexican reader may see this, and oblige—A. DRYSDALE.

[96673.]—**Aluminium.**—Will any kind reader tell me how to make use of a lot of lump aluminium? If I could, I should like to be able to turn it into very fine powder to use for painting with. I have about 3lb.—ALUM.

[96674.]—**To Mr. Bottone.**—Would Mr. Bottone please tell me how much wire, and what gauge, to put on a model standard type dynamo which I am making (I want it for incandescent lamps), and what would be the best speed for it to run at? The dimensions are: Magnets $2^8/_{16}$in. by 1¼in. by $4^3/_{16}$in. over all; armature, diam. 1¾in., length 2¾in.; Siemens H pattern. I should like to get 15 or 20 volts. What kind of armature would be best for charging accumulators?—L'ALLEGRO.

☛[96675.]—**Railway Lines.**—In laying down the metals for railways, a certain amount of "play" is allowed for expansion under hot sun. What is done in the case of the tram and other rails which are electrically welded, and are practically without a joint?—BUCKLE.

[96676.]—**Bookbinding.**—I have been binding three volumes of ENGLISH MECHANIC, but find great trouble in cutting edges clean; been using large carving-knife. A small sketch or explanation of any unexpensive device would be gladly received by—GLASGOW.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1692.—By H. CUDMORE.

Black. [6 pieces.

White. [7 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Sept.* 25.)

Solution of PROBLEM No. 1690.—By E. PRADIGNAT.

Key-move, P-B 4.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1690.—Correct solution has been received from E. Lobell, jun. ("A very nice mate"), W. Hamm (Wimbledon), E. C. Weatherley, G. W. Underhill (Weybridge), Geo. Christie, Whin Hurst, Richard Inwards, Hampstead Heathen, Quizco, J. E. Gore, Rev. Dr. Quilter ("Admirably constructed"), F. B. (Oldham), A. Tupman, who rhymes as follows:—

" A sentinel he stood throughout the strife,
Now on his move depends a monarch's life.
A pretty trick indeed, for White to force
A pawn past pawn, and win the game of course."

PROBLEM No. 1689.—Further correct solutions received from M. N. Munro, T. Cox.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, Sept. 13, and unacknowledged elsewhere:—

W. J. G. F.—Martin Luther Rouse.—Meteor.—Ureka.—S. Elliman.—Clytie Dudley.—Monty.—H.—Pressure.—A Fellow of the Royal Astronomical Society.—Stud.—O. R. Walkey.—E. Wilson.—Chemical.—T. G. W.—Wm. F. Rigby.—Lanky.—Motor-mad.—A Beginner.—F. P.—Miliner.—Sala.—Member B. C. and A. Assn.—J. Harding.

J. P.—Better advertise in the Sydney papers, we suppose. Sell, G. Street, and Co., or any well-known London advertisement agent will do that for you. Quite outside the scope of our query column.

SMOKER.—We have, of course, tried the *Weekly Times and Echo* cigars, and our opinion is that they are, by comparison with others sold of the same size and quality, worth three times the price charged for them.

B. B.—A useful work is "Hot-Water Heating," by F. A. Fawkes, published by B. T. Batsford, High Holborn; there are several books on the subject. You will find an illustration of the method of fitting baths with hot and cold water in No. 1397, Oct. 23, 1891.

W. MURGATROYD.—The only way to obtain such a position is to apply to the owners of the vessels. The qualifications are the ability to keep accounts, and some knowledge of markets when it is necessary to buy provisions. They are positions not easily obtained.

STATURE.—You can have boots made with extra double-thick soles. You might increase your height a trifle by judicious exercise, but "elevators" are simply something to stand on.

LONGS.—For bamboo working see Vols. LV. and LVI. Full particulars are given therein.

D. EVANS.—Please see the back numbers. The questions have been answered many times.

ELECTRO.—Simply send a specimen, or tell the printers to put certain words in "Clarendon." They will understand. 2. Impossible to say: it varies with the reputation of the author and the demand for his works. Say 20 per cent.

H. H. S.—You can mount the anvil on rubber blocks; but query inserted for opinions of readers.

REU.—Probably the aniline black would answer, or the usual method—logwood first, and then a solution of sulphate of iron.

J. H. PRICE.—If not answered before it reaches the Unanswered list, it might be put in another form. It is, however, doubtful if there is a work that would be helpful. 2. The catalogue can, we presume, be obtained from Sir Howard Grubb's Works, Rathmines, Dublin.

CURVE.—A useful book is Molesworth's "Pocket-Book," published by E. and F. N. Spon, Ltd., 125, Strand, W.C. See Hints to Correspondents, No. 5. A civil engineer is a man who has been a student under a civil engineer, or who is a member of the Institute of Civil Engineers. There are, no doubt, some science classes in your town where you could obtain information and probably see the books. If you send to Messrs. Spon for a catalogue, you will find in their list a number of books which may suit you.

SEA VOYAGE.—The only way is to apply to the owners of the vessels, or to the captain or mate.

W. M. FOLLETT.—There are the articles which have appeared in the back numbers, and "Bicycles and Tricycles," by A. Sharp, B.Sc., published by Longmans, Green, and Co.

HIRSUTE.—Hair thins after illness, or during years of indigestion, or in old age, because of the diminution of nourishment to the roots. Curling-pins and tongs also help to destroy the hair and injure the growth. In some cases ordinary petroleum, rubbed well into the scalp daily, has been known to restore the growth of the hair; but in old age we do not think it will do much good. The professional "hair-restorer" is mostly an empiric, and the best proof of the futility of his pretensions is the baldness of so many royal, rich, and exalted people, who would pay anything for a really efficient hair-restorer, if it were possible to obtain it.

IN TYPE.—W. H. Bell.

IT is rumoured that either Seattle or San Francisco will, within the next few years, be made the terminus of a new Trans-Pacific steamship line to connect with the Trans-Siberian Railroad.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, SEPTEMBER 22, 1899.

MOTOR CYCLES.—XVIII.

IT will not be long before the possessor of a motor tricycle will want to take a friend out with him on his machine. This can be done by attaching a "trailer" or small light carriage behind the machine or by means of a detachable fore-carriage converting the tricycle into a quadricycle. The first arrangement is unsatisfactory, inasmuch as conversation is practically impossible, and any odour from the motor becomes unpleasantly noticable to the passenger. The fore-carriage is distinctly better in every way, though it is more expensive and troublesome to construct. Fig. 107 shows a design which is as simple as any, and will be found both efficient and comfortable. The two side tubes A A′ are of 1¼in. by 18 B.W.G. weldless steel tubes. They are bolted at the rear ends to the same lugs, on the bridge-tube, to which the rear stays from saddle-clip, are fastened. Bolts of the same diameter but slightly longer will be used to hold them and the saddle-stays, to the bridge tube-lugs. These two main tubes are braced together at the front end by a cross tube, B, of the same diameter and gauge, and a bridge, C, holds them firmly to the down tube of the tricycle. This bridge can either be a malleable iron casting, or can be made up of lugs and two short tubes. I shall follow the latter method in the detail drawings.

The steering-gear is on the Ackermann principle, and will need to be carefully made. It will be readily understood that when turning a corner the two front wheels do not run round curves of equal radii. To make it safe to turn at anything over a mile or so per hour, it is imperative that the steering wheels should be each deflected to the proper angle so that they may roll around the curves and not scrape sideways. Whatever be the radius of the curve the machine is travelling around, the centre lines of the axles of all four wheels should meet at the centre of that radius. The links and levers, as shown in Fig. 107, while not theoretically correct in this respect, are as close an approximation as is necessary in practice. The dotted position of the front wheels in Fig. 107 corresponds to a curve of 8ft. radius, and the two centre lines D D′, if produced, would meet at a point on the centre line of back axle, also produced, 8ft. from the longitudinal centre line of the machine. I have worked out this steering gear full size, and will give all dimensions in my next when treating of the details of fore-carriage. The front axle, which is tubular, is attached to the machine by light elliptic springs. These should be bought, or can be ordered from any local carriage-smith, the needed particulars being 20in. centres, three plates 1¼in. wide. Distance between top and bottom bows 4in. when loaded with a man's weight. The front seat is to be padded and sprung, and will form the lid of a tool-box. The sides of tool-box and foot-plate and sides will be made of wood. I have made the seat, footboard, and its sides rather larger than usual for machines of this class. This I consider a necessity for comfort. During

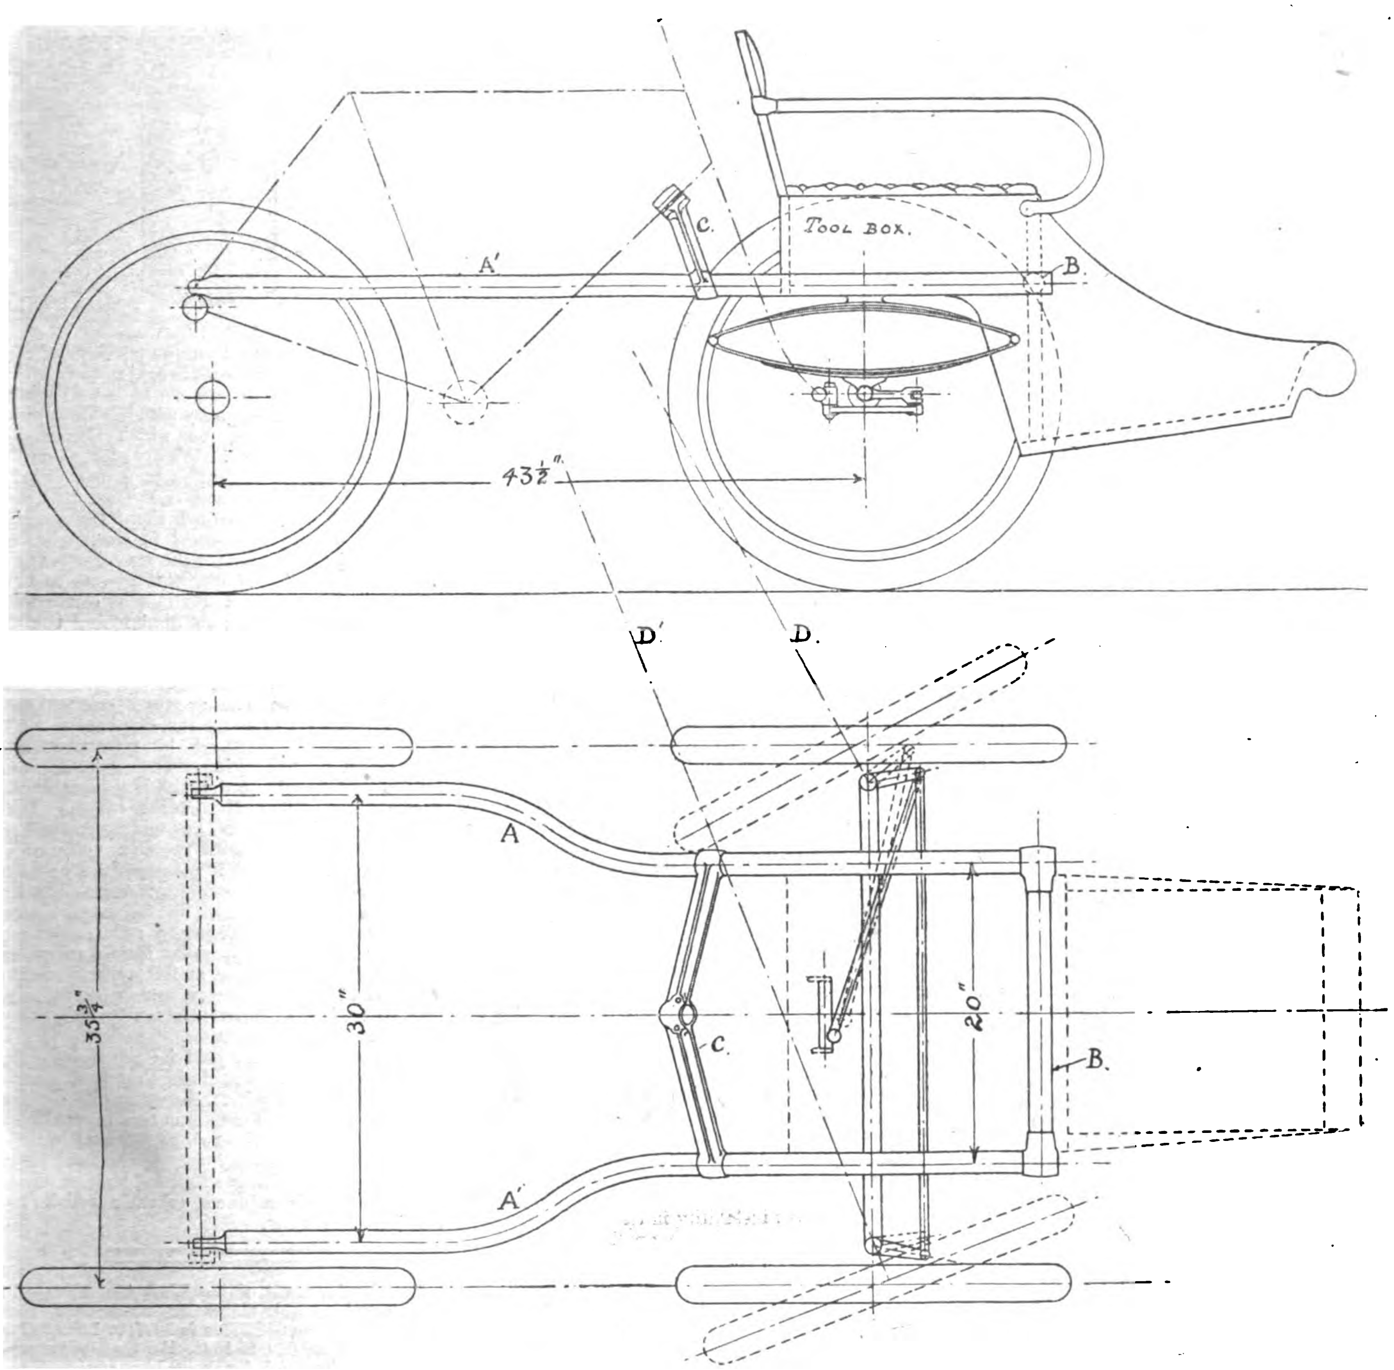

FIG. 107.

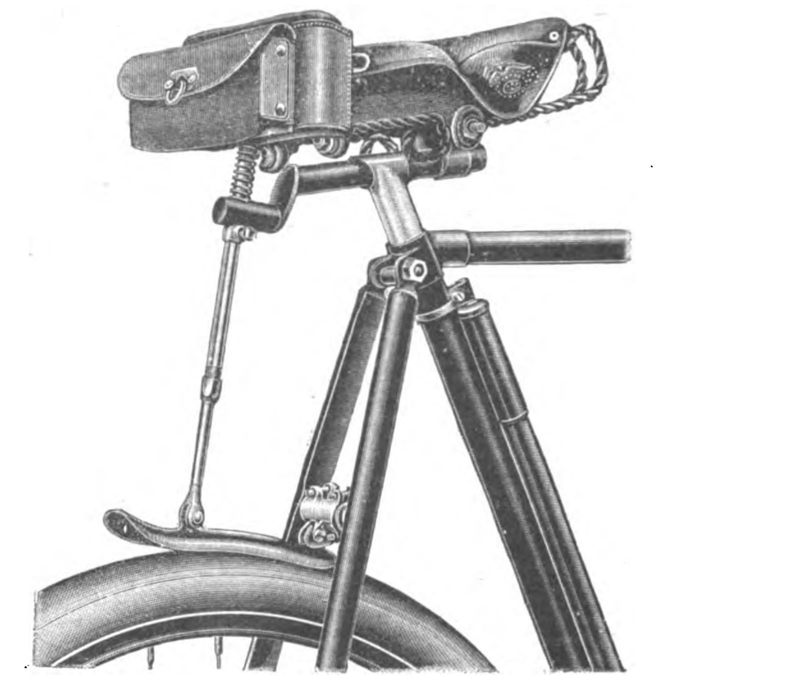


long drives a cramped position becomes very tiring. It will not be a difficult matter to arrange the tricycle front-wheel brake-lever to actuate a spoon brake on each back wheel, thus retaining two independent brakes on the machine when converted to a four-wheeler.

In order to avoid confusion, I have shown the existing tricycle-frame by centre lines only, using full lines for the new work. To insure plenty of power for hill-climbing, it will be advisable to somewhat lower the gear between motor and driving-axle, using for the driving-pinion 11 teeth instead of 13, and 102 teeth for the gear-wheel in place of 100, as originally intended. The gear of the tricycle being 7·69 revolutions of the motor to one of the axle, the new combination gives a ratio of 9·27 to 1, the distance between the centres of wheel and pinion remaining the same. An increase of power will result, though the speed of the machine will be reduced.

An extra supply of petrol can be carried, in a suitably-shaped vessel, slung under the tool-box in the space between the springs and in front of the fore-axle. A couple of good-sized foot-rests for the rear driver can be attached to the bridge C, and will be found more comfortable than keeping the feet on the pedals all the time.

COLE'S SAFETY SADDLE-BRAKE FOR BICYCLES.

THE inventor of this brake, a very old friend of "Ours," claims that it overcomes the chief danger to cyclists, as it is the only brake that renders it impossible to lose control over the machine under any conceivable circumstance. It is entirely distinctive, and is the simplest, the cheapest, the lightest, and the most efficient brake in existence.

The distinctive feature of this brake is the method of actuating the brake by utilising the weight of the rider's body through the medium of a rod or tube connecting a rest, or projection (which also forms the tool-pouch) at the rear of the saddle with a friction-plate or spoon, by which means an absolutely controlling brake is depressed into contact with the hind wheel. It dispenses with the use of a front brake, which is objectionable in any form (unless it be desired to retain the double security of a brake on each wheel). Its weight is less than that of the ordinary handle-bar brake. It is far more powerful than any brake in existence—so much so, that by its application the machine can be stopped, without danger, even on the steepest hill. It is not unsightly, like the usual front brake, nor an element of danger, as the handle has frequently proved, and it leaves the handle-bar unencumbered for other uses, and also facilitates the lamp being carried (as it ought to be) on the fixed socket instead of on the steering head. It utilises the tool-pouch among its component parts, thereby making it serve a double purpose, and reducing weight and encumbrance. Although so powerful, it is scarcely observable, and its appearance is extremely neat and unobtrusive on the machine. It is applied directly, and not by means of cranks, or levers, or cords, and with the whole weight of the body if desired. It does not throw mud or dust on the rider, as the front brake does. It does not injure the tire, as the ordinary plunger brake does, by pressing on a small portion of it. The pressure of this brake is extended over a large surface, and is found in practice not to cause the slightest injury—the wear being on the spoon and not on the tire. It can instantly be applied with the greatest facility, lightly or heavily, as desired by the rider simply moving or rolling his seat slightly backwards on the saddle. In so doing, he does not alter his position by any other motion—not requiring to use either his hands or his feet. He can, however, apply it by putting back one hand. The brake is instantly released on the rider resuming his normal position on the saddle, or removing the pressure of his hand. Being applied to the hind wheel, there is not the same strain to the frame of the machine by the sudden application of the brake as when applied to the front wheel, which throws all the strain on the front fork as the momentum of rider and machine is left unchecked behind it. This is a most important consideration in ladies' drop-frame bicycles. Nor is there, with this brake, any element of instability in its application, as is the case with any brake applied to the front wheel, which is, mechanically, an essentially bad arrangement. Consequently there is no danger of an upset by applying it suddenly, no matter how rapidly the machine may be running. It therefore removes all risk in getting on an unknown or dangerous hill, and so gives perfect confidence to the rider at all times. It affords perfect safety, inasmuch as it will instantly pull up the machine either in case of imminent collision or on any hill—even though the chain should break (as is liable to happen, particularly in strong back-pedalling) or come off when descending a hill, as sometimes occurs, or the tire should puncture (for if so, the spoon comes down on it when deflated), or the rider should lose the pedals—he still retains absolute control over the machine at all times, as he practically sits on the hind wheel, and so can stop under any circumstance without the slightest tendency to overthrow or disturb his equilibrium. Its cost is less than that of any other brake. There are also forms (provided for in the patents) in which it can be applied on either rim or hub; but this on the tire is found preferable, as it has none of the many objections which are inseparable from any form of rim-brake. It can be had of all agents, and of the manufacturer, W. E. Brough, Cycle Works, Basford, Notts.

A NEW EYEPIECE.

THE working microscopist sooner or later has in his battery of objectives lenses of both the achromatic and apochromatic type, and many would add at least one objective of the latter series to his equipment but for the heavy

additional cost involved in the purchase of compensating eyepieces to work in conjunction with it. These compensating eyepieces, as is well known, do not work advantageously with the lower power achromatic objectives, for which Huyghenian eyepieces are necessary. We are glad, therefore, to be able to call attention to a new eyepiece introduced by W. Watson and Sons, 313, High Holborn, W.C., and called the "Holoscopic" eyepiece, which is arranged to work with any form of objective. It is of the Huyghenian type, but the lenses are of different glasses to those hitherto employed, and a range of correction is obtained by increasing or diminishing the distance between the eye and field-lenses. The outer tube which fits into the microscope carries the field-lens at its lower end, and at the upper part receives the sliding tube on which is mounted the eye-lens and the diaphragm. This will be better understood by reference to the illustration accompanying this. A scale is engraved on this tube so that the best position may be registered. When the sliding tube is pushed home the eyepiece is an undercorrected one suitable for working with the achromatic objectives; when extended it possesses the so-called over-correction associated with the compensating eyepieces for working with apochromatic lenses.

Every item that efficiently reduces cost and the duplication of apparatus is important, and this eyepiece, combining, as it does, the working qualities of both eyepieces, and without sacrificing excellence of performance in either case, should receive appreciation. The price is very little in excess of that paid for the Huyghenian eyepieces alone. It is made in a range of powers, full particulars of which, together with detailed description, will be found in a new twenty-four-page supplemental list which Messrs. Watson have just issued for the coming season, and which contains many striking additions, both in microscopes and their adjuncts, to their well-known fully illustrated list.

The developments of the West Australian gold-fields are of a highly satisfactory nature, the export having risen from 674,933oz. in 1897, to 1,050,000oz., valued at £4,000,000, in 1898. For the eight months this year so far 993,123oz. have been exported.

The unsanitary condition of Naples is gradually being remedied. In the old quarters of the city ten miles of new streets have been made during the last ten years. The result of the new drainage arrangements has become very apparent, and deaths from infectious diseases are said to have greatly diminished.

Mechanism has been installed in one of the steeples of St. Patrick's Cathedral, New York City, for ringing the chime of bells. There are nineteen bells, which vary in weight from 300lb. to 7,000lb. The mechanism for striking, says the *Scientific American*, consists of horizontal air cylinders, with piston-rods attached to central studs projecting below the centres of the clappers. The piston is only used for a stroke one way, the weight of the clapper returning it. The bells are operated by a keyboard which is in electrical connection with magnets controlling the valves of the air cylinders.

THE BRITISH ASSOCIATION.

ADDRESS IN MATHEMATICS AND PHYSICS.

THE Address in Section A was delivered by Prof. J. H. Poynting, D.Sc., F.R.S., in the course of which he said:—While the investigation of Nature is ever increasing our knowledge, and while each new discovery is a positive addition never again to be lost, the range of the investigation and the nature of the knowledge gained form the theme of endless discussion. And in this discussion I believe that in some directions there has been real progress, and that physicists are tending towards a general agreement as to the nature of the laws in which they embody their discoveries, of the explanations which they seek to give, and of the hypotheses they make in their search for explanations. I propose to ask you to consider the terms of this agreement and the form in which, as it appears to me, they should be drawn up. The range of the physicist's study consists in the visible motions and other sensible changes of matter. The experiences with which he deals are the impressions on his senses, and his aim is to describe in the shortest possible way how his various senses have been, will be, or would be affected. His method consists in finding out all likenesses, in classing together all similar events, and so giving an account as concise as possible of the motions and changes observed. His success in the search for likenesses and his striving after consiseness of description lead him to imagine such a constitution of things that likenesses exist even where they elude his observation, and he is thus enabled to simplify his classification on the assumption that the constitution thus imagined is a reality. He is enabled to predict on the assumption that the likenesses of the future will be the likenesses of the past. His account of Nature, then, is, as it is often termed, a descriptive account. Were there no similarities in events, our account of them could not rise above a mere directory, with each individual event entered up separately with its address. But the similarities observed enable us to class large numbers of events together, to give general descriptions, and, indeed, to make instead of a directory a readable book of science, with laws as the headings of the chapters, which are, I believe, in all cases brief descriptions of observed similarities. If this is a true account of the nature of physical laws, they have, we must confess, greatly fallen off in dignity. No long time ago they were quite commonly described as the fixed laws of Nature, and were supposed sufficient in themselves to govern the universe. The old conception of laws as self-sufficing governors of Nature was, no doubt, a survival of a much older conception of the scope of physical science, a mode of regarding physical phenomena which had itself passed away. Man, knowing that his purpose and will were followed by motions and changes in the matter about him, thought of similar purpose and will behind all the motions and changes which he observed, however they occurred; and he believed, too, that it was necessary to think thus in giving any consistent account of his observations. Taking this anthropomorphic—or, shall we say, psychical—view, the laws he formulated were not merely descriptions of similarities of behaviour, but they were also expressions of fixed purpose and the resulting constancy of action. They were commands given to matter which it must obey.

ADDRESS IN CHEMISTRY.

The Address in Section B, Chemistry, was delivered by Dr. Horace T. Brown, F.R.S., who said:—The subject which I have chosen for my address is the fixation of carbon by plants—one which is the common meeting-ground of chemistry, physics, and biology. We have become so accustomed to the idea that the higher plants derive the whole of their carbon from atmospheric sources that we are apt to forget how very indirect is the nature of much of the experimental evidence on which this belief is founded. There can, of course, be no doubt that the primary source of the organic carbon of the soil, and of the plants growing on it, is the atmosphere; but of late years there has been such an accumulation of evidence tending to show that the higher plants are capable of being nourished by the direct application of a great variety of ready-formed organic compounds, that we are justified in demanding further proof that the stores of organic substances in the soil must necessarily be oxidised down to the lowest possible point before their carbon is once more in a fit state to be assimilated. It was the hope of gaining more direct evidence on this important question which led me some time ago to attack the problem experimentally, in conjunction with Mr. F. Escombe, the resources of the Jodrell Laboratory at Kew having been kindly put at our disposal by Sir W. Thistleton-Dyer and Dr. D. H. Scott. Up to the present time our experiments have not been carried far enough to enable us to give a positive answer to the main question; but they have already suggested a new method of attack which will enable us in the future to determine, with a fair amount of certainty, whether any particular plant, growing under perfectly natural conditions, derives any appreciable portion of its carbon from any other source than the gaseous carbon dioxide of the atmosphere. In the year 1884 Sachs found that the accumulation of freshly assimilated material in a leaf may, under favourable conditions, go on so rapidly as to give rise to a very appreciable increase of weight in the leaf lamina within the short space of a few hours. By observing at different times of the day the varying dry weight of equal areas of large leaves, Sachs obtained an approximate measure of the rate of the assimilatory process which he could express in terms of actual number of grammes of substance assimilated by a unit area of leaf in unit of time. In this manner he was able to show, for instance, that a sunflower leaf, while still attached to the plant, increases in weight when exposed to bright sunshine at the hourly rate of about one gramme per square mètre of leaf area. In the case of similar leaves detached from the plant, and of course under conditions in which the products of assimilation were entirely accumulated in the leaf, he found an increase in weight of rather more than 1½ gramme per square mètre per hour. It is evident that a far better plan of measuring the rate of assimilation under varying conditions would be the estimation of the actual amount of carbon dioxide entering a given area of the leaf in a certain time, and it was to the perfection of a method of this kind that Mr. Escombe and I first turned our attention.

All such experiments, of course, necessitate not only a determination of the carbon dioxide in the air which has passed over the leaf or plant, but also a simultaneous determination of the carbon dioxide in the ordinary air used. In our experiments the air was in all cases taken from a height of 4ft. 6in. from the ground, the amounts aspirated varying from 100 to 500 litres. The actual intake of carbon dioxide is determined by inclosing the entire leaf in specially-constructed, airtight, glazed cases, through which a sufficiently rapid air stream is passed. These cases are so arranged that the leaf can be inclosed while still attached to a plant which is growing out in the open under perfectly natural conditions, and some of them are sufficiently large to take the entire leaf of a sunflower. The carbon dioxide content of the air is determined both before and after its passage through the apparatus, and since the amount of air passed is known, we have all the data requisite for determining the actual amount retained by the leaf. An experiment generally lasts from five to six hours, and the carbon dioxide fixed in this time may amount to 150c.c. or more, the actual error of determination being very small indeed. In order to show the kind of results obtained in this manner I will give one or two examples. A leaf of the sunflower, having an area of 617·5sq.cm., was inclosed in its case whilst still attached to the plant, and was exposed to the strong diffuse light of a clouded sky for 5½ hours, air being passed over it at the rate of nearly 150 litres per hour. The content of the air in carbon dioxide as it entered the apparatus was 2·80 parts per 10,000, and this was reduced to 1·74 parts per 10,000 during its passage over the leaf. This corresponds to a total absorption of 139·95c.c. of carbon dioxide, or to an intake of 412c.c. per square metre per hour. If we assume that the average composition of the carbohydrates formed is that of a $C_6H_{12}O_6$ sugar, the above amount of carbon dioxide corresponds to the formation of 0·55 gram of carbohydrate per square mètre per hour. The penetration of the highly-diluted carbon dioxide of the atmosphere into the interior air spaces of the leaf on its way to the active centres of assimilation must, in the first instance, be a purely physical process, and no explanation of this can be accepted which does not conform to the physical properties of the gases involved. Since there is no mechanism in the leaf capable of producing an ebb and flow of gases within the air spaces of the mesophyll in any way comparable with the movements of the tidal air in the lungs of animals; and since also the arrangement of the stomatic openings is such as to effect a rapid equalisation of pressure within and without the leaf, we must search for the cause of the gaseous exchange, not in any mass movement, but in some form of diffusion. This may take place in the form of open diffusion through the minute stomatic apertures, which are in communication both with the outer air and the intercellular spaces, or the gaseous exchange may take place through the cuticle and epidermis by a process of gaseous osmosis, similar to that which Graham investigated in connection with certain colloid septa. For many years there has been much controversy as to which form of gaseous diffusion is the more active in producing the natural interchanges of gases in the leaf. In 1895 Mr. F. F. Blackman brought forward two remarkable papers which opened up an entirely new aspect of the subject. After showing the fallacy underlying certain experiments of Boussingault, which had been generally supposed to prove the osmotic theory of exchange, Mr. Blackman gave the results of his own experiments with a new and beautifully constructed apparatus, which enabled him to measure very minute quantities of carbon dioxide given off from small areas of the upper and under sides of a respiring leaf, and also to determine the relative intake of carbon dioxide by the two surfaces during assimilation in air artificially charged with that gas. The conclusions drawn are that respiratory egress, and assimilatory ingress of carbon dioxide, do not occur in the upper side of a leaf if this is devoid of stomatic openings, and that when these openings exist on both the upper and under sides the gaseous exchanges of both physiological processes are directly proportional to the number of stomata on equal areas; hence in all probability the exchanges take place only through the stomata. These observations of Mr. Blackman are of such far-reaching importance, and lead to such remarkable conclusions with regard to the rate of diffusion of atmospheric carbon dioxide, that we felt constrained to inquire into the matter further, and for this purpose we employed a modified form of the apparatus which we have used throughout our work on assimilation. Our results, on the whole, are decidedly confirmatory of Mr. Blackman's observations. The side of a leaf which is devoid of stomatic openings certainly neither allows any carbon dioxide to escape during respiration, nor does it permit the ingress of that gas when the conditions are favourable for assimilation. On the other hand, when stomata exist on both the upper and under sides of a leaf, gaseous exchanges take place through both surfaces, and, as a rule, in some sort of rough proportion to the distribution of the openings. There is, however, under strong illumination, a greater intake of carbon dioxide through the upper surface than would be expected from a mere consideration of the ratio of distribution of the stomata. Nevertheless, the general connection between gaseous exchange and distribution of stomata is so well brought out that we must regard it as highly probable that these minute openings are the true paths by which the carbon dioxide enters and leaves the leaf. One of the most interesting problems connected with plant assimilation relates to the efficiency of a green leaf as an absorber and transformer of the radiant energy incident upon it. It is already well known that the actual amount of energy stored up in the products of assimilation bears a very small proportion to the total amount reaching the leaf; in other words, the leaf, regarded from a thermo-dynamic point of view, is a machine with a very low "economic coefficient." We require, however, to know much more than this, and to ascertain, amongst other things, how the efficiency of the machine varies under different conditions of isolation, and in atmospheres containing varying amounts of carbon dioxide. The measure of the two principal forms of work done within the leaf, the vaporisation of the transpiration water on the one hand, and the reduction of carbon dioxide and water to the form of carbohydrates on the other, can be ascertained by modifying our experiments in such a manner as to allow the transpiration water to be determined, as well as the intake of carbon dioxide.

ADDRESS IN GEOLOGY.

The Address in Section C, Geology, was delivered by the president, Sir Archibald Geikie, F.R.S., on Saturday, having been postponed so that visitors from the Continent might be present. After reviewing the hypotheses that have been put forward in previous years, the president said:—Until, therefore, it can be shown that geologists and palæontologists have misinterpreted their records, they are surely well within their logical rights in claiming as much time for the history of this earth as the vast body of evidence accumulated by them demands. So far as I have been able to form an opinion, 100 millions of years would suffice for that portion of the history which is registered in the stratified rocks of the crust. But if the palæontologists find such a period too narrow for their requirements, I can see no reason on the geological side why they should not be at liberty to enlarge it as far as they may find to be needful for the evolution of organised existence on the globe. Referring then to the

Future Problems of Geology,

Sir A. Geikie said we may, therefore, well leave the dispute about the age of the earth to the decision of the future. In so doing, however, I should be glad if we could carry away from it something of greater service to science than the consciousness of having striven our best in a barren controversy, wherein concession has all to be on one side and the selection of arguments entirely on the other. During these years of prolonged debate I have often been painfully conscious that in this subject, as in so many others throughout the geological domain, the want of accurate numerical data is a serious hindrance to the progress of our science. The subject is too vast for adequate treatment here. But let me illustrate my meaning by selecting a few instances where the adoption of these more rigid methods of inquiry might powerfully assist us in dealing with the rates of geological processes and the value of geological time. Take, for example, the wide range of lines of investigation embraced under the head

of Denudation. A little consideration will show that in all branches of the investigation of denudation opportunities present themselves on every side of testing. By accurate instrumental observation and measurement, the rate at which some of the most universal processes in the geological régime of our globe are carried on. What we need is a carefully-organised series of observations carried out on a uniform plan, over a sufficient number of years, not for one river only, but for all the important rivers of a country, and indeed for all the greater rivers of each continent. The whole geological régime of each river should be thoroughly studied. Again, the action of glaciers has still less been subjected to prolonged and systematic observation. The few data already obtained are so vague that we may be said to be still entirely ignorant of the rate at which glaciers are wearing down their channels and contributing to the denudation of the land. The whole of this inquiry is eminently suitable for combined research. Nor is our information respecting the operations of the sea much more precise. The disintegration of the surface of the land by the combined agency of the subaërial forces of decay is a problem which has been much studied, but in regard to whose varying rates of advance not much has been definitely ascertained. The conditions under which subaërial disintegration is effected in arid climates and the rate of its advance are still less known, seeing that most of our information is derived from the chance observations of passing travellers. Closely linked with the question of denudation is that of the disposition of the material worn away from the surface of the land. We have yet to discover the different rates of deposit, under the varying conditions in which it is carried on in lakes, estuaries, and the sea. More momentous in their consequences are the disturbances which traverse mountain chains and find their most violent expression in shocks of earthquake. The effects of such shocks have been studied and recorded in many parts of the world, but their cause is still little understood. Are the disturbances due to a continuation of the same operation which at first gave birth to the mountains? Should they be regarded as symptoms of growth or of collapse? Are they accompanied with even the slightest amount of elevation or depression? We cannot tell. But these questions are probably susceptible of some more or less definite answer, and they might furnish us with suggestive information as to the rate at which upheaval or depression of the terrestrial crust is now going on. The vexed questions of the origin of raised beaches and sunk forests might in like manner be elucidated by well-devised measurements, for it is astonishing upon what loose and unreliable evidence the elevation or depression of coast-lines has often been asserted.

The president then mentioned the importance of the

Organisation of Research,

and said that the International Geological Congress, which brings together our associates from all parts of the globe, would confer a lasting benefit on the science if it could organise a system of combined observation in any single one of the departments of inquiry indicated, or in any other which might be selected. We need not at first be too ambitious. The simplest, easiest, and least costly series of observations might be chosen for a beginning. The work might be distributed among the different countries represented in the Congress. Each nation would be entirely free in its selection of subjects for investigation, and would have the stimulus of co-operation with other nations in its work. The congress will hold its triennial gathering next year in Paris, and if such an organisation of research as I have suggested could then be inaugurated, a great impetus would thereby be given to geological research, and France, again become the birthplace of another scientific movement, would acquire a fresh claim to the admiration and gratitude of geologists in every part of the globe.

ADDRESS IN ZOOLOGY.

The Address in Section D, Zoology, was delivered by Mr. Adam Sedgwick, F.R.S., who said in the course of his remarks, as everyone knows, there is a vast number of different kinds of organisms. Each kind constitutes a species, and consists of an assemblage of individuals which resemble one another more closely than they do other animals, which transmit their characteristics in reproduction and which habitually live and breed together. But the members of a species, though resembling one another more closely than they resemble the members of other species, are not absolutely alike. They present differences, differences which make themselves apparent even in members of the same family—i.e., in the offspring of the same parents. It is these differences to which we apply the term variation. The immense importance of the study of variations may be judged from the fact that, according to the generally-received evolution theory of Darwin, it is to them that the whole of the variety of living and extinct organisms is due. Without variation there could have been no progress, no evolution in the structure of organisms. If offspring had always exactly resembled their parents and presented no points of difference, each succeeding generation would have resembled those previously existing, and no change, whether backwards or forwards, could have occurred. This phenomenon of genetic variation forms the bedrock upon which all theories of evolution must rest, and it is only by a study of variations, of their nature and cause, that we can ever hope to obtain any real insight into the actual way in which evolution has taken place. Notwithstanding its importance, the subject is one which has scarcely received from zoologists the attention which it merits. According to the Darwinian theory of evolution, one of the most important factors in determining the modifications of organisms has been natural selection. Selection acts by preserving certain favourable variations, and allowing others less favourable to be killed off in the struggle for existence. It thus will come about that certain variations will be gradually eliminated. Meanwhile the variations of the selected organisms will themselves be submitted to selection, and certain of these will be in their turn eliminated. In this way a group of organisms becomes more and more closely adapted to its surroundings; and, unless new variations make their appearance as the old unfavourable ones are eliminated, the variability of the species will diminish as the result of selection. It would thus appear, and I think we are justified in holding this view, at any rate provisionally, that the result of continued selection will be to diminish the variability of a species, and, if carried far enough, to produce a race with so little variability, and so closely adapted to its surroundings, that the slightest alteration in the conditions of life will cause extinction. If selection tends to diminish the variability of a species, then it clearly follows that, as selection has been by hypothesis the most important means of modifying organisms, variation must have been much greater in past times than it is now. In fact, it must have been progressively greater the farther we go back from the present time. The argument which I have just laid before you points, if carried to its logical conclusion—and I see no reason why it should not be so carried—to the view that at the first origin of life upon the earth heredity was a much less important phenomenon than it is at present. Following out the same train of thought, we are inevitably driven to the conclusion that one of the most important results of the evolutionary change has been the gradual increase and perfection of heredity as a function of organisms and a gradual elimination of variability. This view, if it can be established, is of the utmost importance to our theoretical conception of evolution, because it enables us to bring our requirements as to time within the limits granted by the physicists. If variation was markedly greater in the early periods of the existence of living matter, it is clear that it would have been possible for evolutionary change to have been effected much more rapidly than at present—especially when we remember that the world was then comparatively unoccupied by organisms, and that, with the change of conditions consequent on the cooling and differentiation of the earth's surface, new places suitable for organic life were continually being formed.

ADDRESS IN GEOGRAPHY.

The Address in Section E, Geography, was delivered by Sir John Murray, F.R.S., and dealt mainly with the "Ocean Floor," which, he said, lies, for rather more than about a half, at a depth of 2,000 fathoms, or rather more. Depths exceeding 5,000 fathoms have been hitherto recorded only within the Aldrich Deep of the South Pacific, to the east of the Kermadees and Friendly Islands, where the greatest depth is 5,155 fathoms, or 530ft. more than five geographical miles, being about 2,000ft. more below the level of the sea than the summit of Mount Everest, in the Himalayas, is above it. Our knowledge of the temperature on the floor of the ocean is derived from observations in the layers of water immediately above the bottom by means of deep-sea thermometers, from the electric resistance of telegraph cables resting on the bed of the great ocean-basins, and from the temperature of large masses of mud and ooze brought up by the dredge from great depths. These observations are now sufficiently numerous to permit of some general statements as to the distribution of temperature over the bottom of the great oceans. All the temperatures recorded up to the present time in the sub-surface waters of the open ocean indicate that at a depth of about 100 fathoms seasonable variation of temperature disappears. Beyond that depth there is a constant, or nearly constant, temperature at any one place throughout the year. It is estimated that 92 per cent of the entire sea-floor has a temperature lower than 40° Fahr. This is in striking contrast to the temperature prevailing at the surface of the ocean, only 16 per cent. of which has a mean temperature under 40° Fahr. The temperature over nearly the whole of the floor of the Indian Ocean in deep water is under 35° Fahr. A similar temperature occurs over a large part of the South Atlantic and certain parts of the Pacific, but at the bottom of the North Atlantic basin and over a very large portion of the Pacific the temperature is higher than 35° Fahr. In depths beyond 2,000 fathoms the average temperature over the floor of the North Atlantic is about 2° Fahr. above the average temperature at the bottom of the Indian Ocean and South Atlantic, while the average temperature of the bed of the Pacific is intermediate between these. The deep sea is a region of darkness as well as of low temperature, for the direct rays of the sun are wholly absorbed in passing through the superficial layers of water. Plant-life is in consequence quite absent over 93 per cent. of the bottom of the ocean, or 66 per cent. of the whole surface of the lithosphere. The abundant deep-sea fauna, which covers the floor of the ocean, is therefore ultimately dependent for food upon organic matter assimilated by plants near its surface, in the shallower waters near the coast lines, and on the surface of the dry land itself. It thus happens that at the present time over nearly the whole floor of the ocean we have mingled in the deposits the remains of organisms which had lived under widely different physical conditions, since the remains of organisms which lived in Tropical sunlight, and in water at a temperature above 80° Fahr. all their lives now lie buried in the same deposit on the sea-floor together with the remains of other organisms which lived all their lives in darkness and at a temperature near to the freezing-point of fresh water. The marine deposits now forming over the floor of the ocean present many interesting peculiarities according to their geographical and bathymetrical position. On the continental shelf within the 100-fathom line sands and gravels predominate, while on the continental slopes beyond the 100-fathom line blue muds, green muds, and red muds, together with volcanic muds and coral muds prevail, the two latter kinds of deposits being, however, more characteristic of the shallow water around oceanic islands. The composition of all these terrigenous deposits depends on the structure of the adjoining land. In them the evidences of the mechanical action of tides, of currents, and of a great variety of physical conditions may almost everywhere be detected, and it is possible to recognise an accumulation of materials analogous to many of the marine stratified rocks of the continents, such as sandstones, quartzites, shales, marls, greensands, chalks, limestones, conglomerates, and volcanic grits. With increasing depth and distance from the continents the deposits gradually lose their terrigenous character, the particles derived directly from the emerged land decrease in size and in number, the evidences of mechanical action disappear, and the deposits pass slowly into what have been called pelagic deposits at an average distance of about 200 miles from continental coast lines. Our knowledge of the marine deposits is limited to the superficial layers; as a rule the sounding-tube does not penetrate more than 6in. or 8in., but in some positions the sounding tube and dredge have been known to sink fully 2ft. into the deposit. Sometimes a red clay is overlaid by a globigerina ooze, more frequently a red clay overlies a globigerina ooze, the transition between the two layers being either abrupt or gradual. In some positions it is possible to account for these layers by referring them to changes in the condition of the surface waters, but in other situations it seems necessary to call in elevations and subsidences of the sea-floor. There is a striking difference between the average chemical and mineralogical composition of terrigenous and pelagic deposits. It would be extremely interesting to have a detailed examination of one of those deep holes where a typical red clay is present, and even to bore some depth into such a deposit, if possible, for in these positions it is probable that not more than a few feet of deposit have accumulated since the close of the Tertiary period. One such area lies to the south-west of Australia, and its examination might possibly form part of the programme of the approaching Antarctic explorations. It has already been stated that plant-life is limited to the shallow waters, but fishes and members of all the invertebrate groups are distributed over the floor of the ocean at all depths. The majority of these deep-sea animals live by eating the mud, clay, or ooze, or by catching the minute particles of organic matter which fall from the surface. It is probably not far from the truth to say that three-fourths of the deposits now covering the floor of the ocean have passed through the alimentary canals of marine animals. These mud-eating species, many of which are of gigantic size when compared with their allies living in the shallow coastal waters, become in turn the prey of numerous rapacious animals armed with peculiar prehensile and tactile organs. Many deep-sea animals present archaic characters; still the deep sea cannot be said to contain more remnants of faunas which flourished in remote geological periods than the shallow and fresh waters of the continents. Indeed, king-crabs, lingulas, trigonias, Port Jackson sharks, *Ceratodus*, *Lepidosiren*, and *Protopterus* probably represent older faunas than anything to

be found in the deep sea. Sir Wyville Thomson was of opinion that, from the Silurian period to the present day, there had been as now a continuous deep ocean with a bottom temperature oscillating about the freezing-point of fresh water, and that there had always been an abyssal fauna. I incline to the view that in Palæozoic times the ocean basins were not so deep as they are now; that the ocean then had throughout a nearly uniform high temperature, and that life was either absent or represented only by bacteria and other low forms in great depths, as is now the case in the Black Sea, where life is practically absent beyond 100 fathoms, and where the deeper waters are saturated with sulphuretted hydrogen.

ADDRESS IN ECONOMIC SCIENCE AND STATISTICS.

The Address in Section F, Economic Science and Statistics, was delivered by Mr. Henry Higgs, who, in the course of his remarks said:—The prime concern of the economist and of the statistician is the condition of the people. Other matters which engage their attention—particular problems, questions of history, discussions of method, developments of theory—all derive their ultimate importance from their bearing upon the central subject. The statistician measures the changing phenomena of the production, distribution, and consumption of wealth, which to a large extent reflect and determine the material condition of the people. The economist analyses the motives of these phenomena, and endeavours to trace the connection between cause and effect.

Defects of Household Management.

The condition of the people has improved, and is improving, said Mr. Henry Higgs. Public hygiene has made great progress, and houses are better and more sanitary, though for this and other reasons rents have risen. Wages are higher. Commodities are cheaper. Co-operation and the better organisation of retail business giving no credit have saved some of the profits of middlemen for the benefit of the consumer, while authority fights without ceasing against frauds in weights and measures, and adulteration. Free libraries, museums, picture galleries, parks, public gardens, and promenades have multiplied, and it is almost sufficient to observe that no one seems to be too poor to command the use of a bicycle. But with all this progress it is to be feared that housekeeping is no better understood than it was two centuries ago—perhaps even not so well. If we were suddenly swallowed up by the ocean it appears probable that the foreign student would find it easier to describe from existing documents the life and home of the British craftsman in the Middle Ages than of his descendant of to-day. In part, no doubt, our fiscal system, with its few taxes upon articles of food, and its light pressure on the working classes, is responsible for this neglect. During the Napoleonic war Pitt sent for Arthur Young to ask him what were the ordinary and necessary expenses of a workman's family, and the question would again become one of practical politics if any large addition were required in the proceeds of indirect taxation. Taxation has the one advantage of providing us with statistics. But the details of consumption are still obscure. But when we travel abroad we are curious to notice, and do notice, without giving offence, the dress, the habits, and the food of peasants and workmen; and it is difficult to resist the conclusion that we are less observant at home because these common and trivial details appear to us unworthy of attention. In his "Principles of Economics" Prof. Marshall says:—"Perhaps £100,000,000 annually are spent even by the working classes, and £400,000,000 by the rest of the population of England in ways that do little or nothing towards making life nobler or truly happier." And, again, speaking before the Royal Statistical Society in 1893—"Something like the whole Imperial revenue, say 100 millions a year, might be saved if a sufficient number of able women went about the country and induced the other women to manage their households as they did themselves." These figures show, at any rate, the possibilities of greatness in the economic progress which may result from attention to the humblest details of domestic life.

Consumption of Coal.

After some remarks on the consumption of food, Mr. Higgs spoke about the coal and waste:—Mr. Sargant says, "It is impossible to say how much of the superiority of English health and longevity is owing to the use of open fireplaces; probably a considerable part is owing to it. It may be true that three-fourths of the heat of our fireplaces passes up the chimney and is lost to us; but we gain far more advantage by the fresh air constantly introduced into the room." At a former meeting of this Association Mr. Edward Atkinson exhibited a portable oven or cooking-stove, which was a marvel of simplicity and economy. He has described it at length in his "Science of Nutrition," 1892. He argues that the attempts to combine cooking with the warming of a room or house are absurdly wasteful; that almost the whole of the fuel used in cooking is wasted; and that nine-tenths of the time devoted to watching the process of cooking is wasted; and he estimates the waste of food from bad cooking in the United States at 1,000,000,000 dollars a year. I have not, however, heard of his oven being at all extensively used. Upon the thorny subject of dress it is perilous to venture; but it is impossible to be in the neighbourhood of a London park on a Sunday afternoon without feeling that the efforts of domestic servants to follow the rapidly changing vagaries of fashion are carried to a pernicious degree of waste. The blouse of the French workman and the bare head of the Parisian factory girl or flower girl are infinitely more pleasing than the soiled and frowsy woollens or the dowdy hats of their English fellows; nor does the difference of climate afford an adequate explanation of the difference of habit. We must perhaps admit a greater dislike in England to any external indication of a difference in wealth by a costume different in kind. M. Levollée, after referring to the low price of the ready-made suits which the English factories "fling by the million on the markets of the world, including their own," adds: "This extraordinary cheapness is, however, not always without inconvenience to the consumer. If the clothes he buys cost little, they are not lasting, and their renewal becomes in the long run very burdensome. This renewal is, too, the more frequent in that the wife of the English workman is in general far from skilful in sewing and mending. Whether she lacks inclination or the necessary training, or whether the fatigues of a too frequent maternity make her *rôle* as a housewife too difficult for her to support, the woman of the people is generally, on the other side of the Channel, a rather poor cook, an indifferent needlewoman, and a still more indifferent hand at repairs." Given an equal income, there is probably no doubt that a French working-class family will be better fed and better clad than a corresponding English family dealing in the same market, and will lay up a larger stock of the household goods, and especially linen, which are the pride of the French peasant. It is not suggested that every man should confine his expenditure to what is strictly necessary to maintain his social position. Le Play refers to tobacco as "the most economical of all recreations." How else, he asks, could the Hartz miner "give himself an agreeable sensation" a thousand times in a year at so low a cost as 10*f*.?

ADDRESS IN MECHANICAL SCIENCE.

The Address in Section G was delivered by Sir W. H. White, F.R.S., who spoke mainly about steam navigation at high speeds, saying that steamship design to be successful must always be based on experiment and experience as well as on scientific principles and processes. It involves problems of endless variety and great complexity. The services to be performed by steamships differ in character, and demand the production of many distinct types of ships and propelling apparatus. In all these types, however, there is one common requirement—the attainment of a specified speed. And in all types there has been a continuous demand for higher speed. Stated broadly, the task set before the naval architect in the design of any steamship is to fulfil certain conditions of speed in a ship which shall not merely carry fuel sufficient to traverse a specified distance at that speed, but which shall carry a specified load on a limited draught of water. Speed, load, power, and fuel supply are all related; the last two have to be determined in each case. In some instances other limiting conditions are imposed affecting length, breadth, or depth. In all cases there are three separate efficiencies to be considered; those of the ship, as influenced by her form; of the propelling apparatus, including the generation of steam in the boilers and its utilisation in the engines; and of the propellers. Besides these considerations, the designer has to take account of the materials and structural arrangements which will best secure the association of lightness with strength in the hull of the vessel. He must select those types of engines and boilers best adapted for the service proposed. Here the choice must be influenced by the length of the voyage, as well as the exposure it may involve to storm and stress. Obviously, the conditions to be fulfilled in an ocean-going passenger steamer of the highest speed and in a cross-Channel steamer designed to make short runs at high speed in comparatively sheltered waters must be radically different. And so must be the conditions in a swift sea-going cruiser of large size and great coal endurance from those best adapted for a torpedo-boat or destroyer. There is, in fact, no general rule applicable to all classes of steamships; each must be considered and dealt with independently, in the light of the latest experience and improvements. Speaking of the progress made in steam propulsion, Sir W. H. White said:—Speed has been increased from 8½ to 22½ knots; the time on the voyage has been reduced to about 38 per cent. of what it was in 1840. Ships have been more than trebled in length, about doubled in breadth, and increased tenfold in displacement. The number of passengers carried by a steamship has been increased from about 100 to nearly 2,000. The engine power has been made nearly 40 times as great. The ratio of horse-power to the weight driven has been increased fourfold. The rate of coal consumption (measured per horse-power per hour) is now only about one-third what it was in 1840. To drive 2,000 tons weight across the Atlantic at a speed of 8½ knots about 550 tons of coal were then burnt; now, to drive 20,000 tons across at 22 knots about 3,000 tons of coal are burnt. With the low pressure of steam and heavy slow-moving paddle-engines of 1840, each ton weight of machinery, boiler, &c., produced only about 2H.P. for continuous working at sea. With modern twin-screw engines and high steam pressure, each ton weight of propelling apparatus produces from 6H.P. to 7H.P. Had the old rate of coal consumption continued, instead of 3,000 tons of coal, 9,000 tons would have been required for a voyage at 22 knots. Had the engine been proportionately as heavy as those in use 60 years ago, they would have weighed about 14,000 tons. In other words, machinery, boilers, and coals would have exceeded in weight the total weight of the *Campania* as she floats to-day. There could not be a more striking illustration than this of the close relation between improvements in marine engineering and the development of steam navigation at high speeds. In many ways, and particularly in regard to machinery design, the construction of torpedo vessels has greatly influenced that of larger ships. One important consideration must not be overlooked. For short-distance steaming at high speeds economy in coal consumption is of little practical importance, but it is all-important to secure lightness of propelling apparatus in relation to power. For long-distance steaming, on the contrary, economy in coal-consumption is of primary importance; and savings in weight of propelling apparatus, even of considerable amount, may be undesirable if they involve increased coal consumption. Differences of opinion prevail as to the real economy of fuel obtainable with boilers and engines such as are fitted in torpedo vessels. Claims are made for some vessels which represent remarkable economy. Only enlarged experience can settle these questions. Endurance is also an important quality in sea-going ships of large size, not merely in structures, but in propelling apparatus. The extreme lightness essential in torpedo vessels obviously does not favour endurance if high powers are frequently or continuously required. Still, it cannot be denied that the results obtained in torpedo vessels show such a wide departure from those usual in sea-going ships as to suggest the possibility of some intermediate type of propelling apparatus applicable to large sea-going ships and securing sufficient durability and economy of fuel in association with further saving of weight. Referring to the

Possibilities of Increased Speed,

Sir W. H. White said it would be idle to attempt any prediction as to the characteristic features of ocean navigation 60 years hence. Radical changes may well be made within that period. Further reductions may be anticipated in the weight of propelling apparatus and fuel in proportion to the power developed; further savings in the weight of the hulls, arising from the use of stronger materials and improved structural arrangements, improvements in form, and enlargement in dimensions. If greater draughts of water can be made possible so much the better for carrying power and speed. For merchant vessels commercial considerations must govern the final decision; for warships the needs of naval warfare will prevail. It is certain that scientific methods of procedure and the use of model experiments on ships and propellers will become of increased importance. Already avenues for further progress are being opened. For example, the use of water-tube boilers in recent cruisers and battleships of the Royal Navy has resulted in saving one-third of the weight necessary with cylindrical boilers of the ordinary type to obtain the same power with natural draught in the stokeholds. Differences in opinion prevail, no doubt, as to the policy of adopting particular types of water-tube boilers; but the weight of opinion is distinctly in favour of some type of water-tube boiler in association with the high steam pressures now in use. Greater safety, quicker steam-raising, and other advantages, as well as economy of weight, can thus be secured. Some types of water-tube boilers would give greater saving in weight than the particular type used in the foregoing comparison with cylindrical boilers. Differences of opinion prevail also as to the upper limit of steam pressure which can with advantage be used, taking into account all the conditions in both engines and boilers. From the nature of the case increases in pressure beyond the 160lb. to 180lb. per square inch commonly reached with cylindrical boilers cannot have anything like the same effect upon economy of fuel as the corresponding increases have had, starting from a lower

pressure. Some authorities do not favour any excess above 250lb. per square inch on the boilers; others would go as high as 300lb., and some still higher.

ADDRESS IN ANTHROPOLOGY.

The Address in Section H, Anthropology, was delivered by Mr. C. H. Read, who spoke of the importance of preserving our "prehistoric antiquities." Many ancient remains, such as the barrows of the early Bronze Age, are altogether unrecognised as such, and in the process of cultivation have been ploughed down almost to the level of the surrounding surface, until at last the plough scatters the bones and other relics unnoted over the field, and one more document is gone that might have served in the task of reconstructing the history of early man in Britain. Such accidental and casual destruction is, however, probably unavoidable, and, being so, it is scarcely profitable to dwell upon it. We can, perhaps, with more advantage protest against wilful destruction, whether it be wanton mischief or misplaced archæological zeal. An enlightened public opinion is our only protection against the first of these, and will avail against the second also; but we are surely entitled to look for more active measures in preventing the destruction of archæological monuments in the name of archæology itself. It is a far more common occurrence than is generally realised for a tumulus to be opened by persons totally unqualified for the task either by experience or reading. The loss that science has suffered by this indiscriminate and ill-judged exploration is difficult to estimate. Experience teaches us that it is not to State control that we must look. We must look to private organisations, and preferably to those already in existence, for some effectual moral influence and control, and, in my judgment, the appeal could best be made to the local scientific societies. The plan I would propose is this. Each society should record on the large-scale ordnance map every tumulus or earthwork within the county, and at the same time keep a register of the sites with numbers referring to the map, and in this register should be noted the names of the owner and tenant of the property, as well as any details which would be of use in exploring the tumuli. I am well aware that a survey of this kind has been begun by the Society of Antiquaries of London, and is still in progress; but this is of a far more comprehensive character, and is, moreover, primarily intended for publication. The more limited survey I now advocate would in no way interfere with it; but, on the contrary, would provide material for the other larger scheme. Once the local society is in possession of the necessary information just referred to, it would be the duty of its executive to exercise a beneficent control over any operations affecting the tumuli, and it may safely be said that such control could in no way be brought to bear so easily and effectively as through a local society.

ADDRESS IN PHYSIOLOGY.

The Address in Section I was delivered by Mr. J. N. Langley, F.R.S., the subject being the relation of the motor nerves to the tissues of the body, which, as Lord Lister said, is one of "intense and universal interest." The president of the section (Mr. Langley), in the course of his remarks, said:—From the early part of this century one way of regarding the body has been to consider it as made up of tissues grouped together in varying number and amount. Each tissue has its characteristic features under the microscope, and the point I wish to lay stress on is that in any broad classification not more than two tissues are known to be supplied with approximate completeness with different nerve-fibres. The striated muscular tissue, which forms, amongst other parts of the body, the muscles of the limbs and trunk, receives in all regions nerve-fibres from the brain or spinal cord. And the unstriated muscular tissue, which forms, amongst other parts of the body, the contractile part of the alimentary canal, and of the blood-vessels, is in nearly, and possibly in all, regions similarly supplied. According to our present state of knowledge large portions of the organism live their own lives uninfluenced, except indirectly, by the storms and stresses of the central nervous system. No nervous impulse can pass to them to make them contract, or to make them secrete, or to quicken or slacken their inherent activity. The nervous system can only influence them through the medium of some other tissue by changing the quantity or quality of the surrounding fluid. Regarding, then, the body from the point of view of the control exercised by the nervous system on the other constituents, we have first to recognise that this control is in considerable part indirect only; that the several tissues are in varying degree under direct control, and that different parts of one tissue may be influenced by the nervous system to different extents. Even when nervous impulses can strikingly affect the vital activity of a tissue, their action is limited. They cannot modify the activity in all the various ways in which it is modified by the inherent nature of the tissue and the character of the surrounding fluid. Thus the sub-maxillary gland which pours saliva into the mouth is in life ceaselessly taking in oxygen and giving out carbonic acid; it does this without pouring forth any secretion. So far as we know no nervous impulse can hasten or retard this customary life of the gland by a direct action upon it without producing other changes. The essential effect of a nerve impulse appears to be to modify the amount of energy set free as work; usually it causes work to be done, as in the contraction of a muscle, or in the secretion of fluid by a gland; sometimes it diminishes the work done, as in the cessation of a heart-beat, or the decrease of contraction of a blood-vessel. Other changes often go on side by side with this setting free of energy as work; but there is no unimpeachable instance in which these other changes take place by themselves as the result of nervous excitation. The somatic or voluntary nervous system has in its essential features long been known; we may, therefore, pass on to the more obscure field of the arrangement of the involuntary nervous system which presents some peculiar characters. The most distinctive of these is that the nerves, after they leave the brain or spinal cord, do not run interruptedly to the periphery; they end in nerve-cells, and the nerve-cells send off the fibres which run to the periphery. Thus all nerve-impulses, which pass from the brain or spinal cord to unstriated muscle or glandular tissue, pass through an intermediate station on their way. In this, as in some other respects, the arrangement of the involuntary nervous system is more complex than that of the voluntary nervous system; in the latter the motor nerve-fibres run direct to the tissue, and have no nerve-cells on their course.

ADDRESS IN BOTANY.

The Address in Section K, Botany, was delivered by Sir George King, and was mainly devoted to the history of Indian botany, which was commenced by the Dutch in the "Hortus Malabarensis." After referring to the work done by Sir Joseph Hooker, Roxbrough, Wallich, and that "most remarkable man" William Griffith, the president pointed out that the bulk of the work of elaborating the materials sent from India must be done in a large Herbarium, such as did not exist in Asia. In the Kew Herbarium were to be found the types of an overwhelming proportion of the new species described for the first time in that monumental work, "The Flora of British India." "The preservation in good condition of a type specimen is, from the point of view of a systematic botanist, as important as is the preservation to the British merchant of the standard pound weight and the standard yard measure on which the operations of British commerce depend. 'Types' also stand to the systematic botanist much in the same relation as the national records do the national historian. The latter are guarded in the Record Office, I understand, with all the skill which the makers of fire-proof, damp-proof, and burglar-proof depositories can suggest. If, however, the type of a species happens to be deposited at Kew, what are the probabilities of its preservation? Such a type at Kew is incorporated in what is admitted to be in every sense the largest and, for its size, the most accurately named, the most easily consulted, and therefore the most valuable Herbarium in the world, the destruction of which would be a calamity commensurate in extent with that of the burning of the library at Alexandria. One might therefore reasonably expect that a people who rather resent being called a 'nation of shopkeepers' would feel pride in providing for this priceless national collection a home which, although perhaps somewhat inferior to that provided for the national historical records, might at least be safe from fire. This expectation is not fulfilled. The infinitely valuable Kew Herbarium and library have no safer home than an old dwelling-house on Kew-green, to which a cheap additional wing has been built. The floor, galleries, and open inner roof of this additional wing are constructed of pine coated with an inflammable varnish, and on the floor and galleries are arranged cabinets (also made of pine-wood), in which the specimens (which are mounted on paper) are lodged. On behalf of the Flora of India, I venture to express the hope that the provision of a proper home for its types may receive early and favourable consideration by the holders of the national purse-strings. But India is by no means the only portion of the Empire interested in this matter, and the safe custody of the Kew Herbarium is not merely a national, but a cosmopolitan responsibility."

ABSTRACTS OF REPORTS, PAPERS, &c.

Masses Smaller Than Atoms.

A paper giving an account of recent researches on the "Existence of Masses Smaller than Atoms" was read by Prof. J. J. Thomson, F.R.S., in which he pointed out that several lines of investigation lead to a determination of the ratio of the mass of an atom to the electric charge conveyed by it. These are (1) ordinary electrolysis; (2) experiments on the velocity of charged particles; (3) experiments on the velocity of cathode discharges. The result of these experiments indicates that the charge carried by an atom in cathode discharges and similar phenomena is apparently 1,000 times greater than in ordinary electrolysis. It follows either that the atoms become dissociated and only a portion of their mass carries the negative charges of cathode rays, or else that the atom can receive a greater charge than is assigned to it in explaining electrolytic phenomena; either the mass is smaller or the charge greater than in the case of electrolysis. The author described a method of discriminating between these two assumptions by determining separately the charge carried by a known number of atoms, in a case for which the charge per unit mass has the greater value. The method used consists in deflecting by a magnetic field the paths of particles which convey the negative charge from a flat plate to a close parallel one, under the action of ultra-violet light. A flat metal plate, negatively electrified, is brought near to a very large perforated metal plate through which ultra-violet radiation can pass, the whole apparatus being inclosed in gas at a pressure of about 1-100 millimètre of mercury. The radiation causes a discharge of electrified particles from the negative plate, which move in parallel straight lines to the perforated plate which receives their charge. If now a magnetic field be set up between the plates, its direction being parallel to the plane of the plates, the paths of the particles become curved—in fact, cycloids, and the particles may not reach the perforated plate if the latter is far enough away from the negative plate. There will therefore be a diminution in the rate of discharge, which is the phenomenon actually observed; its amount corresponds with theory if we assume the large value of the charge per unit mass. The magnitude of the phenomenon is the same in all gases and the same for ultra-violet and cathode rays. Similar results are obtained for observing the negative charges leaving an incandescent electric filament of carbon in an atmosphere of hydrogen in a magnetic field. The amount of charge carried by an atom depends on the gas and on the nature of the electrodes. It would appear from this, although he put the theory forward with diffidence, that electrification seems to consist in the removal from an atom of a small corpuscle, the latter consisting of a very small portion of the mass of the atom with a negative charge, while the remainder of the atom possesses a positive charge. This assumption favours Prout's hypothesis that the mass of an atom is not invariable, a supposition confirmed by the recent spectroscopic determinations of Lockyer and others. —M. Broca described some experiments confirming the conclusions of Prof. Thomson. He had obtained, in a Crookes vacuum-tube, with small platinum electrodes half a millimètre apart, an actual spark. The metal from the anode deposited on the walls of the tube and its path could be deflected by a magnetic field, as if it carried a positive charge. Spectroscopic analysis of the spark near the two electrodes confirmed Prof. Thomson's results.

Physical Conditions of the English Channel.

The recorder of Section D, Zoology, Mr. Garstang, presented the first report of the committee on the "Periodic Investigation of the Plankton and Physical Conditions of the English Channel during 1899." He said that the proposed investigation had been carried on by him at regular intervals during the year. Practically the whole of the grant had been devoted to the hire of a suitable steam-boat for the survey, and two further cruises would be necessary to complete the investigation. The observations of temperature and salinity and the collections of plankton obtained would furnish a complete year's record of the periodic changes in the physical character of the water, and in the quantity and character of the floating flora and fauna in the mouth of the English Channel. This standing record should be of the highest value in many branches of marine biological and hydrographic inquiry. Most of the apparatus used was the property of the Marine Biological Association, which had borne all the expense of the special nets and gear. The Royal Society Grant Committee had also lent apparatus. Mr. Garstang concluded by showing and explaining the special nets which he had devised for his investigation.—Prof. Ray Lankester, F.R.S., as president of the Marine Biological Association, congratulated Mr. Garstang on the results he had obtained. Baron Jules de Guerne, who has been conducting similar investigations from the yacht of the Prince of Monaco, commended the simplicity of Mr. Garstang's net. He explained that those used by himself had been far more elaborate, but had not given quite satisfactory results.

Electrolysis and Electro-Chemistry.

The report of the committee on electrolysis and electro-chemistry was presented by Mr. W. C. D. Whetham. It states that the conductivity of a number of salts in very dilute aqueous solution at

the freezing-point of water has been determined by Mr. Whetham, while Mr. Griffiths has concurrently made observations of the freezing-point for corresponding solutions. The observations of conductivity extend to solutions of sulphuric acid, potassium chloride, sodium chloride, barium chloride, copper sulphate, potassium permanganate, potassium bichromate, and potassium ferricyanide. The range of dilution is, speaking generally, from below the hundredth-thousand to about the twentieth part of a gram equivalent per thousand grams of solution. The water used was specially distilled three times, in the last instance from a platinum still, and collected in platinum vessels. Its specific resistance was rather smaller than that of the water obtained by Kohlrausch by distillation in vacuo. The results obtained this year, while confirming those described at the last meeting of the Association for solutions of moderate concentrations, show differences when great dilutions are reached, but the constancy of the present measurements shows that the water now used is good enough to enable trustworthy values to be obtained even at the lowest limits of dilution above mentioned.—Mr. E. H. Griffiths, F.R.S., stated that he had met with great difficulties in his experiments on freezing-points of solutions, though he believed he had now located the source of error in the results—namely, the absorption of gases by the solutions. He could measure easily a difference of temperature of five-millionths of a degree Centigrade.

Heat of Combination of Metals.

The report of the committee on the heat of combination of metals in the formation of alloys, was read by Prof. O. J. Lodge, F.R.S. The experiments have been carried out by Dr. A. Galt in order to determine whether the heat produced by the solution of an alloy of copper and zinc in nitric acid is the same as would be produced by the solution of the same amount of copper and zinc mixed, but not alloyed. The results show that the heat of combination of zinc and copper is negative when much zinc is present and becomes a negative maximum for 16 per cent. of copper. With greater percentages of copper the heat of combination becomes zero and then positive, reaching a maximum positive value for 38 per cent. of copper. It then sinks to zero, reaching that value for 90 per cent. of copper.—Mr. Vernon Harcourt, F.R.S., thought that great caution was necessary in making deductions from observations of this nature, because the products of decomposition of the acid used might be different according as the alloys or the mixed metals are used.

Stonehenge.

In Section H, Anthropology, Dr. Alfred Eddowes read a paper entitled "Stonehenge: Some New Observations and a Suggestion." Dr. Eddowes said he believed that the 30 large upright stones, with their intervals, indicated that the circle was divided into 60 equal parts; that the grooved stone (which was the best selected, worked, and preserved stone in the whole ruin, but had never hitherto received the attention it deserved) was used for supporting a pole in a definite and permanent manner; and that the signs of wear at the mouth of the groove, together with the two worn horizontal hollows or waists, and the dimples on the convex back of the stone, indicated not only where, but how, this pole was fixed. Such a pole would form the pointer of a sun-dial for daily observation, or, what was more important, an indicator of the time of year, by the length of its shadow. The levelled avenue (along which the sun's shadow would fall about 3p.m.) and the flat "slaughter-stone" with its arrow-head marking seemed to him to support his view.—Dr. Sebastian Evans thought that Dr. Eddowes had proved his point that Stonehenge had been used for the purposes of an observatory, and remarked that though there was a vast literature on the subject, yet the study of Stonehenge had hardly begun, for it had never been investigated as a part of a whole series of early stone monuments. Mr. Arthur Evans somewhat dissented from Dr. Eddowes's views. Observing that Stonehenge was on the site of remains of an early Bronze Age cemetery, he said it ought to be regarded not alone but in relation to a large series of other stone monuments, and he entered a protest against the attempt to introduce very precise and rigorous scientific ideas into what was, in his opinion, a rude monument.

Symbiosis.

In Section B, Chemistry, some interesting notes were read. Prof. Marshall Ward, F.R.S., first of all drew attention to various instances both in the vegetable and animal kingdom, where organisms existed together and performed functions helpful either to one or to all of the organisms concerned—functions, moreover, that were not performed in the absence of any of the contributory organisms. In some instances the organisms passed the whole of their existence together for their mutual advantage, as was the case with the alga and fungus constituting the dual organism of lichens. This he regarded as true symbiosis. In other cases the one organism appeared to prepare the way for the other, as for instance in the successive stages of the conversion of starch, first into sugar by a mould, and then into alcohol by yeast. For this sort of association he proposed the name metabiosis. But all stages of associations were to be found in nature up to the case where one organism injured the other. This state of affairs, which was exemplified by many parasites, had been termed antibiosis. In some circumstances, however, a condition of antibiosis might gradually become one of symbiosis. The aid rendered by one organism to another took various forms, such as the preparation of proper nutritive matter, the removal of injurious or noxious matter, or the formation of protective substance.—Sir Henry Roscoe, F.R.S., translated the "Note sur les Fermentations Symbiotiques Industrielles" presented by Dr. A. Calmette, director of the Pasteur Institute of Lille. In this paper particular attention was drawn to the conversion of starch into alcohol by means of the symbiotic existence of moulds with yeasts, and to its possible industrial application. Sir Henry remarked that this possibility had already been realised, for by the employment of pure cultivations of the two forms of organisms thousands of tons of starch were transformed into alcohol in France and Belgium. This state of things would revolutionise the industry of fermentation and distillation, inasmuch as under efficient scientific supervision the yield of spirit by the new process amounted to as much as 97½ per cent. of the theoretical yield. Moreover, the spirit was superior in quality to that produced in the ordinary way.—Prof. Armstrong, F.R.S., contributed a paper entitled "Symbiotic Fermentation: its Chemical Aspects." He advanced arguments in favour of the purely chemical character of symbiosis, and advocated in particular Baeyer's view that fermentative changes are due to the withdrawal of water and the subsequent addition of its elements in a different order, the function of enzymes being to bring the water to this particular condition of activity.

Coal in Kent.

A paper on "The South-Eastern Coalfield" was read by Prof. Boyd Dawkins, F.R.S., in the course of which he said:—The discovery was of great practical value, as it would probably result in the same development in Kent of industries and manufactures which had taken place where the coal had been worked, under the same conditions, under the cretaceous and jurassic rocks in France and Belgium. It was of equally great theoretical value, as it proved up to the hilt the truth of Godwin Austen's view, published in 1858, that the coal measures lie buried underneath the newer rocks in South-Eastern England. The first boring to be noticed was at Ropersole, a spot near the highway between Dover and Canterbury—eight miles from Dover, at 400ft. above O.D.—the surface being composed of upper chalk, with a thin stratum of clay-with-flints. It was begun at the close of 1897, and had at the present time pierced the strata to a depth of 1,773ft. 7in. In his opinion, the coal measures of Ropersole were a portion of the same series as those at Dover. Here, as at Dover, the question of seams of coal resolved itself probably into a question of sinking deeper. Here only two unimportant seams had been met with in a thickness of 197ft. There twelve seams were penetrated in a thickness of 1,054ft. 6in., the thickest 4ft. seam being at the bottom. The Ropersole boring established the fact that the Dover coal measures extended northwards for a distance of eight miles, and beyond in the direction of Canterbury. The coal measures set in in Kent at a sufficient distance to the north-east of Brabourne to allow of the presence of the carboniferous limestone and millstone grit. These probably dip at the same high angle as the Devonian below. Their south-western boundary could only be accurately defined by further borings, such as those which were now being carried on at Ottinge, about 2½ miles to the north-east of the scarp of the Downs, and six miles to the south-west of Ropersole. Their range to the north and the east still remained to be proved. They were, however, continued under the Channel, and had been proved by the boring at Calais in 1850, as well as those carried out in 1898 at Strouannes, near Wissant.—Some questions being asked, Mr. Etheridge replied that chemical analysis showed that the Dover coal was of the same quality as that found in the other fields; and Prof. Boyd Dawkins observed that there was good blazing coal, as well as steam coal and anthracite, found in South Wales exactly corresponding to that of Dover; that he had found no lignite in the Dover coal-measures, but some in the secondary rocks, the oolites, above; that no temperature observations were possible in the boring, and finally, in respect of the depths of the coal-measures, that he was of the opinion that the seams reached at Dover formed only the upper part of the measures, so thick at Westphalia, where they were 7,200ft. thick, and reached 7,600ft. at Liége.

Dover and Franco-Belgian Coalfields.

Mr. Etheridge said that the history of the stratified rocks of South-East Kent was now in a fair way of being fully determined. The Dover exploration was carried through the lower cretaceous, jurassic, and probably the upper series of the coal-measures, with, so far, eight seams of workable coal to the depth of 2,225ft. How many more seams there are was not certain, but over 100ft. of the coal-measures below the thick or 4ft. seam had been tested, and yet the coal-measure floor had not been penetrated. The discovery of these coal-measures proved completely Godwin Austen's view of forty years ago, that the coal-measures which form part of the line joining the coalfields of Westphalia, Belgium, and North France with those of Bristol, North Somerset, and South Wales lie buried beneath the newer rocks in South-East England. The future commercial value to Dover and its neighbourhood might be inferentially seen from the fact that in 1850 there were only two collieries in the Pas de Calais field, producing annually 19,000 tons, while in 1895 there were 17 collieries producing over 11,000,000 tons. Comparing by maps, plans, and statistics of borings the coalfields of Brabourne and Dover with those of Belgium and South Wales, Mr. Etheridge showed, first, that Prof. Prestwich's view was probably correct—namely, that the Dover field was one of a chain of isolated coal-basins that extended from Prussia to the South of Ireland, and passed under the Straits of Dover; then that the coal at Dover was workable at a depth comparing very favourably with (and, indeed, much less than) the depths worked in South Wales and Belgium.

Concealed Coalfields.

Mr. Walcot Gibson read a paper on some recent work among the Upper Carboniferous of North Staffordshire and its bearings on concealed coalfields. He observed that in his investigations he had met with workable seams of coal at reasonable depths beneath the red rocks surrounding the South Staffordshire coalfield; but there remained large areas lying between the known coalfields of Shropshire, North Staffordshire, and Nottinghamshire that had not at present been explored. Within the South Staffordshire area there were considerable areas of so-called permian rocks, which recent investigations had proved to be conformable to the upper coal measures and to contain a coal-measure flora. This determination would have important industrial bearings. The fact that the Newcastle limestone lay at the base of grey measures intercalated between an upper group of red strata (the Etruria marls) had enabled him to detect true coal measures in Keele-park, Shutlanehead, and to the west of Leycett. There was, moreover, little doubt that the coal measures of the Pottery coalfield lay not far from the surface under Little Madeley and Craddocks Moss. Evidence had been obtained that the strata on the north-west side of the North Staffordshire anticline did not uninterruptedly descend beneath the (so-called permian) red rocks to the west of Leycett, but rose locally westward under Hayes. The effect of this change of inclination was to bring to the surface strata which lay considerably below the unproductive red series, and to bring the principal coal and ironstones within reach further west than might have been expected. The conclusion he reached was that a thorough and complete examination of the exposed coalfields of the Midland counties and of the bordering New Red rocks would be of the highest importance in determining at what depth the productive measures lie beneath the great central tracts of the Midland counties. Prof. Lapworth congratulated Mr. Gibson on his very important work, and said that the conclusions he had reached from the practical observations made coincided with those that he himself had reached from theoretical deductions.

Solidification of Hydrogen.

A paper by Prof. Dewar, F.R.S., on "The Solidification of Hydrogen," in the absence of the author was read by Sir W. Crookes, F.R.S. Solid hydrogen presents the appearance of frozen water, and not, as has been anticipated by many, that of frozen mercury. The temperature of the solid is 16° absolute at 35 millimètres pressure, and it melts 16° or 17° absolute, the practical limit of temperature obtainable by its evaporation being 14° or 15° absolute.—Dr. Ludwig Mond, in proposing the vote of thanks, said it was gratifying to learn not only that Prof. Dewar had achieved this great result, but that he was still alive to tell the tale, for the danger incident to the experiments was considerable. Dr. Gladstone, F.R.S., in seconding the vote of thanks, remarked on this great triumph of Prof. Dewar, hydrogen being the last of the old gases that remained to be solidified. Sir W. Crookes, in acknowledging the vote of thanks, pointed out that the great danger in these experiments resulted from the leakage in of air, which made an explosive mixture with the hydrogen; furthermore, during the passage of the dry gas through the narrow tubes it became electrified, and in some instances sparking occurred with most violent detonation. Sir William also announced that Prof. Dewar had succeeded in liquefying helium by means of liquid hydrogen, an announcement that was received with acclamation. The hydrogen for these experiments was obtained by the action of pure sulphuric acid on pure zinc.

A Remarkable Sponge.

In the Section of Zoology, Mr. J. J. Lister read a

paper describing a new form of sponge, *Astrosclera Willeyana*, obtained by Dr. Willey at Lifu, in the Loyalty Islands. The features which render the sponge peculiar are a calcareous skeleton formed of polyhedral elements united together into a solid mass, which is penetrated by a system of canals containing the soft parts; the limitation of the canal system to the upper surface; the absence of large atrial spaces, and the minute size of the ciliated chambers (under 20-thousandths of a millimètre in diameter). In its larger characters the sponge presents considerable resemblance to the fossil *Pharetrones*, which are found in strata ranging from the Devonian to the Cretaceous. It differs from them, however, in the nature of skeletal elements. The sponge appears to form the type of a new family—the *Astroscleridæ*.—Prof. Sollas and Prof. Ray Lankester congratulated Mr. Lister on the work, whose results he had communicated, and Prof. Lankester stated that the discovery was one of the most remarkable of the year in biological science.

Origin of Flint.

The subject of the origin of flint was referred to by Prof. W. J. Sollas, F.R.S., who said that the first stage was the conversion of the calcareous remains of the organisms of the chalk into silica. The silicious foraminifera and coccoliths so produced were cemented by a deposition of silica into white flint, and this by a further deposit of silica became converted into black flint, just as snow might be transformed into compact ice. The source of the silica might be looked for in the remains of silicious organisms, such as sponge spicules, and Prof. Sollas said he was now able to bring positive proof of the original existence of abundant spicules in the chalk, which were now represented by hollow casts to the extent sometimes of 3 per cent. of the rock.

Permanence of Planetary Gases.

In a paper on the "Permanence of Certain Gases in the Atmospheres of Planets," Prof. G. H. Bryan, F.R.S., described an investigation of which the methods were indicated at the meeting of the Association in 1893, when he applied the kinetic theory of gases to explain the absence of an atmosphere from the moon's surface. In the present investigation similar methods were applied to the atmospheres of planets, account being taken of the axial rotations. A test of the permanence or otherwise of different gases in the atmospheres of different celestial bodies at different temperatures had been obtained, and a superior limit had been found for the rate at which any planet would lose any gas by the molecules flying off from its atmosphere. To interpret this limit in the simplest possible form he calculated the number of years which would have to elapse in various cases before the quantity of gas lost would be equivalent to that contained in a layer one centimètre thick covering the surface of the earth. In the case of terrestrial hydrogen the loss in question would occupy 84,000,000,000 years at temperature − 73°, 600,000 years at − 23°, and 222 years at 27° C. For helium on the earth's surface, the corresponding numbers were $3 \cdot 5 \times 10^{16}$ years at −73°, 3×10^{19}, or 30 trillion years at 27°, 84,000,000,000 years at 127°, 600,000 years at 227°, and 222 years at 327°. The removal of a layer of air one centimètre in thickness from the surface of the earth would only mean a lowering in the average barometric pressure of one-thirteen-thousand-six-hundredth of a millimètre, roughly. Suppose then that the afore-mentioned gases were present in the respective atmospheres in sufficient quantity to produce pressures comparable with one atmosphere, and assume that a fall of one millimètre in the average height of the barometer to be the least secular change that could be detected, the above-mentioned intervals of time would have to be multiplied by 13,600, roughly, in order to give the number of years in which the escape of the respective gases could be detected by a barometer. The only possible conclusions from these results were: (1) that helium could exist permanently in our atmosphere at ordinary temperatures; (2) that if helium once existed in appreciable quantities in the earth's atmosphere it must have escaped when the earth was far hotter than at present; (3) that hydrogen, on the other hand, might escape to an appreciable extent from the earth's atmosphere even at ordinary temperatures.

Luminous Rings in Lines of Magnetic Force.

A paper on the "Production in Purified Gases of Luminous Rings in Rotation about Lines of Magnetic Force," was read by Mr. C. E. S. Phillips, who described the apparatus used as consisting of an approximately spherical glass bulb, the ends of which were left open for the purpose of inserting two soft iron electrodes, half an inch in diameter, through air-tight flanges which themselves were cemented to the glass. The bulb was about 2½in. in diameter, and the electrodes were chosen of a sufficient length to enable them, while almost meeting at the centre of the bulb, to project outwards slightly beyond the rims of the flanges. A side tube was attached for the purpose of connecting the apparatus to a Sprengel air-pump and McLeod vacuum gauge. Two powerful electro-magnets were then adjusted, so as to strongly magnetise the electrodes when necessary. A low pressure having been produced in the bulb by the action of the air-pump, leading wires were attached to the iron electrodes to enable the discharge from the secondary of an induction coil to be passed through the rarefied gas. Under these conditions the effects produced in the usual glow-discharges by the magnetisation of the electrodes could be conveniently examined. It was seen that at a pressure represented by ·003mm. of mercury, and with the discharge just able to pass in the bulb (the magnets meanwhile remaining unexcited), on shutting off the current from the induction coil and completing the magnet circuit, a luminous ring appeared within the bulb in a plane at right angles to the lines of force and in rotation about the magnetic axis. The number of such rings could be varied by special devices, and their brightness largely depended upon the electrostatic condition of the outer surface of the glass bulb. The effect also depended upon the manner of stimulation of the rarefied gas within the bulb, and the shape of the magnetic field was of importance.—Prof. J. J. Thomson, F.R.S., stated that he had found the motion of positively-charged ions to be much smaller than that of negatively-charged ones—a fact which would account for the apparent preponderance of the negatively-charged ions in the tube.

Bacterial Treatment of Sewage.

Extracts from a report on the "Bacterial Treatment of Raw Sewage in Coke Beds" were read by Prof. Clowes—a method first experimentally carried out by the London County Council for treating the effluent from sewage dosed with "chemicals." Now coke of the size of walnuts is used, and beds from 4ft. to 13ft. deep have been tried. One treatment on the coke bed removes all the fæcal matter and 50 per cent. of the dissolved organic matter, whilst a second treatment removes a further 20 per cent. of the dissolved organic matter. The mode of procedure is to leave the sewage in contact with the coke for three hours, and then allow the coke to stand empty for seven hours for aëration. The effluent supports the life of fish, and neither it nor the coke becomes foul, although no bacterial improvement is brought about by the treatment—a factor that is advantageous for the final stages of purification. The efficiency of the filters falls off in time owing to clogging with the cellulose fibres derived from wood pavements, straw, &c., but much of this can be removed by a preliminary sedimentation and disposed of in a destructor. Fresh coke requires five or six weeks to get into working order; in dry weather, when the sewage is less dilute, the working is less satisfactory. Mr. W. Scott-Moncrieff followed with remarks on "The Place of Nitrates in the Biolysis of Sewage." He said there were three methods of recovering the nitrogen from sewage, the disposal of sewage directly on the land, the chemical precipitation of the sewage in the form of sludge, and the method described by Prof. Clowes. The bulk and dilution were the obstacles in the first method, whilst the second was not satisfactory. The third, however, properly conducted, was good; in fact, as the late Sir Edward Frankland remarked, it was a fermentative process like brewing, and, as the author said, the method of nature herself artificially aided. Sewage was a complex mixture, therefore different organisms had to work to break up the combinations. Hence the desirability of letting the process go on in stages.—Prof. Warington remarked that the process described by Prof. Clowes was really neither anaërobic nor aërobic, but partook of both characters. It seemed to him that neither had full play.—Mr. Dibdin pointed out that the bacterial treatment was a success, and could, by making a suitable bed, be made to yield an absolutely pure effluent, which was not always necessary. The important feature of Prof. Clowes's communication was the successful treatment of the sludge, which in London amounted to 40,000 tons a week, and cost a considerable sum to take out to sea. He remarked that the sewage of Leeds had been successfully treated on the coke-beds, although it contained a large proportion of chemical refuse.—Mr. Douglas Archibald doubted whether the bacterial treatment of sewage would be as efficient as the chemical treatment in destroying dangerous organisms.

Turbine Steam-Engines.

The Hon. C. Parsons, in referring to this subject, said that with turbine engines no lubricant whatever enters the steam part, so that the boilers become much less charged with oil than is the case with ordinary engines, and express water-tube boilers of the smaller tube type may be maintained in satisfactory working conditions for long periods; and, further, it is understood that the Board of Trade will be prepared to so modify their system of periodic inspection as to permit of such boilers being used for regular cross-Channel service. But perhaps the most important considerations are the increased comfort to passengers, owing to the absence of vibration and a remarkable smoothness of motion analogous to that of a sailing vessel, also the greater depth at which the propellers are placed below the surface of the water, reducing the liability to racing of the engines, which enables the speed of the ship to be maintained in heavy weather in a way that is totally impossible in the case of ordinary screw or paddle-vessels. If a service of 30-knot vessels were placed on the Newhaven and Dieppe line, it would become the fastest route from London to Paris; also, if the system were properly carried out as suggested, the time on the Dover and Calais route between London and Paris would be shortened by about half an hour. The draught of water with turbine engines does not necessarily exceed that of paddle-wheel vessels, and, as turbine engines are more readily and quickly manipulated than ordinary engines, and each side of the propelling machinery can be put ahead or astern independently, the manœuvring power is practically equal to that of paddle-wheel propelled vessels. The particulars of the proposed 30-knot turbine boats are as follows:—Length, 275ft.; beam, 30ft.; depth (moulded), 13ft. 1in. to main deck, 21ft. to awning deck; draught, 9ft. 3in. (about); displacement, 1,000 tons (about); speed, 30 knots; I.H.P., 18,000.

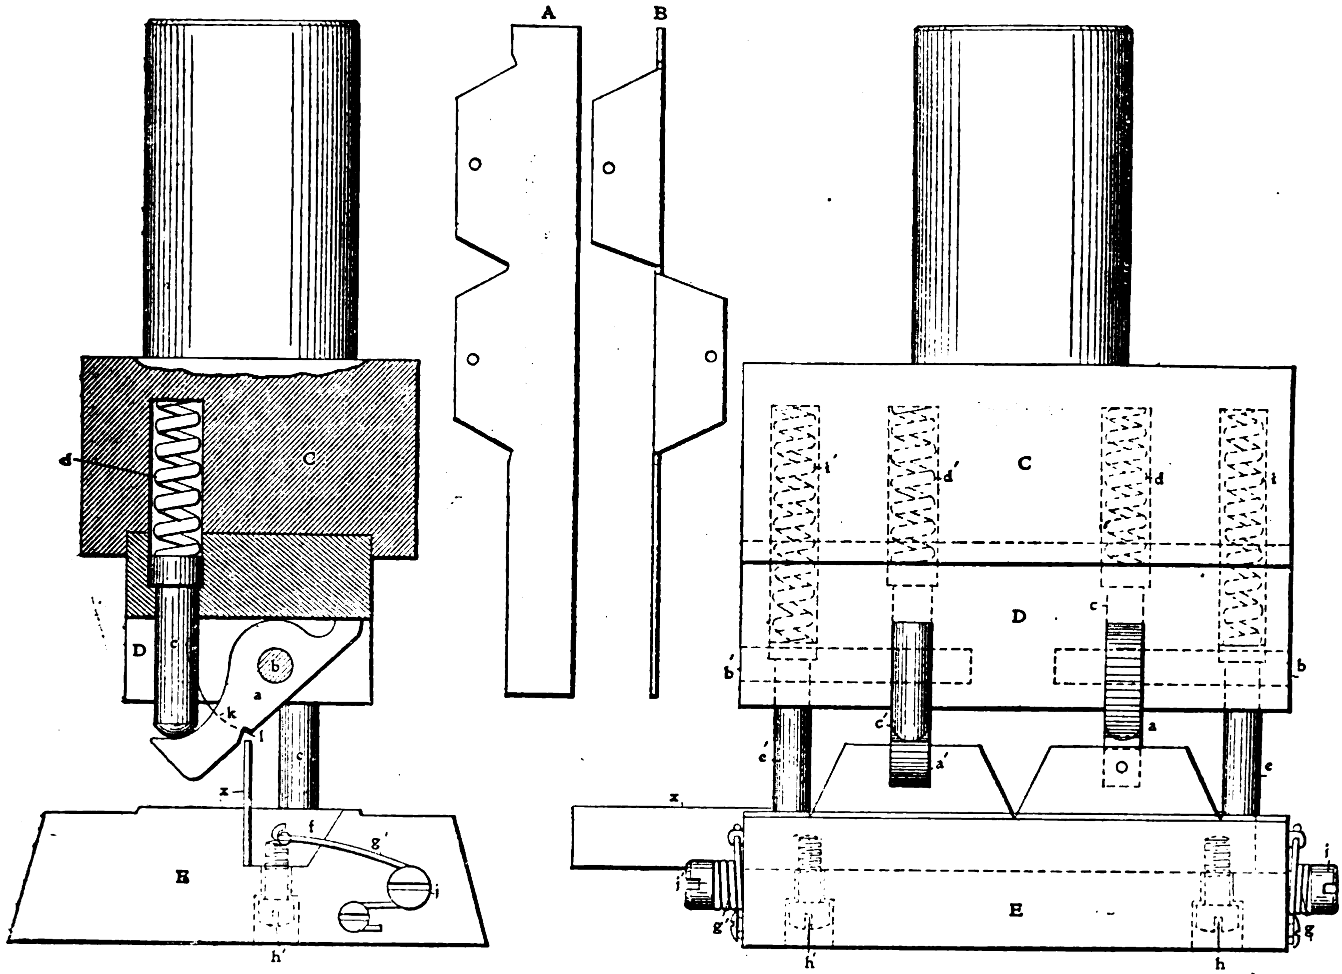
Vitality of Seeds.

It is well known that the vitality of seeds is not affected by low temperatures, but Sir W. Thiselton-Dyer described certain experiments that he had made in conjunction with Prof. Dewar to ascertain the influence of the temperature of liquid hydrogen on the germinating power of seeds. The result of the experiments went to show that life persists at a temperature so low that ordinary chemical action is practically stopped. Ordinary commercial samples of the seeds of barley, vegetable marrow, mustard, and pea were used. They were actually immersed in liquid hydrogen for more than six hours. The lowest temperature to which they were subjected was many degrees below the temperature of melting ice. The seeds, after being so immersed, showed no change visible to the naked eye. They came out of the ordeal as fresh and bright as they were before, and all germinated after they were planted.

Electro-motors on Board Ship.

A paper on "Electrical Machinery on Board Ship," by Mr. A. Siemens, was read, in which the author stated that direct driving was now generally preferred, and expressed an opinion that the type of generating plant now in use on board ship had reached a stage of development which would be improved, but not materially altered. To prevent the magnetic field of the dynamos affecting ships' compasses, "iron-clad" dynamos and double wires—one for the return current—were used. These conductors formed the most valuable part of the system of electrical installation for power purposes on a man-of-war. The superiority of the electric motor over small steam-engines or hydraulic distribution of power was dwelt on by the author. The two latter systems necessitated a network of piping all over the ship, which was difficult to arrange neatly, and gave endless trouble through leakage. The reason that the use of electric motors had not been more extended on board ship was due to the variation of the load that accompanied the working of most auxiliary machinery. In the case of the winch, for instance, it frequently happened that the strain on the cable increased sufficiently to stop the movement of the winch. This would cause the current through the electric motor to rise to an extent that might seriously injure the machine. It was impossible to overcome this by a fuse, as the interruption of the current would allow the strain to be taken off the winch, whereas in most nautical operations it was necessary to keep the strain on. To overcome this difficulty, shunt-wound motors might be used. These could be kept running continuously, the drums of the winches being operated through friction clutches, or special cut-outs could be applied in connection with series-wound motors. Through these cut-outs the current through the motors was not interrupted altogether, a by-pass taking a safe current. Examples of working a steering gear and rudder indicator were given. The suggestion that the main engines of a ship should be electrical motors was rejected as impracticable whether accumulators or steam driving, on the Heilmann principle, were adopted. A 6,000-ton ship propelled by 8,000I.H.P. would take 150 hours to cross the Atlantic, and that would be equal to 1,200,000H.P. hours. Fairly efficient accumulators gave ten watt hours per lb., so that a horse-power hour could be obtained for 75lb. of accumulators. The ship would therefore need 40,000 tons of accumulators.

More than half of the coke imported into California during 1898 came from Great Britain, while the remainder had its origin in Belgium, British Columbia, and Australia. The total amounted to 41,630 tons, which was an increase of 37 per cent. on the entries of 1887.



AN AUTOMATIC BENDING DIE.*

IT is very rare that we come across anything really new; so, although the combination here shown was new to me and to those around me, I do not claim that it will be new to all.

We have here shown a punch and die for bending the blank shown at A into the shape shown at B, making a "duck's-foot," such as is used in spacing the ventilating openings in armatures. In Fig. 1 is shown an end view (partly sectional) of the dies part way on the down stroke of the press, and with the "starters" just about to take hold of the blank. They consist of the tool-steel die E and punch D, which is screwed and dowelled from above (not shown) to the cast-iron holder C. The die E has a groove milled through it lengthwise, with one side perpendicular and the other side at an angle, as shown; to this is fitted the wedge f, leaving room at the perpendicular side for the blank x to be held tightly. Into the wedge f are driven the small pins to which the ends of the springs g' g are fastened, and then wound in turn round the screws $j j$, and the other ends secured by the small button-head screws as shown. The tendency of these springs should be to lift the wedge up, and away from the blank, thus releasing it after bending, and permitting a new one to be inserted. The motion of the wedge is limited by the screws h' h, which fit loosely in the die E, but are screwed home in the wedge.

The blank is slid along between the wedge and die until it reaches a stop, not shown, which locates it in its proper position; as the press comes down, the buffers e e' press the wedge down into the die, and against the blank, thus securely holding it. The buffers should be long enough to do this before the starters a a' take hold; also, the buffer-springs i i' should be quite stiff. Referring to Fig. 1:—The starter a is pivoted on the pin b, which is on the opposite side of the centre line from which the bend is to be made.

The little arm at the upper end serves as a stop to bring the notch, shown at l, directly over the edge of the blank, and the projection at the lower end has a cam on its upper side upon which the plunger c works, actuated by the slight spring d, thus returning and retaining the starter in position shown after each stroke of the press. The top edge of the blank, catching in the notch of the starter during the down stroke, is carried over by it in the direction of the dotted line K, until it reaches the face of the punch D, which it then follows till the final bump flattens it out at right-angles with the part held in the die E. As the two "feet" of the blank are to be bent in opposite directions, the two starters, a and a', must work in opposite directions, the pins b' b and the plungers c' c must be on opposite sides of the centre line. All parts of this punch are hardened, and the starters have to work very very freely on the pins b' b and in the slots of the punch D, so that there will be no binding when under pressure. I made this die to bend the above blank in one operation, which before had always been handled twice in two sets of dies. It was very successful, bending thousands, to my knowledge, and I believe it still to be in active operation.

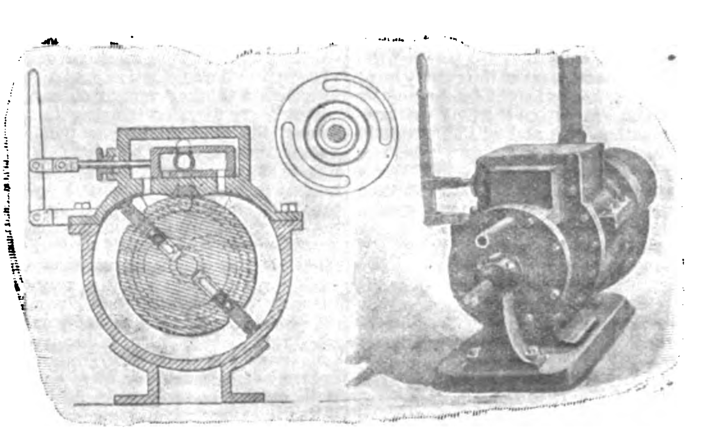
AN IMPROVEMENT IN ROTARY ENGINES.

THE accompanying engravings represent a perspective view and cross-section of a rotary engine, together with a cut-off valve employed therein. The inventors are James T. Hay and Gilbert L. Depuy, of Garland, Texas. The engine comprises a cylinder with a fixed abutment in its upper portion. The piston is mounted concentrically within the cylinder, and in contact with the abutment. In the piston two piston-heads slide, having blocks mounted to rock on their outer ends, so as to accommodate themselves to the shape of the abutment. The piston-heads are pressed into contact with the cylinder by springs, resting on trunnion-bars, engaging cam grooves in the head of the cylinder. Above the cylinder is a steam-chest connected with the cylinder by ports on opposite sides of the abutment. In the steam-chest a sliding reversing-valve, controlled by a lever, is mounted.



The valve is provided with ports adapted to register with the cylinder-ports, only one port of the valve being in register with the corresponding cylinder at a time. The registering-ports serve as exhaust-ports; while the cut-off port serves as a steam-inlet. One side of the slide-valve opens at all times into an exhaust-pipe, so that the exhausted steam can readily escape. Into the steam-chest a channel opens, registering at intervals with the segmental slots of a rotary cut-off valve secured to the main shaft, and revolving in a casing of its own. The valve controls the opening of a steam-supply pipe directly opposite the steam-chest channel. When a piston-head reaches a lowermost position,

the steam is cut off, the corresponding slot in the cut-off valve being out of register with the steam-pipe. As the other piston-head passes the abutment and steam-inlet, the other slot in the cut-off valve begins to register with the steam-supply pipe, and a second impulse is given to the piston. In order to prevent leakage of steam, the inner faces of the cylinder-heads, the interior of the cut-off valve-casing, and the cut-off valve, are formed with grooves adapted to receive the water of condensation. As the grooves fill with water, they form a packing for preventing the escape of steam.—*Scientific American.*

A NEW ACETYLENE GAS GENERATOR.

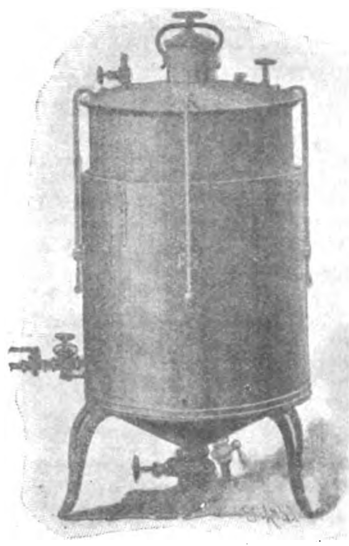
WE present herewith illustrations of a new acetylene gas generator, in which the production of gas is automatically regulated in accordance with the amount consumed by checking the water fed to the calcium carbide.

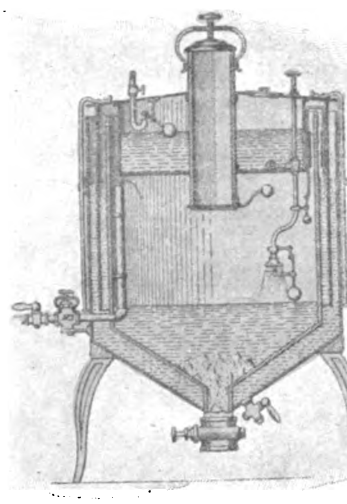
The apparatus comprises a generator surrounded by a jacket of water, a holder, the body portion of which occupies the space between the jacket and generator, a tank secured to the holder, and a carbide-receiver, which extends centrally through the holder and tank, and which is provided with a cover and with a weighted drop bottom. Into the tank extends a water-supply pipe, which is controlled by a float-valve. A water-distributing pipe runs downwardly from the tank, and is provided with a sprinkler which plays over the carbide, and which is provided with a float-valve. The water-distributing pipe is provided with two valves. Of these valves, one is controlled by a stem projecting above the holder, and is closed only when the machine is not in operation; the other valve is controlled by a weighted arm, and opened and closed by the rise and fall of the holder.

In operation, calcium carbide is fed through the receiver, and water is turned on at the supply-pipe so as to fill the tank to the height determined by the float-valve. The water from the tank will pass through the distributing-pipe and will be sprinkled over the carbide, thus generating gas, which is conveyed to the burners by a service-pipe. When the pressure of gas becomes excessive, the weighted arm controlling the valve in the distributing-pipe closes the valve under the action of the rising holder, and thus checks the water. When the pressure falls, the valve reopens automatically.

When the apparatus is to be cleaned, the lime is removed by opening a valve in the bottom of the generator. Water is then turned on at the supply-pipe, and is automatically shut off by the float-valve of the sprinkler when the desired level has been reached. After a time the water is drawn off. The operation is repeated until the generator is clean.

Further information regarding this apparatus can be obtained from Frank Zunino, 230, Washington-street, New York City.—*Scientific American.*





VOLTA AND THE ELECTRIC CURRENT.

THE Monday evening discourse before the British Association was delivered by Prof. J. A. Fleming, F.R.S., who took for his subject the "Centenary of the Electric Current." Copies of the lecture had been forwarded to Prof. Blaserna, as president of the congress of electricians assembled at Como, for presentation to the King and Queen of Italy. Telegraphic messages passed between Dover and Como, using the wireless telegraphy to cross the Channel, and also between the president of the British Association and Dr. Brouardel, President of the French Association assembled at Boulogne, the distance from the Connaught Hall, Dover, to Winnereux, near Boulogne, being 30 miles. In his discourse, Prof. Fleming said that the investigations of Alessandro Volta, born at Como in 1745, opened a new chapter in the history of electrical discovery by giving to the world the voltaic pile. To regard the modern uses of the electric current thus given to us by Volta was to realise the astounding results which a century had brought about. Some idea of those results might be found in the fact that in the year 1898 very little less than £85,000,000 was invested in Great Britain alone in electrical enterprise. Prof. Fleming having summarised Volta's researches, spoke of the wonderful researches of Hertz, which showed us that where alternating currents of very high frequency were set up in an open circuit the energy might be conveyed entirely away from the circuit into the surrounding space in the form of electric waves. At a certain intensity of strain the air insulation broke down, and the air became a conductor. This quality of passing quite suddenly from a non-conductive to a conductive state under the action of a critical electric pressure was a very peculiar and important characteristic of gaseous substances. It had been known for 20 years that tubes full of powdered metals were very curiously sensitive to electric sparks. The non-conducting mass at every spark became a conductor, but could be brought back to its original condition by a tap. Signor Marconi discovered that a long vertical wire attached to the sensitive powder-tube had the property of increasing enormously the distance at which it could feel the effect of the electric spark. These principles had received their most logical extension and completion in the evolution of the electro-magnetic wave telegraphy, developed by Signor Marconi on such a large scale within the last few years. The chief principle which underlay this industrial application of research was that the sensitive powder tube, when passing into the conductive condition, could be made to complete another voltaic circuit, and so operate any ordinary form of telegraphic instrument. Of course, the moment it was possible to close the voltaic battery, by merely making an electric spark at a distant place, innumerable applications immediately suggested themselves, one of the latest being the steering of self-moving torpedoes. Turning to the transference of electrical energy by wave motion, Prof. Fleming said that Hertz had proved that electrical energy could leave a rod in which a very rapid oscillatory current was set up and could travel with the speed of light outwards in all directions. Where was it after it had left the radiator and before it had arrived at the receiver? The answer was that it existed as free radiant or wave energy in the ether. Both optical and electrical phenomena had compelled the assumption of an imponderable material which could be the vehicle for energy in certain forms. After referring to Clerk Maxwell's researches, Prof. Fleming concluded by observing that from the starting point of Volta's discoveries a century's development had brought us to this point—that the actions we call an electric current, if alternated rapidly enough in direction, would end by producing a ray of light. We were, however, as yet in the region of conjecture, when we attempted to formulate a specification of the exact nature of the motional and configurational changes which must be at the root of observed effects. To devise a theory of the ether, such that from the simplest possible assumptions could be deduced the facts of electricity, magnetism, and optics, might be said to be the aim of physical inquiry at the present time.

SCIENTIFIC NEWS.

ON the proposition of Lord Lister, F.R.S., seconded by Sir A. Geikie, F.R.S., Sir William Turner, F.R.S., was unanimously appointed President-elect for the next meeting of the British Association for the Advancement of Science, which will be held in Bradford, commencing on Wednesday, Sept. 5. Lord Lister, in making the proposition, said that Sir William Turner was perhaps the foremost human anatomist in the British Islands, and was also a great anthropologist. On his shoulders had largely rested for many years the task of guiding the great medical school at Edinburgh, and he also occupied a most honourable position as President of the General Medical Council. Sir William, also, had long taken an active part in the work of the Association, and he was in all ways a man eminently deserving of the great honour of the Presidency of the British Association. Sir J. Evans proposed that there should be asked to serve as vice-presidents, The Earl of Scarborough (Lord-Lieutenant of the West Riding), the Duke of Devonshire, the Marquis of Ripon, the Bishop of Ripon, Lord Masham, the Mayor of Bradford, the Hon. H. E. Butler, Sir A. Binnie, Prof. Rücker, and Prof. Thorpe. The last meeting of the British Association during the nineteenth century will therefore be held in Bradford in 1900. Glasgow is the place of meeting for 1901.

An important discussion took place during the meeting of the British Association in connection with a paper by Prof. Clarke, of Washington, D.C., on a "Proposed International Committee on Atomic Weights," which Prof. Tilden, who read it, followed by a paper of his own, expressing the opinion that the only chance of obtaining uniformity was to submit the subject to discussion at the British Association, the Chemical Society, and foreign scientific societies, and finally to the international meeting of chemists which it is proposed to hold in Paris next year.

In a communication to the Paris Academy of Sciences by Prof. James Dewar, it is stated that a tube containing liquid hydrogen surrounded by another vacuum tube containing liquid hydrogen shows the gas as a solid, the upper surface being a solid froth. The lowest temperature is stated to be about minus 259° C. For a full comprehension of these remarkable experiments the papers must be consulted; but if there is any knowledge in the grave Faraday, Andrews, and others must be pleased at the results which their successors have attained.

The International Geographical Conference (the seventh) will be commenced on Sept. 27 at at Berlin, and will continue until Oct. 4. A large attendance is expected, and the following papers, amongst others, are already announced:—"The German Deep Sea Expedition," by Dr. Chun; "The Results of an Expedition in East Greenland," by Prince Albert of Monaco; "The Geographical Distribution of the Tea Plant," by Mr. John M'Ewan; "The Plains of Ancient America, especially Mexico," by Mrs. Zelia; "The Oceanographical Results of the *Fram* Expedition," by Dr. Nansen; "The Antarctic Expedition," by Sir Clements Markham; "The German South Polar Expedition," by Dr. Erich von Drygalski; "The Distribution of Deep Sea Deposits," by Sir John Murray; "The Geographical Cycle," by Prof. W. M. Davis; "Some Particulars of the First and Second Cataracts of the Nile," by Dr. de Claparede; "Discoveries in England in Remote Ages," by Prof. Sieglin; "International Ballooning," by Prof. Hergesell; "Scientific Ballooning by the German Balloon Society," by Prof. Assmann; "A Project for a North Polar Expedition," by Mr. Arthur C. Jackson.

Dr. R. H. Traquair, F.R.S., will deliver a course of free lectures (12) at the Museum of Practical Geology, Jermyn-street, S.W., on the Pleistocene Mammalia, commencing on Monday Oct. 2 (5 p m.), and continuing on the following Wednesdays and Fridays.

The Harveian Oration will this year be delivered by Dr. G. Vivian Poore before the Royal College of Physicians on Wednesday, Oct. 18.

The Friday evening lecture at the meeting of the British Association was delivered by Prof. Charles Richet, whose subject was "La Vibration Nerveuse," that is, the rate of transmission of nerve impulses, which he said could not be

repeated more than ten or twelve times a second. Prof. Richet states that if one tried to think of a set of words in succession he could never pass that speed, and could not receive a more rapid succession of sensations on the same organ. This period, then, might be called the psychological "unit of time." If the rapidity were greater, sound, electricity, and light would be perceived as independent undulations, not continuous sensations; were it slower, one would see the motion of the hour hand of a watch and the growth of a tree.

M. Scheurer-Kestner, whose untimely death is announced from Paris, was born at Mulhouse in 1833. His name has been prominently before the world of late years in connection with the "affaire," and his death is "untimely" in the fact that he could not have known of the pardon. M. Scheurer was a distinguished chemist (on the commercial side), and was one of the most brilliant pupils of Prof. Wurtz. Marrying Mlle. Kestner, he added her name to his own, and embarking in various industrial enterprises which his knowledge of chemistry enabled him to carry on at great profit, he early in life made a fortune, and, entering the political world, became one of the vice-presidents of the Senate of France.

The death is announced of Karl Störk, of Vienna, in his 67th year. He was well known as a laryngoscopist and a writer on medical subjects; but, in addition, he was the inventor of many useful instruments and mechanical accessories.

At the meeting of the British Association Mr. A. L. Rotch, of the Blue Hill Observatory, Massachusetts, stated that the first crossing of the English Channel in a balloon was accomplished by an American, Dr. Jeffries, and M. Blanchard, a professional French aëronaut, in 1785.

A preliminary report on the erosion of the coasts of the United Kingdom was presented to the British Association by Mr. Whitaker, F.R.S., which shows that systematic observations have been made in a tentative way, and that replies to a circular sent out by the council of the Association to coastguard stations had been received from over 400 stations.

At the conclusion of Sir A. Geikie's address in Geology at the British Association meeting, M. Gosselet, the president of the Geological Society of France, in proposing a vote of thanks, said that the hearts of all geologists went out to Sir Archibald Geikie for the great services he had rendered to geological science. Geologists were especially indebted to England for the excellent mapping of the geology of the British Isles, which splendid work served as a model to all other countries. Lord Lister, in seconding the vote, said the president's address was at once worthy of that meeting, of their French and Belgian visitors, of science, and of Sir Archibald Geikie himself. Though Sir Archibald did not quite agree with Lord Kelvin's position, he had nevertheless paid a warm tribute of gratitude to physicists, and admitted that Lord Kelvin had done very valuable work in bringing the subject of the age of the earth within more definite limits.

The *Athenæum* says:—We learn that the Russian Government propose to adopt the Gregorian Calendar at the beginning of next century —i.e., on January 1, 1901. According to this, they will still make next year a leap year in accordance with the old Julian reckoning, but will afterwards fall into line with other Christian nations by making their dates correspond with what they would have been had the Gregorian rule of dropping a leap year at the end of each century (except each fourth century) been observed since A.D. 325. Let us hope that before another century is completed the more simple and accurate rule will be substituted of dropping a leap year at the end of each period of 128 years without exception, so that the next dropped after 1900 will be 2028.

Wireless telegraphy formed an important attraction to the visitors to the meeting of the British Association, and, as it happened, they had the advantage of hearing or seeing that it could do very well even in a thunderstorm. Some preliminary tests were made before the meeting by Prof. Fleming, and the "show" tests for the benefit of the members of the Association were satisfactory.

Meantime some interesting experiments with wireless telephony have been carried out by Sir W. H. Preece, F.R.S., and it remains to be seen whether they will not be more useful than those made with wireless telegraphy. At present there is no doubt that the latter is, or can be made, a very serviceable servant for many purposes. The distances over which it can be used are in the experimental stage.

The proposed Antarctic expeditions formed a prominent subject in the Geographical section at the meeting of the British Association; but nothing more than has been previously discussed was brought forward. Admiral Makaroff, however, in describing his voyage in the *Yermak*, said that explorers should no longer be deterred by the ice, but should compel the ice to bend to their will. His ice-breaker made splendid practice on the ice in the Polar regions last August; but it is considered that she ought to be slightly improved as regards strength. It would seem from the failure to reach the mouths of the Siberian rivers this year that an "ice-breaker" must always pilot the cargo vessels.

The *Oceanic*, the largest steamer in the world, has made a most successful voyage to New York, and now it is reported that Cramps, of Philadelphia, have prepared a design for a steamer for the American line, which is to be 710ft. long, and which, if constructed, will be the longest vessel in the world. The average speed of the *Oceanic* is reported to have been over 19½ knots, but bad weather was met with on some days.

The ice-breaker for Lake Baikal has been re-erected and successfully launched into the lake. The dimensions are 290ft. by 50ft., and the draught of water under ordinary working conditions is 18ft. 6in. The vessel is of 4,200 tons displacement. The principle of watertight subdivision has been carried very far, so that the vessel must be pierced in several compartments before she is in danger of sinking, and, in addition to the usual watertight bulkheads, an inner bottom is fitted on somewhat the same system as that which obtains in ships of war. The cars are run over a hinged gangway on to the railway deck, where they are securely fixed in position by means of special appliances. There are three sets of triple-expansion engines, working at a pressure of 160lb. Two sets drive twin propellers, fitted, as usual, at the stern, and the third a propeller at the bow of the vessel. The last is for the purpose of disturbing the water under the ice, so as to assist the heavy steel stem to break up the solid field ice, that it may be pushed aside by the advancing vessel. This is the first occasion on which so large a vessel has been built, shipped on an ocean-going steamer, transferred to railway waggons, and finally re-erected.

News has reached Rome from the Polar expedition which is being "personally conducted" by the Duke of the Abruzzi. The duke and Captain Cagni made accurate observations, which enabled them to fix the geographical position of Cape Flora at ten miles further east than its position on the charts. When the provisions had been disembarked the *Stella Polare* pushed northwards on July 26, and attempted to pass through the "British Strait," but found the ice too thick. Then an attempt was made to round Alexandra Land, but without success, on account of the enormous masses of ice. A second effort was made to penetrate the "British Strait," and by dint of breaking the fresh ice with the prow of the vessel, and by steaming slowly through the narrow channels of open water between the icebergs the *Stella Polare* managed to pass into the open sea. There she met the whaler *Capella*, with the Wellman expedition on board. The *Capella* brought final letters and news of the expedition up to August 6, when the two vessels parted company. The temperature at that date was about 32° Fahr., and as the sea was still fairly open, it is expected that the Duke of the Abruzzi and his companions will be able to winter at 81° of north latitude, or even further north if a sufficiently sheltered spot can be found.

It would be interesting to learn how much of truth there is in the following paragraph from a London morning paper: "When the Princess of Wales is back in England she intends to interest doctors in the curative virtues of electric light. Her Royal Highness, with the King of Greece and several of the Russian princes now in Denmark, paid a visit some days ago to Prof. Finsen's electric-light institute in Copenhagen for the cure of disease, and spent some time in witnessing the effects of the treatment on lupus. This method has given such striking results in lupus, that in a few years there will be no patient suffering from the disease in all Denmark."

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

CLOUD PHOTOGRAPHY—JOSHUA AND THE SUN STANDING STILL—THE CHALDEAN DAY (?)—LEGAL REMEDY—LIQUID AIR—ASTRONOMICAL SIGNS—AN OPTICAL IMPOSSIBILITY—MUMMY WHEAT—THE ETHER—THE ORBIT OF POLARIS AND ITS APPROACH TO THE EARTH—METEOROLOGY AND WEATHER PREDICTION—DEATH BY LIGHTNING—MASS OF MERCURY.

[42838.]—As mentioned in your "Scientific News," on p. 86, *Knowledge* for September contains a remarkable series of photographs of clouds, taken by MM. E. M. Antionadi, F.R.A.S., and G. Mathieu, accompanied by a paper descriptive of the method by which these most valuable pictures were obtained. Personally, I have studied this work with great interest, inasmuch as my own efforts (and accidental results) at cloud photography have been by no means a conspicuous success; the actinic activity of the blue sky seriously interfering with the contrast between it and the clouds, which is so apparent visually. The authors of the paper before me surmount this difficulty by the use of coloured screens before the lens of the camera; such screens being of a yellow or yellowish tint, produced either by (*a*) actually yellow glass, (*b*) yellow gelatine, or (*c*) a solution of bichromate of potash contained in a cell with rigorously parallel sides. The contrast is intensified by use of isochromatic plates. They have even succeeded in photographing a rainbow. The value of their results is incontestable alike to the meteorologist and the physicist. M. Léon Teisserenc de Bort, at his private observatory at Trappes, has already succeeded in measuring the height of clouds above the earth's surface by it. He employs two photographic theodolites of the type adopted by our own Government in India, separated by a distance of 4,324ft. (say, 0 82 mile). They are united by a telephone, so that any given conspicuous cloud may thus be simultaneously photographed. In this way, as I have just said, the height of clouds above the earth's surface have been measured with great accuracy. I need say no more, but would refer everyone interested in the subject to the paper itself.

If "Wilmay" (letter 42797, p. 92) will refer back to Vols. XXXVI. and XXXVII. of the ENGLISH MECHANIC, he will find the question of the standing still of the sun and moon thoroughly threshed out in a most numerous series of letters and replies. I may perhaps quote from one of my own communications on the subject in the former volume, in which, speaking of its interpretation, I said, "Jahn among the Roman Catholics and the late Dean Milman among English Churchmen: the former regarding it as a sublime poetical trope, and the latter speaking of it, *totidem verbis*, as 'pure poetry.'" As a statement of physical fact, it is precisely on a par with the occurrences alleged to have taken place in Psalm cxiv. 3 and 4.

"Silverplume" (letter 42799, p. 92) really does Mr. Hardy too much honour by noticing his wild nonsense about the Chaldean day at all. The earth rotates on her axis in 24 hours, and "the evening and the morning" are, and always were, one (as we read they were the "first") day. I should be curious to know in what work or works Mr. H. found the remarkable statements on which he founds his calculations.

It seems to me that letter 42806, p. 93, is written throughout on the assumption that an action must, *ex necessitate*, be brought in the High Court of Justice; but I would remind "Hear Both Sides" that the defrauded purchaser has his remedy, if he chooses to seek it, in the County-court, a certainly less costly mode of proceeding.

Does "G. A. H." (letter 42809, p. 94) believe in perpetual motion? Or did he ever hear of the Irish sailor whose blanket covered his feet but did not quite come up to his chest, and who cut a piece off the bottom of it and sewed it on the top?

The symbols for the Zodiacal signs now in use, as also those employed for the planets (concerning which Mr. Lambert puts query 96600 on p. 98), had their origin with the Mediæval astrologers and alchemists. But ☉ and ☽ for the sun and moon date from the Egyptians.

There is some remarkable mistake in query 96601 on p. 98. It is utterly impossible for any one at or near the sea-level to see hills 60 or 70 miles distant.

Mr. Dormer (query 96607, p. 98) may take it that De Candolle's pronouncement as to the allegation concerning the alleged germination of mummy wheat is strictly correct.

"Curious" (query 96609, p. 98) will find a great deal that will well repay perusal in that admirable little book "Light, Visible and Invisible," by Silvanus Thompson, published by Macmillans.

The announcement which you reproduce in the fourth paragraph of your "Scientific News," on p. 113, is, as it stands, not too intelligible; but it has since been supplemented by a more detailed account, whence it would appear that what Prof. Campbell really has observed by the familiar spectroscopic method is a variable approach of Polaris to our Solar System with a velocity of eight kilomètres (4·97 miles) per second. In two days this will increase to fourteen kilomètres (8·7 miles), and in the next two days again decrease to eight kilomètres. Hence α Ursæ Minoris must be revolving round a dark and invisible body, or rather the two must be revolving round their common centre of gravity in an orbit about the size of that of our own moon, once in four days. From measures made at the Lick Observatory in 1896, the rate of approach of the Pole-star to the earth was calculated to be twenty kilomètres (12·42 miles) per second, and this Prof. Campbell attributes to the presence of a second dark body, and further believes that Polaris itself and its primary, or attendant, are approaching the earth at the rate of eleven and a half kilomètres (7·15 miles) per second. All this must be only provisionally accepted; but the skill of the well-known observer at Lick must render any results at which he may have arrived worthy of consideration.

"M. E. V." (letter 42812, p. 114) does well in calling attention to the curiously local character of the weather. No one would ever listen for an instant to the sunspot-and-weather humbugs, or to the so-called astro-meteorologists, were it not that this enables them to point to *some* spot on the habitable globe at, or in, which a particular prediction of theirs has been more or less verified.

May not the explanation of the difficulty felt by "F. C. B." (query 96662, p. 121) be found in the fact that the electrical discharge passed through the warm fluid blood in both cases, and not through the hides of the cattle or the clothes of the man?

In reply to "Garsdale" (query 96669, p. 122), the most recent determination of the mass of Mercury would make it about 1-21st that of the Earth.

A Fellow of the Royal Astronomical Society.

CRATER NEAR LIMOCHARIS.

[42839.]—IN Elger's book on the moon I observe that he shows a small crater pretty close to Limocharis on the N.W., and he also in the text describes it as being in that position. On, however, examining the same region, as shown on some photographic lantern slides ("Lick Obs.") I do not find any small crater on the N.W. of Limocharis, but just such a one as Elger describes, W., or rather south of W., in a position where Elger shows no crater. Is it an error of Elger's to show a crater to the N.W., or are there two craters, and has the more southerly one been omitted? I shall be much obliged if "F.R.A.S." or anyone else will inform me. **R. P.**

THE TRIPLE SYSTEM OF POLARIS—CAPELLA—STAR MAGNITUDES.

[42840.]—IN the issue of the ENGLISH MECHANIC for this week (Sept. 15) I notice a paragraph announcing that Prof. Campbell has made a dis-discovery regarding Polaris. It says (p. 113): "Simultaneously, they revolve together around a third body, as the stars and moon revolve around the sun." Should this read: "As the earth and moon revolve around the sun," or "As the planets and moon revolve around the sun"?

Again, it says: "This is the most interesting discovery, surpassing even that of Capella." As I only took up Astronomy a short time ago, I do not know what this discovery regarding Capella is. Can any reader of the "E. M." inform me, or tell me where I can obtain the information?

To "F.R.A.S.," or any other reader of the "E. M." who can tell me: What is the greatest magnitude star I shall be able to see with my telescope, a refractor of 2·85in. clear aperture, with powers of 60 to 240? Also, can you give me examples (names or numbers of stars) from the first magnitude down to the faintest I shall be able to see?

Earlsfield, S.W. **Silverplume.**

RIGEL.

[42841.]—WITH reference to letter No. 42752, p. 64, I find on looking through my notebooks extending over the last 25 years, and using a fine 5in. Wray refractor and a 10·5 Calver reflector, that whenever I have noted the colour of Rigel I have always put it down as having distinctly a *yellow* tint—even in the clear skies of Malta and Crete. In my opinion, there is no comparison between Rigel and Vega. Vega must come first, inferior to none, not even to Sirius, in its intense electric colour.

I think that each of the giant stars has a beauty and colouring peculiarly its own, and I never see any one of them exactly like any other.

"*Yellow-white*" is just about a fair description of the colour of β Orionis.

T. H. Foulkes, M.A.,
Chaplain to H.M. Forces.

British Camp, Kandia, Crete, Sept. 7.

TELESCOPES: TO E. P. CLARK.

[42842.]—THE information solicited by your correspondent in 42784 is, so far as his lenses are concerned, very easily supplied, provided he finds the lenses properly made and properly mounted. If not correct already in these respects, no useful information could be given without knowing accurately the refractive and dispersive powers of all the three lenses, a matter not easily ascertained by an amateur devoid of suitable apparatus and some skill in using it. Mr. Clark is correct in supposing his telescope to be one of Mr. Rogers's construction—generally now known as the "dialyte." If, as very possibly is the case, the three lenses are properly made and properly placed in respect to each other, or, in the latter circumstance, even approximately so, the adjustments necessary for perfect vision need not be very difficult. I fear, however, he has placed the "corrector" lenses with their flatter sides the wrong way. As usually computed, the two flat sides require to be *outwards*, the convex part of the corrector being next the object-glass, the concave flint lens behind it. But as the arrangement, however, admits of considerable variety, and as I know nothing about the glass of his lenses, I should not be held to fix the above relative positions definitely.

This device, which was considered a very hopeful one before optical flint-glass became cheapened (or even possible in large discs), is not now much used, although some excellent dialyte telescopes by Plössl, of Vienna, are to be found in some of the Continental observatories.

The colour correction admits of easy and perfect adjustment; but except for the very centre of the field of view the correction for spherical aberration requires, besides shift of relative position, a rather delicate proportioning of the curves. I computed a case lately, but am not content with the marginal correction it is likely to give. A Mr. Ingall, of London, is, I believe, quite an authority on these telescopes, and he would, I am sure, be glad to give your correspondent every assistance in his power. With a rigid and well-made tube and good fittings the dialyte can be made to give very good results; but although Mr. Ingall has done well, it is a telescope still worse (although cheaper) than the ordinary achromatic for an amateur to make successfully. It would be well also for your correspondent to consult Mr. Rogers's original paper on the instrument in the "Mem. Ast. Soc. of London," Vol. III. p. 229, 1828. This can be seen in a public library.

Next, concerning Mr. Clark's queries about his old Gregorians, the replies may be given somewhat as follows;—First, in cleaning the tarnished metallic specula, I prefer dilute ammonia to long wiping with alcohol, although I generally finish with the latter. The ammonia solution I find most suitable may be made by adding 5 minims of strong *liquor ammoniæ*, such as photographers use, to 1oz of pure water—preferably distilled. Moisten with this solution a piece of cotton-wool, or clean, soft cotton well washed (preferably an old and much-worn piece), and daub it gently all over the surface of the speculum, or if very bad staining seems to require a little friction, any rubbing done must be very gentle, and must be *uniform over the entire surface*, whether it needs it or not. *No local friction* must be used. If not badly stained, only very gentle wiping is required; but in all cases it is best to allow the surface to remain wet with the solution for a few minutes, not more than five, or if a very bad case, say ten. Prolonged action of the ammonia tends to make the surface crystalline—this must be avoided. Finally, wash well, and apply a little absolute alcohol in the same manner, wiping the surface dry while the spirit evaporates; *do not permit it to dry spontaneously*, and *do not use "methylated spirits"*; also, in no case use saliva, or even breath, on the metal, as the breath contains volatile fatty acids, which tend to tarnish metal.

Secondly, regarding the adjustment of the specula, it may almost be assumed that the large speculum requires no shifting of its supports, which, indeed, seldom permit of any such adjustment. Remove the eyepiece, and look at the small speculum through the hole in the large one, keeping the eye some distance behind it, so that the circular obstruction of the small speculum seems centrally situated in the bright hole, the telescope meanwhile being pointed to a part of the sky near the horizon. Keeping the eye in this axial position, see whether the bright circle of a size a little less than the small speculum be placed concentrically with it. If the bright circle (which is an image of the large speculum) appears to lie off to one side of the small speculum, screw *inwards* that one of the three bearing screws at the back of the small speculum which seems the *nearest* one to where the bright circle has become eccentric—repeat the process until bright circle and dark rim become concentric.

In the centre of the above bright circle will be seen a small dark circle, which is an image of the hole in the large speculum. If all be right, this circular spot ought to have a narrow annulus of equal width all round it, which is an image of the small speculum itself; but if this narrow annulus be eccentric, either the large speculum is out of square with the tube, or the small speculum is out of the tube axis. The latter adjustment can easily be made with inside calipers, if necessary, but the former requires some filing of the large speculum supports, which should not be necessary if correctly made at first.

These directions seem rather complicated to read, but a few minutes' practice of them will soon enable your correspondent to adjust his specula.

ERRATUM.—In letter 42816, on Reducing Light, middle column, p. 115, line 20 from foot, omit "to."

H.

TELESCOPES, ETC.

[42843.]—MANY thanks to Mr. Ellison for his kind notice of my letter (No. 42622). I am sure that if he will give a detailed description of how to build his stand, many readers besides myself will be grateful. I expect an 8½ reflector, altazimuth mounting by Linscott, to arrive before long, and shall certainly make attempt at mounting it equatorially on Mr. Ellison's plan.

"What has the Equator to do with it?" Don't "speak disrespectfully of the Equator," please. *Experto crede*, he can make his power felt. The heat in this place during about nine months of the year is like that of a well-warmed greenhouse, and makes manual labour very exhausting. Again, I have to send hundreds of miles for the simplest tools. However, I shall have a try. There are compensations out here: a horizon clear in all directions, and magnificent definition night after night for many months in the year.

According to Chambers, Vol. II. p. 285 (4th edition), Dawes used a stop of perforated cardboard for bright objects, but it is not stated whether he did so in observing the sun.

I see that my complaint against the telescope vendor has attracted some attention. Mr. Caplatzi is not the dealer in question; nor would anyone, I fancy, suppose that he was. I do not in the least doubt his statements. There are trustworthy dealers, no doubt, and there are dishonourable buyers. He accepts my principle that instruments should be examined by a third party, and I suggested no detailed plan. Mr. Ellison's letter shows that one gentleman, at any rate, is willing to give his services. Friendly co-operation among the readers of "Ours" will do much.

Mr. C. is mistaken if he supposes that I object to a fair price for a fair article. I do not; nor do I imagine that the difference between buying and selling prices represents clear profit. I do not accuse the shoptician whom I have criticised of dishonesty; but I think I have fair grounds of complaint when, after I have paid him his own price for an instrument, I am bothered with a finder that will not find, screws that screw badly, and eyepieces that have to be changed. I think I may fairly charge the individual in question with stupidity, carelessness, and blindness to his own interests as well as to mine. **Pauper et Exul.**

GREGORIANS—γ¹ ANDROMEDÆ AND "H."

[42844.]—"ELL HAY" distinctly tells us now that "as to testing (his) small speculum, (he does) not pretend to ability to do so." Now, to those fully acquainted with optical work, is it not a well-known fact that the testing of a mirror is a much *easier* process than the making of the same? Indeed, have we not been regaled in "Ours" with lengthy instructions for *testing* by some whose actual work could only pretend, as we know, to a very subordinate place? In view, however, of this relative difficulty in these branches of art, we find immediately on the back of above avowal of inability, the apparently irreconcilable statement, "I have nowhere acknowledged want of either theoretical

training or practical experience in telescope-making." In reply, one might point to the numerous obtuse questions and out-of-place remarks made on the Gregorian by your correspondent, all of which, while quite in keeping with the expressions of one inquiring into things he knows little or nothing about, are strangely at variance with those of an expert in the art, either from the aspect of "theoretical training or practical experience": to claim the possession of these qualifications now, most surely tends to cast either a doubt of sincerity of purpose over the whole tenor of his letters, or to cause us to suppose that his own appraisement may be at fault while his sincerity is intact. In either case, letter 42783 does not improve matters, unless we are to suppose that the whole question of Newtonian alteration into a Gregorian, with the "discoveries" made during the process, was meant for a joke;—if so, while regretting I took so much trouble to supply the information asked, I agree to take it as such.

Unfortunately for the "joke" theory, his remarks about the Gregorian eyepiece in 42579 do not tally with his reintroduction of the same in 42783, in which he now says, "To ask the opinion of others about an eyepiece is not to profess ignorance." In the first place, "Ell Hay" *has never yet asked* the opinions of *any one* of us on said eyepiece; in the second place, we find him saying (in 42579), "Progress in the alteration is checked, because I have found it involves getting new eyepieces." Now, does anyone, at least one so well instructed as your correspondent, use the present perfect part of the English verb ("I have found") when he means other than that the event is but recent—in fact, when the words "I have just found" would be equally suitable? Note the *simultaneous* "discovery" *re* the stand.

It would appear that he questions very much my remarks about a given injury to the figure of a speculum being more injurious to the final reflected image, in his case ten times (leaving out the eyepiece action), when that speculum is used as a Gregorian, than when used as a Newtonian. One would have thought the "theoretical training" mentioned would have made it evident that the elongation of focus by the small speculum, and the increase of primary divergence from supposed error, are on the same scale.

As to "Ell Hay's" objection to my use of the phrase "he knows" in connection with my inability to act upon his invitation to inspect his work, the desire to preserve my incognito fully explains.

"Expense" is again commented upon in 42783—we all know that scientists as well as others try to shirk it, but no one expects to have the question of "expense" brought in, while deciding comparative merits from a purely scientific point of view, which, indeed, was the only aspect in which I attempted to consider the comparative merits of Newtonians and Gregorians.

The "mere theorist" assertions of the writer of 42783, in trying to belittle the opinions of the famous authorities I gave in 42757, as favouring direct-vision telescopes, have probably been already sufficiently met in (42814).

Again, we are asked to accept the notion that "the common judgment of astronomers (is) in favour of the Newtonian form," which, in view of what I quoted from some of the foremost astronomers seems a strange statement to make. In one respect, perhaps, "Ell Hay" is right, however, for with recent *amateur* astronomers, saving the mark (telescopists would seem a more appropriate word in the vast majority of such cases), and these amateurs of *our own country* almost entirely, the Newtonian has had its innings for a few years, the reasons for which I thought I gave, but with astronomers of the true kidney "Ell Hay" must know this is not the case in any marked degree; for, on the contrary, whatever reflectors have been added to large public observatories of late years, either in this country or America, have nearly all had perforated specula for use as Cassegrainians or Gregorians, although, as already stated by me in 42757, *very large reflectors*, in which the requirements as to distinctness are not severe, these giants being mainly needed for such purposes as the observation of nebulæ and comets, or for spectrum work, will probably, for a time at least, be possible only as Newtonians. Indeed, I began this series of letters with a statement of this very fact concerning concerning "observatory" reflectors, when I said in 40968 speaking of compound reflectors: "On a scale of no mean dimensions, they have been recently constructed for the use of some of our foremost amateur and professional astronomers."

Respecting the γ^2 Andromedæ controversy, as to whether one, two, or no green discs at all, are visible when this star is resolved, I shall again ask him to bear in mind that as my letter of Feb. 17 merely introduced the size of a hypothetical green disc *to compute from*, and made no mention whatever of one or more green discs being *at all visible*, and as I could scarcely be led to conceive that anyone could possibly take that ridiculously nonsensical meaning out of my words, I was at no trouble to periphrase, in order to prevent that absurdity. Even after an attempt of mine to re-explain the whole affair in 42757 (which see), I find "Ell Hay" saying in 42783 that my explanation of the matter is "neither ingenious nor ingenuous,"—a remark in which *I quite agree with him*, for, as a simple and uncontroverted scientific fact, the above two adjectives are both equally and totally inapplicable to it. But if "Ell Hay" be found differing so markedly from what I thought was the only possible conception, it is for me pleasant to find our most competent and obliging contributor, my elder brother "F.R.A.S.," remarking in 42065, on this very letter with which "Ell Hay" finds such fault, and saying, "(he) knows most thoroughly what he is writing about," and this certificate, which I prize not a little, surely outweighs the remarks of the man who has had the aforesaid "theoretical training and practical experience."

Then we find the writer of 42783 saying γ^2 Andromedæ "*is not sea-green*," and that, in consequence of this, my computations founded on that colour are all wrong. Might I refer him to "Webb" who calls the companion we are discussing "sea-green" as plainly as he can; while others, Smyth for example, use the term "emerald-green." We all know how largely provisional and conventional colour names are, especially the names of the compound or hyphenated colours; but let your negatory critic consult a colour scale in a mineralogical treatise, say Dana's, and he will find "emerald-green" at the blue end of the green scale and "pistachio-green" at its yellow end. It is also common knowledge that the most prized form of emerald, also sometimes called the beryl, is in lapidaries' terms known as "*aquamarine*," a name which so well informed a man as your correspondent must know to mean simply "sea-water," so that those writers who use the term emerald-green for the colour of γ^2 Andromedæ, only differ in mere phrase from those who use the words "sea-green."

But as a matter of fact, the above colour name never once occurred to me when looking up my spectrum map for the particular λ to be used in computing the hypothetical disc, of the colour of the spectrum place mean between those of the two components. I took the place by measurement, and only afterwards affixed the colour name to popularise the information regarding the spectrum place employed, being pleased, however, when I found that colour agreed with the *observed* one as given by "Webb," &c. I never trust my own estimation of colour, as several of your readers already know. Finally, let it be understood I criticise only statements, *never the writers of them*, and in this case I must thank "Ell Hay" for his flattering references to me in the opening and closing paragraphs of 42783. H.

REDUCING LIGHT OF TELESCOPE.

[42845.]—None of the plans suggested is really the best. What is wanted is a plan which causes no interference with definition—nearly all these suggestions do. In the case of the sun we don't want to absorb the heat, which most of the plans mean, but to throw it away. In the plans where coloured glasses, fluid-cell, &c., are suggested, there is the evil effect on definition through these surfaces not being perfect planes nor perfectly parallel to each other. The one and only correct plan is a first-surface reflecting prism of about 16°—a diagonal. The plane surface of it must, of course, be perfect. The parallelism of the back and front surfaces is of no consequence. Here there is no interference of any kind, and the light and heat are passed out into the air, and not into the eye-tubes or eyepiece. It is good for either refractor or reflector, and reduces the light and heat more and better than any other plan.

With the Newtonian the means for reducing light and heat are the best of all, and a larger aperture can be used than with any other instrument, for an unsilvered plane can be used instead of the silvered one. Again, an unsilvered mirror can be used, thus reducing light and heat to almost nothing, and this without interference of any kind—either colour, refraction, or distortion. I have tried perforated screens, but did not like them at all.

I have made several telescopes with the above provisions to get rid of light and heat, and with double-concave mirrors. One was a 30in. mirror. Thus most of the heat and light passed out at the low end of tube—about 2½ per cent. only sent to the plane, which reduces it again, and then again at the prism, so that little reaches the eyepiece.

G. Calver.

REDUCING THE INTENSITY OF LIGHT—MICRATOMIC ETHER.

[42846.]—In view of some of "H.'s" remarks (letter 42816), I should like to offer a few of my own, especially with reference to my previous letter (42729) on this subject (in which, by the way, occurs an obvious misprint in the punctuation). Having read of the experiences of others with perforated screens, I determined to make a trial myself. When I turned my telescope on the sun, there was, unfortunately, no spot visible, so I was compelled to focus on the limb. This was not easy, as, of course, the latter was "boiling"; still, try how I would, the limb always appeared surrounded with several concentric rings of light. As this is not the case when the plain aperture is used, I naturally concluded that a perforated screen did not improve the definition.

I did not, however, in my letter proceed to "confidently condemn their use," but confined myself to stating my experience and asking for an explanation. I may add that the optical parts of my refractor are by the late Andrew Ross, and, needless to say, are of a high degree of excellence.

With regard to the second heading of this letter, Mr. Howse (letter 42825) seems to have the haziest notions as to what I actually did say in my previous letter (42787) on this subject. It happens so often, when abstruse questions of this nature are discussed, that scientific terms with very definite meanings are freely used with other than their proper senses, and the discussion degenerates into mere logomachy.

The "complete explanation" which the crude hypothesis of "micratomic ether" is supposed to afford of the cause of gravitation is, I am afraid, only likely to raise a smile. I must confess I cannot understand what Mr. Howse means when he says "Let me ask him ("J. M. W.") what properties water has in common with a mixture of oxygen and hydrogen which it does not share with other elements and compounds." Will he kindly explain?

Light is certainly one of the forms of radiant energy, in which the latter becomes manifest to us through the medium of our senses. (How light is demonstrated to be energy by means of the photometer is a mystery.) It is, however, transmitted to us neither through a void nor through the agency of matter, but through the ether which pervades the visible universe.

Will Mr. Howse kindly explain what bearing his remarks on the nature of magnetism and electricity have on the question?

If he supposes magnetism itself to be a form of energy he is certainly mistaken. Magnetism is probably due to a stress set up in the ether; energy is consumed in creating the stress, and that energy can be recovered when the system returns to its original configuration. It would be almost as incorrect to say that the force which a compressed spring can exert was also a form of energy.

I can discover nothing in my previous letter which could possibly be construed into the extraordinary statement:—"He ('J. M. W.') tries to point out that it is against the laws of nature for an element to combine with itself . . . ." What I did say was that it seemed unlikely that we should ever succeed in splitting up the elements into anything still more elementary.

In the hands of Mr. Howse the hypothesis of micratomic ether seems to be nothing more than an allotropic form of the "Protyle Theory." It would be futile to enter into the merits and demerits of this latter hypothesis in this paper.

We are unfortunately left in ignorance as to the wonderful way "Lucretian's" hypothesis is going to explain the periodic law. When we are more enlightened on this point, it will then be time to offer criticism.

Does Mr. Howse seriously think that the difference between native gold from Australia and California is either "atomic or molecular"? If so, a course of elementary chemistry would be beneficial. While Australian gold contains about 99 per cent. gold, and a mere trace of silver, that from California contains about 90 per cent. gold and 10 per cent silver. Specimens of pure gold prepared from any source whatever are all absolutely identical.

Trin. Coll. Oxon. J. M. W.

OVERHEATING OF GAS-ENGINE.

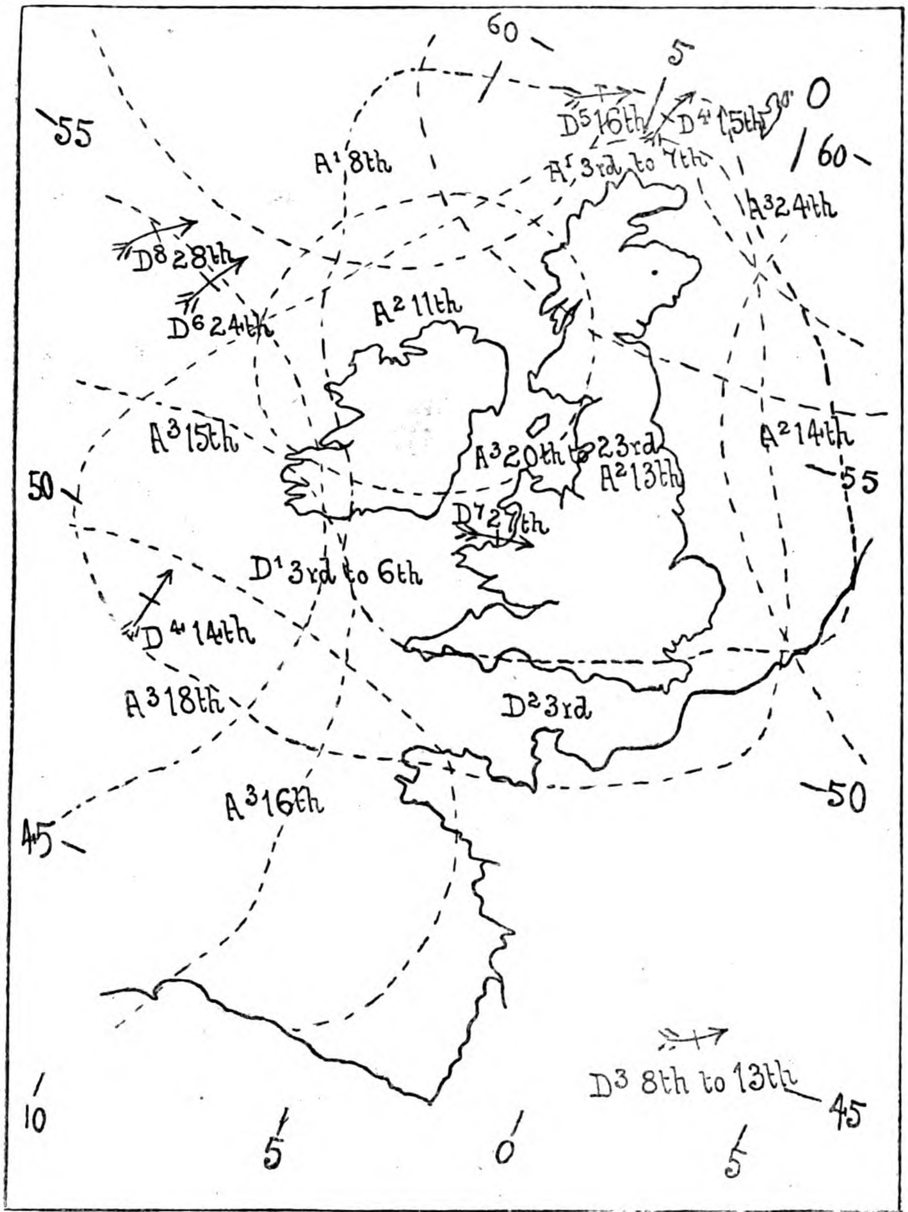
[42847.]—Having had trouble with a 2H.P. gas-engine from the above cause, I tried a number of experiments to see if I could remedy same. After several trials I attached a bend to length of pipe (same size as circulating to the end of the return pipe where it enters the tank). This piece extending to a depth of 12in. in the water, acting, to my idea, like a siphon. This altered matters greatly, as I can now run the engine for a stretch of six hours, and the jacket barely getting warm. Before altering a two-hours run almost carbonised the oil, and sometimes engine slowing down considerably, and missing fire. I write this in the hope of any contributor experiencing the same difficulty giving it a trial, when I am sure they would be well repaid for the trouble taken.

Enfield. Sebberger.

STEREOSCOPES.

[42848.]—If "R. S. D." (letter 42836) wants to see stereoscopic views without a stereoscope, he had better get "Impressions of America," by the Rev. T. C. Porter, where he will find a long explanation, taking up four pages, with three diagrams. I would gladly send a *résumé*, if not a full account.

C. E. R. Brocklebank.



THE WEATHER OF THE BRITISH ISLES IN AUGUST—THE LATE PROLONGED DROUGHT—TEMPERATURE.

[42849.]—THE following tabulated statement shows, as usual, the weather changes over the British Isles, with "effect" in relation to "cause."

Date.	Cause.	Effect.
August 1 to 6	High pressure to N.; shallow depressions to the South-westward.	Hot weather; fair as a whole, but close air; local thunderstorms.
to 14	Arctic anti-cyclone, giving place to Atlantic high-pressure system. Low pressure over the Iberian peninsula.	Fine and warm, with easterly breezes.
15 & 16	Depression to Northward; high pressure to South.	Squalls from westward in the South, with fine weather; rain and thunder in the North.
17 to 23	Atlantic anti-cyclone covering our islands; low pressure to East and South.	Generally fine, warm weather. Very fine and hot in the South and East.
24	Low pressure to W.; "straight isobars" throughout.	Hazy in the North, rainy in the West.
25 & 26	Anti-cyclonic conditions.	Fair throughout.
27 to 31	Low pressure on N.W., spreading inwards over the whole of our islands.	Unsettled and showery generally; break in the drought.

For explanation of the chart, readers are referred to page 492 of the last volume.

It may be interesting to note that August completes the *fourth* consecutive month with a rainfall *below* the average, and the *second* with a rainfall of *less than half* the average in the South-east of England.

The actual figures for East Surrey are:—

Month.	Average Rainfall.	Actual Rainfall, 1899.
	in.	in.
May ..	2·01	1·35
June ..	2·02	1·02
July ..	2·47	·61
Aug. ..	2·37	·32
	Aver. total 8·87	Actual total 3·30

8·87in.
3·30in.

Total deficit in four months 5·57in.

The temperature, on the contrary, has been *above* the average throughout the entire period of eight months—January to August—the figures being:—

Month.	Average Temperature.	Actual Mean Temperature in 1899.
Jan.	38°·5	43°·0
Feb.	39·5	44·5
Mar.	41·7	45·5
April	47·2	48·5
May	53·1	54·0
June	59·4	62·0
July	62·4	67·5
Aug.	61·6	68·6

Meteor.

THE DELUGE.

[42850.]—IN your issue of Aug. 25, Mr. E. L. Garbett, in letter 42720, quotes Rev. S. G. Wilson, M.A., as saying: "In 1883 the *Levant Herald* published a detailed account of an alleged discovery of the Ark on Mount Ararat. . . It would be interesting to know what it is that has apparently deceived these worthy . . . chroniclers."

The bare facts of the case are as follows:—There is, and was in 1883, a morning daily paper published at Auckland, New Zealand, called the *New Zealand Herald.* Every Saturday there was a special column or so contributed by a writer signing himself "Calamo Currente." In 1883 (or perhaps 1884) April 1 fell on a Saturday (or possibly Sunday). On that Saturday "Calamo Currente," instead of his usual running criticism of the topics of the week, filled his column with what purported to be an extract from the *Levant Herald*, giving a detailed account of the discovery of the Ark on Mount Ararat.

This "extract" from the *Levant Herald* was copied into nearly every newspaper in England and America, and even found its way into Continental papers. Six months or so later "Calamo Currente," much surprised at and somewhat apologetic for the extent to which his April-fool joke had spread, explained that he had invented the "detailed account of the discovery of the Ark on Mount Ararat," and that the *Levant Herald* (so far as he knew) had no existence outside of his imagination.

I was in Auckland at the time, and write from recollection; but Mr. Garbett can verify the details by referring to the files of the *New Zealand Herald.*

A. J. Bliss.

THE COMET AND THE DELUGE.

[42851.]—MANY of your readers ere this must have been weary of the above heading. Mr. Garbett calls Lyell and Darwin "supreme asses"! but is unable to foresee that this stigma can be very appropriately adapted to himself. The former he terms "Breakneck Lyell," with inane mockery of the circumstance of his lamented death. These scientists arrived incontestably at their conclusions from a study of palpable facts, and yet Mr. E. L. Garbett denounces their writings as "absurd." He can accept and revel in the belief of the Mosaical legend, in accordance with the scope of his own limited understanding.

This legend was written by men of crass ignorance, under the then prevalent idea of a flat earth, vaulted over, or covered by a firmanent. All this will not bear the test of the slightest scientific investigation, which informs us that the earth could never have been flooded so as to involve the annihilation of all living things. If more than five hundred skilled maritime shipwrights had been occupied for many years with the impossible task of collecting all the scant supply of timber available in the locality, they could not have built a vessel sufficiently large to contain and accommodate the living animals therein to be reserved for the continuance of their kind, together with an army of men that would be required to collect their food and attend to their needs. A floor space of more than eight acres would be inadequate for this purpose, with a structure strong enough to withstand the furious currents and hurricanes consequent upon such a world of rushing water. For such reasons the Ark with its conditions is a mere fable, and could not have been a reality.

Immense quantities of submarine shells and fossils are to be found in many localities on the tops of mountains, proving that these were upheavals from the bottom of the ocean, and not the result of a forty days' apocryphal flood. These self-evident relics must have been a puzzle to the ignorant men of the period, and may have given rise to the legend of a universal Deluge.

F. H. Wenham.

[42852.]—I HAVE to thank Mr. Garbett for the valuable information which he gives me concerning the progress of cometary astronomy. I did not know it before. Probably more was known about comets 5,000 years ago than now.

Possibly ink was one of the fluids which overwhelmed the earth at the time of the Deluge. It seems to be now connected with it. I hope "Nouri" will give us some more information about the Ark. Perhaps what he took for the signature of Ham will, on closer inspection, be found to be surmounted with a shamrock, with the name "Matterson, Limerick" below.

W. H. S. Monck.

A CHEAP ANEMOMETER.

[42853.]—THERE are doubtless many readers of the "E. M." who take a great interest in meteorology, and would like to possess a full set of recording instruments, but are, like myself, deterred by the expense. Many thousand amateur observers have to content themselves with the thermometer, barometer, and the rain-gauge; but the study of the most interesting phenomenon of all—the wind, is

practically beyond their reach. Even at the stores the cheapest anemometer is listed at £3 5s.—a price prohibitive to all save the wealthy. Having long desired to possess one of these instruments, I have set to work and constructed a very satisfactory substitute for exactly eighteenpence! Of course, it has no claim to scientific accuracy, and cannot be compared to the standard instrument; but it is capable of affording the owner considerable information as to the rate of the wind from day to day. First of all construct a "windmill," such as can be seen in many country gardens to scare the birds away, mounted on a pivot, and provided with a vane to keep the "mill" always facing the wind. Mine is constructed wholly of wood, having four arms, about 18in. diameter, the arms being slightly twisted so as to insure the wheel always turning in the same direction. This is mounted by a wood screw into the end of a stick 18in. long by ⅝in. thick, a washer intervening. At the other end a fan-shaped piece of thin wood is fixed vertically to form the vane. The centre of gravity is then found, a hole bored at this spot, and the whole fixed by a long screw or nail to some elevated support so as to move freely with the wind. The recording part of the apparatus consists of one of those cheap (but good) American cyclometers, which is firmly fixed close to the revolving windmill. A small screw is fixed into one of the arms so that its head engages with the star-wheel of the cyclometer. A drop of oil on the pivots and the machine is ready for use. The cyclometer should be read at the same hour every day, say 9 a.m.; but, of course, it may be read at shorter intervals—in fact, the more often the better. The result, of course, is in miles, which can be reduced to revolutions by multiplying by the appropriate factor (732 for my particular instrument), but I do not consider that necessary. As an example, I may mention that for the 24 hours ending 9 a.m. this morning my instrument registered 172 miles; to-day, with a fresher wind, it has already got to 133 miles in only seven hours.

Reymond.

AHAZ'S DIAL.

[42854.]—THE return of the shadow on the sundial of Ahaz may, or may not, have been caused by a parhelia or mock suns, as Mr. Garbett explains (letter 42822), most likely not. It was most probably caused by a movement of the earth. Joshua's miracle of stopping the sun and moon was not the actual stopping of the sun and moon, but a movement of the earth, causing the sun and moon to remain in view longer than usual.

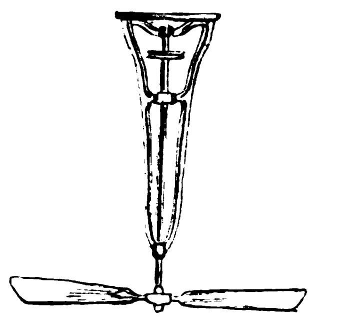
If this is so, let us consider would it not be possible to better our condition in relation to the sun? Why can't we go round the sun in the same manner that the moon goes round the earth? Let the land side be day, and the oceans night. In this condition war would be unnecessary—the same with money, and time would fall into disuse. There would be no more poverty. "Behold, the days come, saith the Lord, that the plowman shall overtake the reaper, and the treader of grapes him that soweth seed, and the mountains shall drop sweet wine, and all the hills shall melt."—Amos ix. 13.

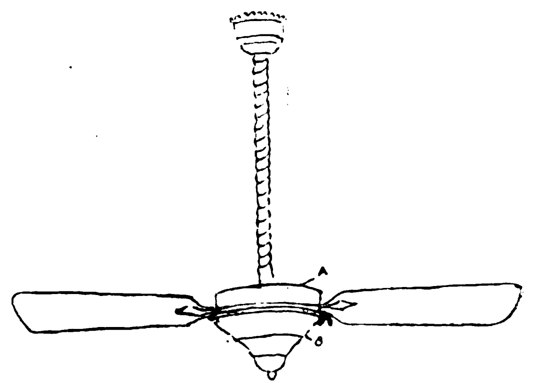
Little Bookham.

[42855.]—IT does not seem as if any of your correspondents are aware of what has been written about this matter a good many years ago, and it would be well, before filling your columns with what is at the best but irrelevant matter, that they should make themselves acquainted with the papers on the subject which appeared in *L'Astronomie*, Vol. V., for the year 1885. These papers consisted of (1) a communication by Flammarion, describing how, by means of a simple alteration of the inclination of the face of an ordinary dial, the shadow could be made to go backwards to the extent required. This could be done all the year round except at the two Equinoxes. So perfect is the method that Flammarion gives an engraving at the beginning of his paper of a dial he has had erected in the grounds of his observatory at Juvisy, to enable him to do this at pleasure. The face of the dial is first of all placed at the same inclination as the latitude of the place, and by means of a slotted quadrant at the sole and a pinching screw, that inclination can be altered 5° or 10°, or any other number required, the round rod which casts the shadow being placed exactly in the centre of the dial and perpendicular to its face.

The second paper (2) is a mathematical dissertation on the accuracy of the subject by Colonel Guillemin, of the Swiss army, who communicated the fact first to Flammarion. There seems to be no occasion for entering into a discussion as to whether or not the prophet knew that the shadow could be made to go back by natural means. Those who wish to enter into that question had better read Flammarion's paper, and a reply to it from the theological side given in a following number in the same volume by a French Catholic priest.

At a meeting of the Royal Scottish Society of Arts about four years ago, Mr. W. B. Blaikie, F.R.S.E., when exhibiting an improved astrolabe





constructed by him, which he termed "Cosmos," showed in my presence the retrogradation of the shadow upon that instrument by means of the light of a candle.

A few months ago "H." promised to give a description of the means used for ascertaining the truth of "flats." Perhaps he will now be so good as to fulfil that promise.

Procella.

[42856.]—AMONG the questions raised by Isaiah's miracle there is the connection between *ten* degrees and the *fifteen* years that Hezekiah's life was lengthened. We must remember the distance of each of the mock suns from the true sun is always 22½° of our measure. It depends on the refractive power of ice, and cannot vary. Forty of their degrees, therefore, went to a quadrant, and 80 to an average day of twelve hours. Now, Scripture defines the regular lifetime of Postdiluvians as 120 years. In Genesis vi. 3, we read that the Lord said, "My spirit shall not strive with man for ever. In their going astray they are flesh: yet shall his days be 120 years." Now, as "ten degrees" of Ahaz's dial was an eighth of an average day, so would 15 years be an eighth of 120.

Thus we see that Psalm xc. has no reference to average life. It was written by Moses (who himself lived to be 120) to deplore the shortness of his people's lives in the Wilderness. King David, who died at 70, was really only middle-aged (the middle between 21 and 120), and all who fail to reach 120 die prematurely. Jehoida the priest, in the reign of Joash, lived to be 130.—2 Chron. xxiv. 15. Anna the prophetess lived 91 years after her marriage.—Luke ii. 37.

E. L. Garbett.

ELECTRIC FANS IN AMERICA.

[42857.]—THOSE of your readers who have not visited the United States of America would hardly realise the extent to which electricity is being used in that country for ventilating and cooling purposes during the hot summer months, and it may be of interest to some of them to have a short description of the apparatus used for these purposes.

The fans of which I shall give a brief description are those used for keeping in motion the air in rooms, offices, &c., not so much for the purpose of ventilation as to create a cooling breeze, for in many offices and stores the heated state of the atmosphere makes some means of creating an artificial draught almost a necessity.

The first kind of fan used for this purpose consisted of a vertical shaft carried on brackets attached to the ceiling, and carrying on its lower end two or more wings, or blades, made of wood, and set at a slight angle, somewhat after the style of the sails of a wind engine, churning the air horizontally, and at the same time, owing to the set of the blades, giving it a downward motion. The driving power was communicated by means of a belt and pulleys from shafting. But as this necessitated the use of some engine or motor to run it, besides the use of shafting in places where it was often inconvenient and unsightly, it became evident that if a fan could be designed which would contain its own motor, and do away with shafting and belts, there would be a great demand.

About twelve or fifteen years ago the founder of a firm now engaged in turning out thousands of electric fans a year designed one of this class, consisting of an electric motor suspended from the ceiling, and carrying the blades on a shaft, very much after the fashion of the belt-driven fans, with this exception: that, instead of having a pulley on the top end of the shaft, it had an electric motor.

It will not be necessary to follow the development of this fan from its crude form to its present state; but a description of the fan as it is now made may be of interest, especially as the description will apply with some variation to many other makes of fans in use in America.

The motor consists of a ring armature, revolving outside the field-magnet cores, which are built up of laminated discs. The armature is carried vertically on a spider which carries the wooden blades, which have a sweep of about 5ft., and make about 150 revolutions per minute. The commutator is of a very peculiar construction, and consists of a fibre disc carrying 24 flat strips of brass, which are riveted on, leaving a space of about $\frac{1}{16}$in. between each. Copper brushes press against the flat surface presented by these bars or sections, and carry the current to the armature.

The armature and commutator run on a stationary vertical shaft, which is attached to a brass bracket carrying the field-magnets. This method of using a ring armature with internal fields allows a very low speed without sacrificing the efficiency of the motor, and also keeps the size of the motor within reasonable limits.

The whole is suspended from the ceiling by means of an iron pipe covered with ornamental polished brass or nickled casing, and the motor is hidden by brass or plated covers, A B, which allow a great variety of ornamentation and give a highly-finished appearance.

Instead of being suspended from the ceiling, these fans are sometimes mounted on columns or floor stands, and are much used for driving away flies and mosquitoes in restaurants and other places where these pests are apt to congregate, serving this useful purpose in addition to creating a cooling breeze.

Another kind of motor used on suspended fans, is that of the iron-clad type. In this a drum armature is used, and the casting forming the field magnetic circuit completely incloses the armature and commutator. This design makes a very compact and efficient motor, and is sometimes seen in this country applied to fans of the propeller class and small motors.

Perhaps the most common type of fan now used in America is that known as the propeller, consisting of a motor with a drum armature running horizontally, and carrying four or more blades at the end of the shafts.

All the better class of fans of this description are of the iron-clad design, and generally have carbon, instead of copper brushes.

The great objection to these fans is, that they create too much draught in front of them; but do not circulate the air round the room, while, on the other hand, the fans suspended from the ceiling keep up a steady circulation of the air, without creating unpleasant draught.

It is not probable that the demand for electric fans, for cooling purposes in this country, will ever approach that of America; but there are many places, as the late hot weather has forcibly reminded me, when their use would be an agreeable luxury, if not an absolute necessity, and the spread of facilities for obtaining current should cause electric fans to come into more general use here.

Space will not permit me to give more than the above brief outline of the application of electricity in this direction in America, or to touch upon the subject of its application to exhaust fans, for ventilating large buildings and factories; but the subject is an interesting one, and might well engage the attention of your readers, even in this country, where the extremes of heat are not so severely felt as they are across the Atlantic.

James O. G. Gibbons.

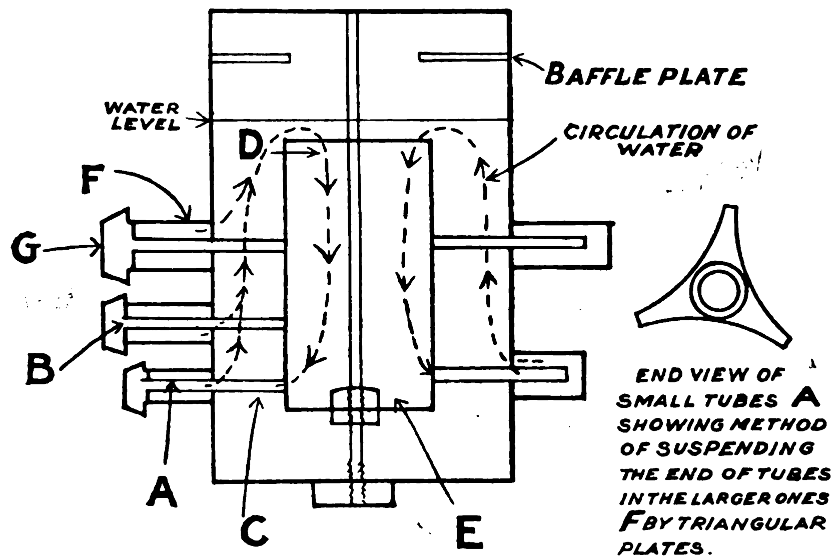
UP "DEVONIAN," G.W.R.

[42858.]—ON p. 64, "Scorpio" says that Warren made up six minutes on booked time in the 17 miles between Didcot and Reading, which does not correspond to the times I gave: Didcot Station being passed at 2h. 46m. 28s., and Reading at 3h. 7m. 0s., which gives the time between these two stations as 20m. 32s.—i.e., 32s. over the 20m. allowed. Again, the Reading to London journey took half a minute over booked time, which proves that Warren eased down after Didcot, being 3½ early at that place.

Ealing. O. R. Walkey.

STEAM-BOILER FOR MOTOR-CARS.

[42859.]—I THINK the neat design shown on page 90 (42792), Sept. 8, might be improved by the



following:—By having internal tubes, A (see sketch), to run into fire-tubes, F; the end B being, of course, open and supported in F, as shown in end view, by a triangular washer arrangement. The end C of the tube to be screwed into a cylinder, D, which is suspended, as shown, in boiler, and fastened in same at end E by two nuts, one each side of the stay. The end E of cylinder is perforated with holes, and end D is about 1in. below water-level of boiler. This arrangement, with small internal circulating tubes in larger ones, is adopted in one class of water-tube boiler with considerable success, it being found that the boilers will withstand considerable forcing. The circulation in this case would, of course, proceed from D through small tubes, A, into larger ones, F, and so up to the water-level and down again into D. These tubes F and A might, I think, with great advantage be bent down slightly at the free ends, which would help the steam as formed to escape to the steam space. The cylinder D cannot get short of water by water-level getting below the top of D because of the holes at E. The idea of the cylinder D is to keep the circulating currents separate, and so improve the circulation. In this case the boiler, if strongly made, should be able to withstand a lot of rough work, which the design (42792), though very neat, would not, the steam being formed in the tubes and driving the water out, and there, as the pressure varied, coming out with a rush, besides getting quickly burnt out if much forced. The feed-water should enter at lower end of D. The ends G of tubes F should have a screwed cap.

Ogap.

[42860.]—WILL Mr. Allison (42792) please say what length ⅜in. brass tubes are in sketch of motor-car boiler, and about what size should I have to make for an engine with a pair of cylinders 2in. bore, 4in. stroke? Also, would Mr. Allison give sketch and dimensions for an oil-burner for same, to burn benzoline or paraffin? Would a sheet-iron casing lined with asbestos do in place of fireclay cylinder?

J. Wells.

[42861.]—I AM only too glad to give friend "Water-Tube" (42830) any information in my power. In the first place, the boiler is vertical, which would be implied from the statement in my description to take steam from the top plates. The boiler should not be filled with water more than two-thirds up; otherwise it is very apt to prime, and it is very necessary that no oil should be put into the cylinder, as very nearly all the steam is condensed and used over and over again. Coal cannot be used in road locomotives, nor must any steam be visible. Coke or charcoal would do; but, standing, would blow off at a terrific rate, as all tubular boilers are wont to do, as they make steam so very rapidly. Oil-burners are not expensive. Write to Mr. Hicks, tool-merchant, of Chelmsford, who will supply you with a suitable one. Paraffin is only about 7d. per gallon. I may state that a boiler of the dimensions of the drawing supplies a cylinder of 2¼in. diam. with a stroke of 5in., good enough for any motor tricycle. I have made many such boilers in my time, and with the exception they prime somewhat if care is not taken, they answer admirably, and there is very little fear of their bursting. The only chance is that the bolt might possibly break, that being the weakest point; but, however, 100lb. would be the extreme wanted. You should, however, test up to 150lb. cold water. Any other information I can give I should only be too happy to.

R. Allison.

MOTOR CYCLES.

[42862.]—As the person responsible for the design of the Components Dion Motor as fitted to tricycles by the Ariel Cycle Company, the Swift Cycle Company, and others, referred to by your correspondent "Monty" in a recent issue, I desire to compliment him on the great grasp of the details of the motor and the tricycle, as shown by his able, and, on the whole, very fair letter. There are one or two points, however, in which he requires correction.

I do not think that the motor placed in front of the back axle was ever tried by some French makers years ago and given up, and I would be glad to be furnished by your correspondent with the facts on which he bases this assertion; nor can I admit his contention, "the reason being not far to see." All the reasons given by your correspondent are fallacious: the side bearings are not cut down in the least, but are all, without exception, longer and larger in diameter than any of the French motors hung on to the tricycle behind the main axle. This cutting down is far from being a disadvantage, because the side bearings being much closer together, the bending strain on the crank-shaft is much less. As regards an accident to the valve-rod foot, this can be taken out without disturbing anything at all, beyond unscrewing the valve-rod guide-bush out of the crank-case; this bush, I may explain, is larger in diameter than the valve-rod foot. Again, your correspondent is entirely mistaken in supposing that the valve-rod foot had anything to do with the stoppage of Mr. Stocks in his twenty-four hours' ride. The reason was an unseen flaw in the inlet-valve stem. Unfortunately, the rider had no spare parts with him.

I cannot admit that "A two-speed gear is necessary for anyone riding in hilly country," and I ask this question from your correspondent's letter to be read with this extract from the same: "People do not want to be summoned for furious driving every time they use machines." The motor under discussion geared six to one with the tricycle is capable, has, and does drive a tricycle up any hill the gradient of which does not exceed one in six (there are not many such to be found), and on the level will give a speed of about 22 miles an hour, and proportionately faster downhill. I admit that it seems well-nigh impossible to fit a two-speed gear to this motor; but in view of the foregoing incontestable facts, I have no desire so to do, and I would like to have your correspondent tell me, presuming for the moment that he will accept them as true and reliable, whether in his opinion and under such conditions the extra work and complication of a two-speed gear is worthy of consideration.

I agree with "Monty" that, theoretically, a clutch between the motor and the tricycle which would allow of the motor to run loose when tricycle is being ridden in traffic, is an advantage; *but* I do not see my way to design it, and even did I, would not recommend it: in all probability it would give considerable trouble.

I am pleased to note your correspondent is satisfied with the workmanship and general appearance of the motors and tricycles. I think that many cycle-makers are at the moment much too slow in seizing upon the opportunity they have of fitting reliable motors to tricycles of their own manufacture. Perhaps they will waken up soon. Your readers can accept my assurance that from my own knowledge every part of the motor and motor-cycles referred to were made in England with British capital and British labour. **Charles Sangster.**

Cycle Components Manfg. Co.,
Componentsville, Birmingham.

THE FUTURE OF AERIAL LOCOMOTION.

[42863.]—REPLYING to J. Sutcliffe, letter 42803, the reason that small birds, such as sparrows, tomtits, linnets, &c., beat the wings vigorously for a second or two preparatory to folding them close to the body, is, as before described, that, compared with the weight of the body, the wing area or supporting surface is small, thus necessitating their number of strokes to be beaten with greater frequency than those birds with ample wing area. The folding enables the wings to evade the air resistance, the weight of the body contributes to increasing acceleration, and the impetus gained impels the bird either horizontally or at any degree of obliquity upward or downward, the last greatly facilitated by the tail, the operation being repeated alternately as long as the flight continues. When, however, the bird desires to fly upward from the ground to a roof, it gives a vigorous leap upward; the body is inclined, and it strikes the air as a kite. The wings are inclined at the angle required by means of the universal joint at the shoulder (which enables the wings to incline themselves at any degree of obliquity). Furthermore, Dr. Pettigrew states his opinion that in each beat of the wing a current of air is drawn after it (which may be verified by experiment), and the results of such swift operations of the small wings necessitate the folding close to the body to avoid the air currents thus set up. It is for this reason that I have stated that it matters not whether the air is calm, gusty, or what; the bird, when once in the air, has the aërial currents entirely under control. If we take an ordinary common carrier-pigeon and hold it suspended upside-down in the hand, and suddenly let go, it will be found that it regains its equilibrium quicker than the eye can catch the return of its equipoise. Or, if we hurl it away from the body in a huddled heap, whilst you are watching it, it has regained its stability by a few vigorous flaps with its plastic wings, and appears to have merely flown aloft under ordinary circumstances. These experiments, with many other interesting ones, I have made with a pair of pet homing carrier-pigeons;—all of which tend to favour the opinion that with properly-made artificial wings and a thorough knowledge of bird mechanism, individual flight is really within human bounds to accomplish.

Now Mr. Challis will, I feel sure, pardon me for again correcting him on a few somewhat untenable opinions respecting my system. In the first place, in letter 42751, he ventures an opinion that a flying craft on my principle would only go with the wind or dead against it, and the wind would act on the rudder when "tacking" at cross angles against it, and blow it from its course. I assure Mr. Challis, in all friendly spirit, that this is a fallacy as absurd as it is irrational, which may be conclusively demonstrated thus: The bird in motion has two forces to propel it through the air, and not one, as he states—viz., gravitation. The downward pull of gravity is one certainly, yet equally positively is the great *propelling* force of the wings when beaten to be taken into consideration, and if he will only construct an artificial wing as explained in my previous letter (42704), he will find how true are these remarks. Thus, when cross-currents retard the velocity of the bird's progress, this enormous momentum residing within the bird, materially assisting gravitation, literally *forges* the bird through the atmosphere. Now, if a small bird gains stability aloft, it is within reason that a large apparatus much heavier in bulk and weight must of necessity retain its stability with increased momentum under these conditions.

I note with extreme surprise that Mr. Challis in his first letter discredits the paddle principle as a misconception, and in letter 42751 contradicts this statement by saying "the double-acting paddle we must have." I have no hesitation in saying that the paddle principle is a modification of the bird impelling its path obliquely upwards by its screw-wings and concave supporting surfaces. In short, the screw for elevation and propulsion in conjunction with curved surfaces reproduces faithfully every movement of the flying animal.

It may, no doubt, interest J. Sutcliffe (letter 42803) to know that, regarding the question of the elastic requirements of artificial wings and aërial screws, I made two wings of similar dimensions, one being more elastic and flexible than the other. I found that the more plastic screw, whilst forming a powerful propeller, broke when beaten vertically with great force after awhile; but the other stood the ordeal splendidly, showing that, although the wing must contain a certain degree of flexibility, rigidity at the inner half must be to a certain extent maintained to enable the wing to "wedge" itself forward; at the same time it is equally imperative that it should yield to evade the air in the beats or strokes.

Respecting his other query: Large birds of prey, such as hawks, vultures, eagles, and condors, have large, broad, ample surface wings, the beats given being slow and stately. Such birds fly higher, and sustain the longest flights. The condor of the

Andes will soar to an altitude of five miles, as is well known. I quite indorse this contributor's opinion as to limitation of the diameter of the screw propeller.

Letter 42802 is very interesting, as, indeed, have been all letters recently inserted in the English Mechanic on this subject. At the same time, I would like to mention that this writer's views are a trifle romantic when it is mentioned that future flying craft will be specially made for sea and land service. In my opinion, considering they will be made all on one system (the screw), it is immaterial whether the projected cruise aloft will be above the sea or land, so long as due precautions are taken to prevent a sudden breakdown of machinery and retard a sudden fall, independent of the suspensory helices, which could only be insured by curved supports.

In reply to letter 42804, respecting the valvular or Venetian-blind principle, I may point out this system is neither original nor practicable, and is at variance with natural laws or types. It is immaterial, in my judgment, whether or not the feathers open in the up-stroke and close in the down-stroke, so long as the wing is plastic and yields (as before described in letter 42704), and evades the resistance of the air. It is not my contention, however, that the feathers do not, for assuredly they do. Mr. G. Dixon terms the feathers "pinion feathers." They are, it may doubtless interest him to know, called "primary," feathers, others being classed as "tertiary," "secondary," "coverts," "sub-coverts." I assure him that it matters not that the feather is broad and narrow respectively on each side, and neither does it insure wholly flight. Flight is attained by impulsion caused by the anterior or front margin of the wing being thicker and graduating compared to the posterior margin or rear half. A writer in October last published sketches of a similar conception, which, however, whilst decidedly advanced, yet contained inherent defects, in that safety was considered insured by concavity of surface only, instead of reversing planes, plasticity, &c.

In conclusion, whatever system is advocated—paddles, artificial wings, aëroplanes, &c.—all are modifications of the one true principle which evolution would conclusively show—to wit, aërial screws plus curved supporting surfaces. **E. Wilson.**

[42864.]—I have been looking up numbers of "E. M." as far back as 1869, and it seems to me the power required in a flying machine is nearly lost sight of. F. H. Wenham, in his splendid letter (42737) does not make it clear to my understanding when he says 3H.P. per 100th raised.

Can any reader give any information on this point? I have two machines in model which I can guarantee will fly, but am short of suitable power. Please see my address in "Wanted" Column.

Ureka.

WATER SUPPLY OF GLASGOW.

[42865.]—In your issue of Sept. 8, 1899, on. p. 87, appears a paragraph relating to the above, being a notice of an article on the subject by Mr. Benjamin Taylor in the *Engineering Magazine* for September. There can be no doubt, from the figures published, that the inhabitants of the Scotch Metropolis enjoy a supply per head considerably larger than that provided for the Londoners, and that their water-rate, is moreover, only about 37 per cent. of what we pay in London. But it is very questionable whether the water obtained from Loch Katrine can be described as the "purest in the world." Two quotations from a very interesting volume, "Shadwell's London Water Supply," should be noticed. On p. 62 we have, "Glasgow, which has a very large and cheap supply; but then Glasgow does not filter its water, and *the typhoid death rate is double that of London.*" (The italics are mine.) Again, on the next page, in a statement as to purity, we have given us in the form of a table—

Comparative Analysis in Parts per 100,000.

—	London. Organic Carbon.	London. Organic Nitrogen.	Birmingham. Organic Carbon.	Birmingham. Organic Nitrogen.	Glasgow. Organic Carbon.	Glasgow. Organic Nitrogen.
June ..	·107	·014	·260	·050	·126	·011
July ..	·091	·012	·180	·050	·128	·011
Aug. ..	·084	·012	·120	·050	·175	·011

An examination of "The Purification of Public Water Supplies," by John W. Hill, which was reviewed in *The Engineer*, Aug. 25, 1899 (page 187), would probably throw further light on this matter. In this work we find the statement that filtration in London "probably averages less than 1·5dol." (per million gallons). The conclusions which the author draws from a comparison of the typhoid rates of large towns in his own country (United States of America) and in Europe, are totally adverse to neglect of filtration, and this, in spite of the fact that, as far as filtration is concerned, America stands at the bottom of the list.

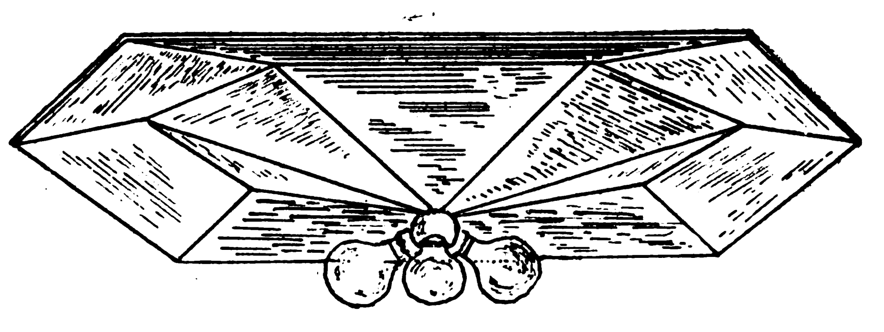
Strathmore, Chiswick, W. Sept. 13.

A RAY DIFFUSER.

[42866.]—I inclose a block of a ray diffuser for electric-lighting, designed to disperse the light, making it particularly suitable for street-lighting, as it prevents dark spaces between the lamps. It is



glazed with silvered fluted glass in sections, so is inexpensive to maintain, and does not tarnish like silvered copper, or become non-radiant like enamelled iron. I thought it might interest some of your readers. The illustration represents the diffuser canted to show the underside.

LATHE MATTERS, OVERHEADS, &c.

[42867.]—By the merest chance I have had sent to me a few numbers of the "E. M.," for I am sorry to say I have left off taking it regularly; and also that I have parted with my many back volumes: hence I cannot refer you to the volume containing an article and diagram of an overhead motion now some years old, for which I at once threw away my overhead motion in the old and usual system, and after years of experience have never regretted it. I feel somewhat ashamed at not having written you before on this subject; but, *of course*, have lots of excuses ready.

Now this overhead (42519), which "South Australian" has just *devised*, seems to be identical with the one illustrated by you, and from which I took mine, and I thank God for it; for as a friend to whom I showed it, and who at once imitated it for his own lathe, said, "It is like the Waverley pen—a boon and a blessing."

As the description given by "South Australian" may not be sufficiently explicit for all amateurs to work from, I try to suggest that you will refer to the number of "E. M." and diagram for the benefit of your many readers who desire to use an "overhead," if they could only rig up an inexpensive and effective one. *Now this is both.* As a clue, I believe the volume was in the "'80's," and the diagram (most simple) and description was by a writer with a Polish name, beginning, as far as I can remember, with a P——. The only alteration I found advisable was to make the frame travelling on the supporting bar capable of being "locked" at any desirable point, as otherwise it had a tendency to "run" in the direction the cord was being driven;—it was then, and remains, *a perfect* overhead motion. My pulleys are all of hard wood, and after years of wear are as good as the day they were made. My "gut" is simply a piece of logline with a long splice; and if this is well made will last for years, for the tension being so constant and regular, there is, in a sense, no strain or wear. Of course, any suitable piece of cord or rope will answer the purpose, and is always ready to be set to work in any position by the simple employment of leading pulleys on the drill motion on slide-rest—i.e., parallel to lathe centres, at right angles, or vertical, and any intermediate position. The degree of tension is always regular, and can be increased at will by the weight for the purpose. I have never found it necessary to alter this weight. I have not found it necessary to have "all the pulleys constructed as snatch-blocks," for the cord can be unshipped and hung up in a moment, and the lathe driving-cord put on. Nor is it necessary all or any of the pulleys on the overhead should "swivel." The cord will be led by leading pulleys on drill motion at any angle; but the frame carrying the two pulleys, which are movable along the bar, is made to "swing" at right angles to lathe, about which there is no difficulty if "the supporting-bar" is round (mine is a piece of 1in. gaspiping, light, and quite stiff enough, with wooden knobs at ends as a finish), after the manner of a curtain-pole. The whole thing is most satisfactory, works easily, is always ready, and can be driven at any speed. Mine is usually driven from 1,500 to 2,000 revs. per minute, and will do the most perfect work on any material. I do not have main cord pass "through sheave in weight," but round a pulley on the supporting bar, which is pulled taut by small chain over fixed pulley at right-hand end of lathe, to which weight is attached. After years of work, I have not found anything wanting in this arrangement; therefore I call it perfect.

One other point in lathe matters deserves consideration—viz., the driving, or, say, treadling arrangement. Where the lathe is driven by power even, the workman might be allowed to sit at his work, especially in work where there is much manipulation of the slide-rest, as is the case in all ornamental work. Now, amateur turning is very laborious with the old treadle, and it is not always convenient or pleasant to have someone else to treadle, and I think it is much on account of this hard labour that many give up turning. It becomes almost an impossibility in the warm weather at home, and nearly always so in Tropical countries, when it is often as much as one can do to lie down comfortably to avoid the feeling of "can'tstand-upatittishness," without toiling at a treadle whilst standing on one leg! This is easily avoided by the use of the velocipede-seat and treadles, as in the American lathes sold by Churchill (Brown and Sharp's, I think), with which turning becomes a pleasure instead of a toil. Moreover, a temporary seat at the back of the lathe enables an assistant to treadle without being in the way of the turner, when it is necessary on special occasions, which I find are very rare with an amateur. I am in a good climate, but my workshop is for weeks 84°; yet, although in my 69th year, I can, and do, work at my lathe eight or ten hours a day without fatigue. Now this I certainly could not do without a velocipede seat and my overhead motion, to which I owe great pleasure and amusement. My lathe is a sort of *multum in parvo*, with which I can do almost anything in the way of ordinary turning and screw-cutting on a 4½in. lathe—circular-saw work, fret-sawing, milling, ornamental work, with overhead motion and eccentric chuck (which latter I made myself), emery grinding, and, indeed, anything that could be expected from a lathe. I have a micrometer screw working in large cog-wheel on spindle by which I can divide to almost any number up to 4,200, and move my work round slowly or to any portion of a revolution whilst my drill motion is doing its work. My "jims" are always open for anyone to inspect, and I take the greatest pleasure in imparting such knowledge as I may possess from experience. I should have sent you specimens of work and drawings of my "jims" long ago but for the consideration of time and distance.

Bhowalie, Kumaon, N.W.P. India.

DEAD-CENTRE LATHE—WORK TRAVELLING OUT OF CENTRE.

[42868.]—I have made a small dead-centre lathe. With this I had fondly expected to be able to turn up the thumb heads of binding and levelling screws, resistance plugs, and the other small brass articles which the electrical amateur is always using. I find, however, that things do not work quite so smoothly as I anticipated, and as I have no doubt there are still a great many amateurs who use a dead-centre lathe, I trust I shall receive a few hints as to how to get over the difficulties which have presented themselves to me. So far, I have only worked on brass, using ⅜ and ⅝ wire. The flywheel of lathe weighs about 35lb., and the power is taken off a small band-wheel 7in. diameter, fixed on the crank. The wheel on mandrel is 2in. diameter; poppets are hard wood faced with ¼ iron, and firmly fixed by means of bolts and fly-nuts; mandrels ½ steel, and points of centres exactly opposite each other. I give these details to show there is no vibration or wobbling of parts.

Now, my difficulty is this. After most carefully finding centre of a piece of brass wire, and drilling deep holes in same, I find that after applying the turning-tool for about a minute or so, one or both the centre-holes appear to travel towards one of the sides, and the work, instead of being round, soon presents an egg-shaped section. What is the cause of this, and the remedy?

I have used the lathe very successfully as a drilling machine. I have a mandrel with a hole at one end instead of a point. I take a twist-drill of desired size, attach a carrier to it, and rest the end in the hole of mandrel mentioned above. Then I rest the work (it must be something moderately flat) against the tail-stock, and press it against the point of the drill. Of course, it is all guesswork as to whether the drill is exactly perpendicular to the work, although it is not difficult to get it fairly so by running the eye along the drill and getting it into line with something straight, such as the slot of the lathe-bed. I find it very difficult, however, to fix very small objects in position against the tail-stock. They twist about in all directions, unless securely held by the fingers. I suppose that when dead-centre lathes were more popular, there were many little contrivances used which have now gone out of fashion. Perhaps some of your readers can offer a short description of some of them.

I should also like to know what is the most suitable sized tool for small brass articles, from ¼ to ⅛ diameter? So far as I have been able to find, a large-sized awl well hardened appears to cut much better than the tools described as "turning tools."

Dead Centre.

SIR MICHAEL FOSTER'S ADDRESS.

[42869.]—In letter 42815, p. 115, the printer omits at the end my reason for saying "Christians ought to have" anticipated Darwin's famous book. What I said was, that they should have seen the true or Biblically revealed "origin of species," which was never by "natural selection," which only preserves a species when it has appeared, but cannot originate anything. The very title of Darwin's book was ridiculous. The first man, the first ox, or the first of any new species, originated as Christ did, by birth from a virgin. A most important step in biology has been made since Darwin's time, though totally ignored by Sir M. Foster in p. 106; namely, the discovery that among the lowest animals are some that are now individually born sometimes of virgins. What was supposed an *unparalleled miracle* in Mary's case, is now seen to be still natural among the lowest creatures, making it far more credible.

Again, Sir Michael Foster totally omits an astronomical fact only discovered in this century, and the latter half—namely, that in all probability the *sun is younger than the earth.* It is connected with the relative densities of the planets, which were supposed half a century ago to be partly denser than the earth. It is now certain that the earth is the densest of them all, which makes her very probably the oldest. This entirely reverses a point in which science was popularly supposed to clash with the Bible. The earth is also the largest of all bodies that can be proved to be partly solid. All the larger are apparently fluid alone. The sudden appearance of a star in the Andromeda nebula in 1884, and its evident cooling down till invisible half a year later, was also most providential in illustrating the book of Genesis.

Sept. 15. **E. L. Garbett.**

THE NUMBER 666, AND INTEREST.

[42870.]—With regard to "Glatton's" first question on p. 116, I cannot find in any margin to Daniel viii. the word *prosperity.* So I cannot tell what word he means. In a concordance to the LXX. no such noun as 'εὐπορία appears, but only the verb εὐπορέω, and this only twice. I should not be running this to death if a single bishop, or priest, or deacon in the last *fifty-five years* (to say nothing of the S.P.C.K.) had taken the slightest notice of Taylor's discovery. It is only their studied silence thereon that drives me to smell brimstone.

Mr. Monck, on p. 117, seems rather to attack H. George, who takes but one of the Earth-Beast's two horns for attack, the use of land as capital, and not of movables. I call anything "*capital*" that is used *against* labour, not in partnership with labour, as Joseph's Pharaoh used it. What is used *with* labour ceases to be capital at once.

Demetrius artfully addressed workmen as if the εὐπορία were theirs as well as his. But that is the constant trick of capitalist speakers everywhere. Certainly neither in the parable of Talents nor of Pounds were the servants capitalists for a moment. The master tried how they would add to the value "by *trading*"—that is, by working at their trade, but certainly not by hiring wagelings to fleece them of profits. If one had said, "Lord, thou gavest me five talents. Behold, I went and hired poorer men, and of their industry have gained five more," he certainly would not have entered "the joy of thy Lord," but have been imprisoned as a thief till restoring his victims their profits to the uttermost farthing.

The crime of capitalism doubtless was practised abundantly long ere Franklin lived; but I doubt if anyone before him taught that borrowing at 6 per cent. per annum (or any lesser rate) was obtaining "all the advantage that there is in possessing money." He was not believed in his economic doctrines *because* of the electric discovery, nor was the latter regarded as a miracle; but neither does the prophecy imply this connection. It simply says that wonders, even to the extent of "making fire descend from heaven to the earth in the sight of men," will be done by a teacher of this heresy.

From 1700, half a century before this sign, till Ruskin's time, I know of no teacher hinting at the difference between capitalism and the honest use of wealth. I have seen an old book on the "Right Use of Ritches," but that was dated before 1700. As soon as ever the lord bishops gave consent to the damnable crime of a National Debt, our Church at once, as Ruskin says, "both renounced the Biblical Jehovah, and flung his Bible in his face." Till then, from the Reformation, Protestantism had been the truer Christianity; but thenceforth, till 1872, I regard Popery as the truer and less idolatrous. Its idolatry was what the Koran attacks as *associating* other objects of worship with Allah; but ours was rejecting him and *substituting* another god, which is far worse. But at length our god of εὐπορία came in 1872 to be adopted by Pius IX. when he had ceased to be a king and become a prisoner. Popes now define the crime of usury as getting 3 per cent. per annum or more; but they had never previously contradicted the Bible thereon. Of course they utterly misunderstood it. The crime, as Mr. Monck says, is now chiefly by borrowers; but the Bible forbad lending and not borrowing, because lenders alone have the power of preventing both.

The difference between letting on the *metayer* system or on ours, I, of course, regard as entire, and involving such flat contrast of direction that, as Carlyle said, "If you continue both lines far enough, they lead to heaven and hell." But I do so far receive the Mark of the Beast as to take the legal National Debt interest of 2¼ per cent., or 3 if possible, but always confessing it as such; and the receipt of a farthing more I regard as most damnable theft. Paying more or receiving more equally criminal.

Sept. 16. **E. L. Garbett.**

MICRATOMIC ETHER.

[42871.]—Those interested in the subject should read Prof. Poynting's address to Section A of the British Association. I agree with much of it, but strongly object to his statement that the Kelvin vortex-atom theory gives a *simplification.* Where many hypotheses are offered preference should be given to any tending to simplicity, especially as in considering varieties of matter we are trying to get at the simplest forms or conditions thereof. In attempting to analyse complex matter we simplify step by step until we reach molecules or chemical atoms. If at present we cannot practically analyse further, there is no reason why in theory endeavouring to analyse further we should proceed to increasing complexity instead of simplicity.

I scarcely think "J. M. W.," letter 42787, imagines the ether to be mere motion. There is motion, and there is something which moves; I call that something "matter," however different the matter of ether may be from other matter, gaseous, liquid, or solid.

In reply to R. A. Kennedy (letter 42788), I may say that in my opinion sound *in transit* is not capable of polarisation like light. In ordinary treatises on sound, the action of sound *in transit* (through air, for example) is confusedly and, in my opinion, erroneously mixed up with the actions by which sound is produced or started—that is by which the succession of impulses constituting sound in transit are originated.

I thank W. Howse (letter 42825) for his criticism of "J. M. W." As to sound and colour, however, I may say that many years ago I made careful experiments which showed no correspondence whatever between particular notes and particular colours.

Lucretian.

HEAT AND GASES.

[42872.]—I wish to thank our Editor much for allowing us a little space to gain information on the effect of heat on gases, and on that to me wonderful point "absolute zero." I wish also to thank the correspondents who have been pleased to offer assistance. I beg to ask some questions on the theory of the above in this letter, and possibly the replies will enlighten others as well as myself who have not especially studied either light or heat. Anything from the pen of "J. M. W." or "M.I.C.E." will be esteemed a favour. The quotation in letter 42807, p. 93, is taken from "Elementary Hydrostatics," by W. H. Besant, M.A., F.R.S., lecturer and late Fellow of St. John's College, Cambridge, dated 1875, art. 84, p. 75 (Deighton, Bell, and Co., Cambridge).

I also find stated there that Regnault's results for different gases varied from ·003665 to ·003689. I also find in a small book on the "Theory of the Steam Engine," by Baker, that the increase in volume from 32° F. is ·00202 of its volume per degree Fahr., according to Gay-Lussac, which is equivalent to ·003636 C.

From the same book I quote the following: "From the experiments of Regnault, it appears that air expands 0·3665 of its volume at 32° of Fahrenheit by being heated from that temperature to 212° on the same scale." Now as raising from 32° Fahr. to 212° Fahr. is the same as raising from 0° C. to 100° C., we find that Regnault got the ·3665, which divided by the 100, gives probably his method of obtaining the ·003665.

What I wish particularly to know is, has the same result been arrived at by sufficiently correct apparatus by raising the temperature of a given mass one degree at a time? Here I will call attention to the formula arrived at in letter 42807, p. 93, and substituting ·003128 instead of ·003665, then by taking $M = V r^n$, we should get for a rise of 100° C. the increase of ·3665 of its volume. The ·003128 would, according to the ordinary method of calculation, be an error to the amount of approximately $\frac{1}{2000}$ of the volume at 0° C.

Taking the ordinary method of calculation, I cannot quite agree with Mr. Webb, letter 42818, p. 115, that "At 100° C. the volume would be $\frac{100}{273}$ of its volume at 0° C.," as at + 100° C. I make it $1 + \frac{100}{273}$ of its volume at 0° C., and at − 100° C. I make it $1 - \frac{100}{273}$ of its volume at 0° C. *I fear* others may share my faults.

I am not allowed to assume that an increase of one degree in temperature in a given mass of air increases its volume at any named temperature by a fixed percentage of that volume, the pressure being constant; but the following pill I must swallow—viz., that in a given mass at − 272° C. an increase of 1° C. *doubles* the volume, whilst at + 273° C. an increase of 1° C. only increases the volume by $\frac{1}{546}$ of that volume.

Any information bearing on the foregoing, together with notices of books on the subject, will be esteemed a favour. **William E. Tanton.**

USEFUL AND SCIENTIFIC NOTES.

The total mileage of the railways in the United Kingdom in 1878 was 17,333, and the paid-up capital 717 millions. In 1898 the mileage had increased to 21,659, and the capital £1,134,461,000. Thus the mileage has increased in this period by 4,326, at an additional capital cost of 417 millions sterling.

With regard to sprinkling railway lines with petroleum, it is reported from America that an additional advantage has been found since moisture will not penetrate through the oiled outer crust. Instead of this the water runs off the track into the ditches at the side of the road. Vegetation along the sides of the rails is destroyed by the application of oil, and thus a saving of labour is effected.

It is reported from New York that the keel of the largest merchant steamer ever built on the Pacific coast has just been laid down at the yard of the Union Ironworks, San Francisco. The length of the new vessel is to be 450ft., and she is to have a beam of 51ft.; her carrying capacity is to be 8,250, and her displacement 12,000 tons. The new vessel is being built for the American-Hawaiian Steamship Company.

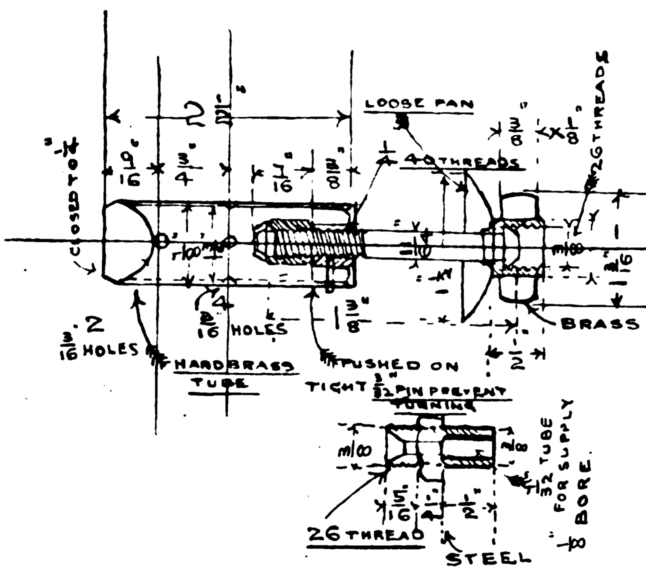
Cast aluminium is about equal in strength to cast iron in tension, while under compression it is comparatively weak. With a purity of 99 per cent. the ultimate tensile strength of aluminium per square inch is, in castings, 18,000lb.; in sheet, 24,000lb. to 40,000lb.; wire, 30,000 to 55,000lb.; and in bars, 28,000lb. to 40,000lb. The elastic limit of aluminium of this purity is, for castings, 8,500lb.; sheet, 12,500lb. to 25,000lb.; wire, 16,000lb. to 33,000lb.; and bars, 14,000lb. to 23,000lb. per square inch. Taking tensile strain in relation to weight, pure aluminium is as strong as steel of 80,000lb. per square inch.

The Lords of the Admiralty have decided to strengthen the fleet of tugs at Devonport by the addition of a vessel to be built by the London and Glasgow Shipbuilding Co., Glasgow. The new tug, which will be larger and more powerful than any tug yet built for the naval service. Her dimensions are: length, 144ft.; breadth, 27ft. 3in.; mean load draught, 10ft. 9in.; displacement at load draught, 700 tons. She will be constructed on the ordinary paddle-wheel principle, in order that she may be of greater service in shallow water than if fitted with propellers. Her engines are to develop 1,250I.H.P. on an eight-hours' trial, under which conditions the vessel is expected to attain a speed of 12 knots per hour.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96374.]—**Lamp for Firing Tube Motor.**—Sketch shows latest pattern for pressure burner for lamp ignition. You will want to drill within $\frac{1}{32}$ of



top of nipple, then punch hole through with a needle threaded through a cork. The nipple tube must have a hole $\frac{1}{32}$in. through it, and inside fill with a plug made of finest possible copper wire gauze rolled up tightly on a piece 20-gauge steel wire 1¼in. in length. MONTY.

[96457.]—**Widened Railway Carriages.**—The coaches on the Midland Railway running on the Tottenham branch and also to St. Alban's (local trains) were made to seat six on each side of a compartment, about fifteen years ago. At any rate, I know that I travelled in them in 1883 daily, and the paragraphs going round about the improvements introduced by the Great Eastern are simply "slop." But is it right to speak of it as an "improvement" to crowd six passengers on a seat by adding about 8in. to the width of a carriage? The simple fact is that the traffic has grown so enormously that the railway people do not know what to do to meet it. METOPS.

[96458.]—**Silver Coins.**—It is quite true that silver coins anterior to the date of the Queen's accession are refused at many places (I speak from personal experience), but, of course, the blunder lies with those who refuse them. The Bank of England (by courtesy) will always change worn silver tokens (shillings, sixpences, &c.), but it will not change those coins which have had a hole made through them. Personally, I think the Government Post-offices ought to be compelled to change the worn "coin," and it might be made a condition of a license that worn tokens should be accepted, because they are easily sorted at a bank. That is done—sometimes. A coin that is not defaced can be changed at the Bank of England. S. R.

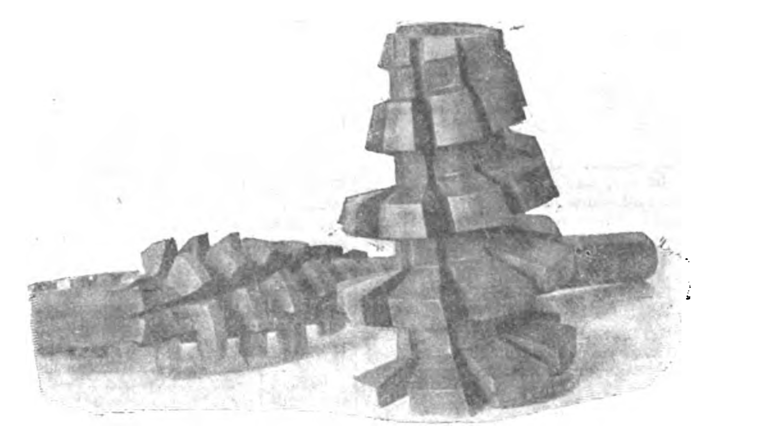
[96471.]—**Loan Amortisation.**—I regret that at lines 31 and 32 of my reply (p. 118) are errors of computation. "The equal annual repayments for 44 years for a loan of £1,000 at 4½ per cent. there stated to be £59 6s.—viz., £45 for interest, and the surplus £14 6s. to be reinvested to replace capital" should read respectively "£52 11s. 7d.—viz., £45 for interest, and £7 11s. 7d. to be reinvested at same rate of interest to replace capital." There is an error also in my estimate of the rate of percentage in the building society transaction. "Garsdale" in the next answer gives a correct reply to this part of the question. A. H.

[96488.]—**Pitch of Worm.**—A very neat and efficient method of measuring the pitch of screws and worms, as described by "H." in the issue of 8th, is to place them on the scale in the sun in such a manner as to get a clearly-defined shadow of the threading on the graduation. JERSEY.

[96504.]—**Macadam.**—This query seems to have been unnoticed, and probably those who are responsible for what are called macadam roads are in sublime ignorance of what is wanted. A macadam road, properly made (that is the point), is as good a road as can be desired; but where do you find one properly made? Macadam gave his directions as plainly as possible; but, strange to say, those directions are just what modern roadmakers will not follow—they know better, and they make more work. J. L. Macadam stated distinctly and expressly that the broken stone, whether flint, granite, whinstone, or what, should not be in larger pieces than would weigh 6oz., and pieces of one to two ounces are to be preferred; but our modern roadmakers use pieces weighing a pound and more, and doubtless consider they are improving on Macadam. Result: Mud and muddle. There is no better road than a well-made "Macadam." S. R.

[96555.]—**Equations.**—I am obliged to Mr. Burgess for his reply to the above; but his method of solving is not satisfactory, as he assumes the value of x, which has to be found. I had previously obtained the same roots by assuming them to be in arithmetical progression. But these are not mathematical methods of solution, and as all writers agree that, given the same number of equations as the unknown, a solution can be found without any guesswork, thus this problem ought not to be any exception to the rule. Perhaps Mr. "C. J. M.," or "Scorpio," or Mr. J. S. Vincent would favour the writer with a reply. Most of the devices given in the books on "Theory of Equations" and "Higher Algebra" have failed to obtain a solution of this problem. J. HARDING.

[96602.]—**Cutting a Worm-Wheel.**—Yes; in the first place, the shape of the hob is wrong. Your pattern commences cutting at the point of the worm, whereas it should commence at the root. Taper the hob off as per the sketch (borrowed from



Reinecker's Catalogue) and commence cutting with the smallest diameter of the worm, gradually traversing towards the largest end. As the cutter has to rotate the wheel, the teeth seldom come out as desired, and I would advise you to divide the wheel into 50 parts. This can easily be done with a change-wheel. Now with a narrow cross-cut chisel chip 50 spaces out, slightly at an angle. You have got 50 teeth, and none of the playfulness of the hob will give you more or less, so you can proceed with the hobbing with success. CLYTIE.

[96600.]—**Astronomical Signs.**—In reply to the question, "Where the Signs of the Zodiac Originated?" it seems that some time between the Flood in 1656 A M. and the Confusion of Tongues in 1771, the heavens were arranged into constellations. We find this to be so by the constellations then on the Equinoxes. Again, all the constellations are in the North, and none in the South. This fact shows that the persons who arranged them lived in, or not far from, Babylonia. We are, indeed, told by great Jewish writers that the constellations were mapped out by Noah soon after the Deluge. But if F. C. Lambert writes to Observatory House, Wanstead, E., he will get a lot of information about the Zodiac. All the eclipses wheel round it like the hands of a clock, for which reason it is a dial-plate of all time.

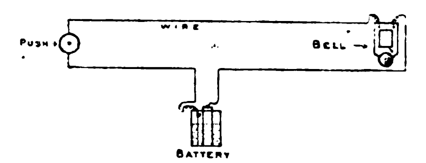
MEMBER OF BRITISH CHRONOLOGICAL AND ASTRONOMICAL ASSOCIATION.

[96604.]—**Transformer.**—No; not by a transformer in the ordinary sense of the word. To transform a continuous current to higher or lower potential a "motor-generator" is necessary—i.e., a machine similar to a dynamo, but with two separate windings to the armature, and two commutators, one being fed as a motor, and the other delivering current as a dynamo. The amount of transformation effected in the voltage depends on the proportioning of the two armature windings. A No. 4 Lahmeyer dynamo could be adapted for this purpose, and I can give "E. A. W." particulars on receipt of his address. But why not accomplish the desired object by charging accumulators in parallel, and then rearranging in series?

A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96604.]—**Transformer.**—You cannot use what is commonly called a transformer, it being only operative with alternating currents; but you could use a Booster, which is simply a motor and dynamo combined, the armature being wound with two sets of wires—the one heavy, to take the large current of the dynamo and cause the motor to rotate; the second finer, and generating a current at an increased voltage through the rotation of the armature. There is very considerable loss in the double transformer, quite 30 to 40 per cent. You would probably get a better result by winding a spare armature to give the required voltage, and inserting a corresponding resistance in the shunt circuit. So altered, the dynamo should light five 16c.p. lamps. W. J. G. F.

[96606.]—**Defective Battery.**—First soak the porous pot in water for about two hours, then



dissolve 4oz. of salammoniac in 1 pint of cold water, and fill glass jar to within 2in. of top, and your battery will be ready for use. If you connect it up as per sketch, you will find it work all right; but for practical work you will want two batteries. S. ELLIMAN.

[96614.]—**Charging Pocket Accumulator with Small Dynamo.**—Dynamos with Siemens H armatures will not charge accumulators; but an armature of the tripolar type could easily be substituted at a small cost, and the machine would then do all that you require.

A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96614.]—**Charging Pocket Accumulator.**—If the dynamo is shunt-wound, it is possible to charge the accumulator, but very difficult. The commutator slit must be quite parallel to the axis and abnormally wide; so that the brush will be quite clear of the one segment before making contact with the other: otherwise the cell will be short-

circuited every half-revolution, and no charging will result. W. J. G. F.

[96618.]—**Reducing Temperature.**—Put in an electric fan. A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96619.]—**Electric Organ.**—I am interested in "Diapason's" remarks as to the balancing of harmonium and organ reeds with organ-pipes. As an amateur I never could quite understand why this cannot be done. Reeds form some of the most beautiful stops in most organs, though they are not very often found in chamber-organs. Is it to be inferred that the particular construction employed tends to harmoniously reduce the errors due to temperature, or are such errors tolerated but corrected by more frequent tunings? I have experimented a little in this direction, using the 16ft. reeds "Bourdon" in a very old and fine-toned French harmonium, and these have a very mellow and rich tone, and blend well. I raised the wind-pressure and revoiced them, thereby getting rid of the drone peculiar to heavy harmonium reeds, and causing them to speak up crisply. So far I have been encouraged, and I am now on with the 8ft., and have put in two stops on vacuum which are bright and mellow. Unless "J. S. Z." is a practical electrician, I advise him to let electrical actions alone; when used, they must be well made, the magnet cores annealed and carefully wound with paraffined wire, and the contacts so made as to be unaffected by corrosion or oxidation due to sparking. Some day currents of greater certainty and volume than those obtainable from any battery may be had from the street mains, and then direct electrical actions will be possible. I have tried this form upon small pipes, and they work promptly enough—so much so that I doubt if motors could be used for part of the action with it, as their inertia causes them to lag. If "J. S. Z." couples up his instrument, let him still keep it independent, and if it can be done, use tubular pneumatic action. This can be readily made by a careful amateur. He could then play his organ from its own, or the American organ manual, and that without injuring either. ELECTRICIAN.

[96621.]—**Warts.**—Ask your chemist for some "Liquor sodii ethylatis." It should be freshly made, as it does not keep good many weeks. It destroys anything in the way of warts or growths, such as moles standing above the skin. Paint the wart carefully, and it will probably come off next day. If not, repeat the application. GLATTON.

[96623.]—**Steamer.**—The *Empress Queen* was built by the Fairfield Company in 1897 for the Isle of Man Steam Packet Co. Her gross tonnage is 2,140 tons. She is fitted with compound engines, developing about 10,000I.H.P. Her registered dimensions are:—length 360ft., breadth 42·3ft., and depth 17ft.; length over all 375ft., breadth across paddle-boxes 83½ft., moulded depth to spar deck 25½ft. She has four decks—viz., spar deck, main deck, lower deck, and 8ft. above the spar deck is a promenade deck 210ft. long, which reaches from fore-end of boiler room to the aft-end of first-class cabin. In the first-class dining saloon on lower deck there is accommodation for 124 passengers; besides this saloon, there are cabins, fitted with sofas, a social hall on main deck, and a ladies' first-class saloon. The second-class accommodation is situated at the forward-end of the vessel, and consists of a dining saloon on lower deck; also a pantry, bar, and a little further forward a ladies' second-class dining saloon. On the spar deck are several private berths, cabins, and deck-houses; also a cloak-room and smoking-room and bar combined. The vessel is fitted with electric light, and has two navigating bridges, one forward and one across paddle-boxes. Her engines are of the compound diagonal surface condensing type, having three cylinders, the h.p. one in the middle, with a l.p. on each side of it. The h.p. cylinder is 68in. in diameter, and the l.p., each 92in. stroke, 84in., pressure 140lb. In her speed trials she made 21¾ knots in a heavy sea. She now runs from Liverpool to Douglas in from 3½ to 4 hours. For further information, with plans of steamer, "A. G." should refer to the *Engineer*, Sept. 3, 1897.
RED ADMIRAL.

[96627.] — **Foreign Currency.** — Inquire of Effingham Wilson and Co., Royal Exchange, E.C., for his shilling work on "Chain Rule."
REGENT'S PARK.

[96629.]—**Linoleum Polish.**—A good general varnish may be made thus:—Waterproof, pale shellac 5oz., borax 1oz., water 1 pint. Digest at nearly the boiling point until dissolved, then strain. Or, sandarach 6oz., elemi (genuine) 4oz., anime 1oz., camphor ½oz., rectified spirit 1 quart. When dissolved strain through muslin into bottle for use and allow to settle; heat (water bath if possible) to be applied if wanted. REGENT'S PARK.

[96629.]—**Linoleum Polish.**—(1) Try wiping over with milk, or (2) beeswax and turpentine put on thinly, and well rubbed off. PHILOS.

[96630.]—**50-volt Overtype Dynamo.** — Armature: cogged drum, 4in. diameter by 8in. long, 16 or more teeth, wound with 5lb. No. 16 S.W.G. Field-magnets, 8in. deep by 2in. thick by 4in. clear winding space on each limb, wound with 20lb. No. 19 S.W.G., speed about 2,200 revs., shunt wound and suitable for arc as well as incandescent lighting. A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96631.]—**Eight Queens Problem.**—Here are four solutions, and "Q. R." may like to exercise his ingenuity in discovering some of the other "number of ways." 1. Queens at K sq., K R 2, Q 3, Q R 4, K Kt 5, Q Kt 6, K B 7, and Q B 8. 2. Queens at Q Kt sq., K 2, K Kt 3, Q R 4, Q B 5, K R 6, K B 7, and Q 8. 3. Queens at K B sq., Q B 2, K Kt 3, Q Kt 4, K R 5, K 6, Q R 7, and Q 8. 4. Queens at K sq., Q B 2, Q R 3, K B 4, K R 5, Q Kt 6, Q 7, and K Kt 8.
W. F. WEBB.

[96631.]—**The Eight Queens Problem.**—I cannot see anything vague in this problem, for it is evident that by "pieces" you can use blocks of wood to represent the eight queens, or eight pawns might be used. I send one solution:—

Place a pawn on Q B square
the 2nd „ K 2
3rd „ K Kt 3
4th „ Q R 4
5th „ Q 5
6th „ Q Kt 6
7th „ K R 7
8th „ K B 8

and you will find that no piece can take any other piece by the queen's move. A. TUPMAN.

[96631.]—**Eight Queens Problem.**—This problem, as your querist surmises, is to place eight queens (or pieces having the power of a queen) on a chess board so that neither one can take the other. He will find it an interesting problem to solve, and not so difficult as it appears. There are, I believe, nearly one hundred ways of placing them, but the few I have appended will suffice to prove its possibility—

4 .. 10 .. 24 .. 29 .. 39 .. 41 .. 51 .. 62
7 .. 9 .. 19 .. 32 .. 38 .. 44 .. 50 .. 61
1 .. 14 .. 24 .. 27 .. 39 .. 44 .. 50 .. 61
1 .. 15 .. 21 .. 32 .. 34 .. 44 .. 54 .. 59
2 .. 12 .. 22 .. 32 .. 35 .. 41 .. 55 .. 61

CHARLES BUCKNELL.
258, St. Paul's-road, Highbury, N.

[96632.]—**Motor Batteries.**—TO MR. BOTTONE.—(1) Yes, provided sufficient zinc be added to thoroughly neutralise the acid. But chloride of zinc can be obtained very cheaply in bulk from any manufacturing chemist. (2) Having procured the zinc cylinder with a bottom to it, put a piece of cork, about ½in. thick, across the bottom for the carbon rod to rest on, so as to prevent actual contact with the zinc. Now make a canvas sack of half the diameter of cylinder, and having placed the carbon rod in this, pack it tightly with a mixture of 40 parts by weight of granular black oxide of manganese, 5 parts of colcothar or rouge, 5 parts potassium permanganate, and 50 parts of coarsely-crushed graphite. Now stand this upright in the zinc pot, and ram round tightly sufficient sawdust, previously soaked in the salammoniac and zinc-chloride solution recommended last week, to fill up to within ½in. of top. Pour in the same solution into the sack until the contents will take up no more. Pour off the superfluity, dry carefully round the edges of the zinc, and seal up with melted pitch. When quite cold, with a red-hot knitting-needle make a vent-hole, reaching through the pitch to the mixture below. Solder connecting-wire on zinc. The carbon should, of course, have a terminal affixed to it before placing in sack. (3) The canvas requires no special preparation. (4) The zinc must not be amalgamated. (5) Because unless vent-holes are left, the gases given off during the action of the battery, finding no escape, lift up the pitch bodily. S. BOTTONE.

[96633.]—**Green Water.**—Perhaps your best plan will be to keep a few water-snails (Planorbis) in your bath. S. BOTTONE.

[96634.]—**Injector.**—No injector will work with hot water. The action of an injector is partly dependent upon the sudden condensation of the steam by the inflowing water. If the water is too warm to effect this properly, the injector will fail to act. W. J. G. F.

[96635.]—**Solder.**—Malleable solder: Copper 72, zinc 18, tin 4. Readily fusible Argentan solder: Copper 35, zinc 57, nickel 8; or, copper 38, zinc 50, nickel 12. REGENT'S PARK.

[96636.]—**Accumulator.**—Cut three plates out of sheet lead, about ⅛in. thick, 3½in. by 1½in., with a short lug at one corner for connections. Punch each plate full of holes about ⅛in. in diameter, and afterwards countersink all the holes on both sides with an ordinary joiner's brace and countersink-bit. Take two parts of water, and into the water pour slowly, and with constant stirring, one part of strong sulphuric acid. Take as much red lead as will serve to paste one of the plates, and make it into a stiff paste with the sulphuric acid and water. Lay the plate on a flat surface, and work the paste well into the holes, first from one side and then from the other, with a flat piece of wood, and afterwards smooth off the superfluous paste. Allow the paste to harden for twelve hours, and then immerse the plate in a strong solution of bleaching powder till the paste has turned a dark chocolate colour. The positive plate is now ready. For the two negative plates make up a strong solution of lead acetate, and in it hang several pieces of zinc by threads. In some hours the zinc will have dissolved, and the lead will have been thrown down from the solution in the form of fine crystals. Paste the two negative plates with this. Bend two short lengths of fine glass tubing into the shape of a long U, and having washed the positive plate quite free from chloride of lime in a gentle stream of water, slip the two pieces of tubing over it, and then place a negative plate on each side, and join their lugs together by soldering. Vulcanite makes the best containing cell for so small an accumulator. Fill the cell with a mixture of two parts of water to one of sulphuric acid. The three plates will give about 2½ to 3 ampère-hours at 2 volts. W. J. G. F.

[96636.] — **Accumulator.**—"Mousetrap" will find all the necessary information in "Small Accumulators," published by Dawbarn and Ward, 6, Farringdon-avenue, E.C., price 7d. Instructions have been given, too, times without number in back volumes. A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96638.] — **Electric Lamplighter.** — TO MR. BOTTONE.—Procure two good dry cells, size about 6in. by 2½in. diam.; connect these up in series with a little push, as used in ordinary bell-work. Arrange in connection with these two stout copper wires, not touching, but bridged across, just over the wick of the spirit lamp, with about ¼in. of No. 36 platinum wire. On pressing the push, the platinum wire will become incandescent, and light the spirit-lamp. The addition of a little benzine to the spirit makes this result more certain. If ¼in. of platinum wire fuses with the current (as it will sometimes do if the batteries are very strong), use ⅜in. Ordinary soft iron wire, No. 22 gauge, runs about 15ft. to the ohm. S. BOTTONE.

[96640.] — **Silver-Plating — Sand-Bag.** — TO MR. BOTTONE.—Take 2oz. of nitrate of silver and dissolve it in half-gallon of distilled water. Now dissolve 2oz. of cyanide of potassium in two quarts of water. Add this latter to the former very gradually, and little by little, as long as farther addition produces a precipitate, but no more. The supernatant liquid clears when this point has been reached. Allow the cyanide of silver to settle, then cautiously decant the clear solution, which is of no use. Now add to the precipitate (which is silver cyanide) sufficient solution of cyanide of potassium, made up as before, 2oz. to the 2 quarts of water, to entirely redissolve the white precipitate of silver cyanide. Lastly, add sufficient water to make up one gallon. For further information, consult Bonney's "Electroplater's Handbook," pp. 115 *et seq.* (2) I know nothing about sand-bags. Perhaps my wife may, if you will kindly specify what kind of sand-bags. S. BOTTONE.

[96642.]—**Irritation.**—Have you tried camphorated oil? This is generally efficacious. Use it only when the pruritus is felt. The application of gall and opium ointment is often very beneficial.
S. BOTTONE.

[96642.]—**Irritation.**—Throw away all ointments, &c. Wash the part daily with soap, and dry carefully. JERSEY.

[96642.]—**Irritation.**—Has J. Hope tried boracic ointment? If not, let him do so. Anoint and well rub in to parts affected before dressing in the morning, and again on going to bed. If not in possession of silk drawers, have a piece of white silk sewn in the fork of those he has, to reduce friction, and if he wears blue serge trousers leave them off till quite cured. Of course, extreme cleanliness is a *sine quâ non.* DESMOND.

[96643.]—**Relief Stamping.**—When counterpart is made, mix colour (on slab, using best pale paper-varnish) to the substance of thin gum, take die out of press, brush colour well into it, exchange into right hand face downwards, wipe off colour on to printing-paper (about a quire of rather rough quarto) on to bench. Do it systematically, so that paper is not wasted. Colour taken off surface, but left in engraved work. Place die in press, insert paper, bring down lever with a sharp blow. If colour on slab and brush get dry, a few drops of turps soon moisten. To keep brushes moist, wrap them in paper after use, to keep air from them. To make impression shine, mix colour a day or two before use, and use no turps. Never let the colour remain on slab, as it dries up. Keep in small gallipots, covered. REGENT'S PARK.

[96645.]—**Arc Lamp.**—TO MR. BOTTONE.—It would take too much space here to illustrate and explain what you require. I may say that no choke coil would be needed. If you care to write to me,

I shall be pleased to lend you a dimensioned sketch of one of the best types of hand-fed arc lamps.
S. BOTTONE.

[96647.] — **Knife - Handle Cement.** — The handles of knives are not meant to be put into boiling water, and I do not think you are likely to find any better cement than the ordinary one; but you might try sulphur, with some brickdust mixed with it.
PHILOS.

[96647.]—**Knife-Handle Cement.**—Mr. Cole evidently knows something when he asks how to fix metal handles to blades of table-knives. I do not know, but I suggest that probably (possibly) plaster of Paris mixed with a solution of alum may be found efficient, or melted alum itself; but that is not easily done. I think the plaster mixed with a solution of alum will do; but possibly waterglass may be better. Good plaster of Paris (such as is used by the makers of casts) seems to "bite" into anything, and the temperature of moulding should not affect the blades; but it is a tedious operation, as the plaster must be mixed frequently. I should try the plaster mixed with alum-water or a decoction of marsh-mallow roots.
M. T.

[96649.]—**Battery for One Light.**—As the candle-power of the "one light" is not specified, it is a little difficult to advise. But supposing it to be a 2-volt battery lamp of about 1c.p., then the most convenient battery is, perhaps, the National dry cell, and it is certainly cheaper to buy these than to make. Two cells will be necessary, and some No. 20 wire.
A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[96649.]—**Battery for One Light.**—Procure an incandescent lamp of the candle-power you require, and of as low a voltage as possible, remembering that every 2 volts means 1 cell of battery, as described below. A convenient voltage is an 8-volt 3-candle-power lamp. For every 2 volts marked on your lamp, you must make up one cell as follows: One zinc plate 6in. by 3in. by $\frac{3}{16}$in., sandwiched between two carbon plates 6in. by $3\frac{1}{4}$in. by $\frac{1}{4}$in., separated above by a strip of ebonite $\frac{1}{4}$in. thick. The outer carbons must be electrically connected by a strip of copper. Attach a terminal to the zinc, and one to the copper strip connecting the carbons. The plates can be clamped together above by binding round with twine boiled in paraffin wax. The sandwich is to be placed upright in a Weston salt-jar, or similar size about 6in. high by 4in. diameter. Connect the required number of cells in series—*id est*, the zinc of the first to the carbon of the second, and so on; and then the first carbon and last zinc to the lamp by No. 16 copper wire. Fill the cells with the following solution:—Water, 1 pint; chromic acid, 3oz.; oil of vitriol, 3oz.
S. BOTTONE.

[96649.]—**Battery for One Light.**—Your query is somewhat vague, as you do not state the voltage of your lamp, which may be anything from two volts upwards. Small lamps can certainly be lit by means of a dry or wet battery; but in the former case the light could only be used at intervals, such as seeing the time at night, &c., as dry batteries soon run down, and do not give a continuous current. A very useful battery suitable for your purpose would be the double-fluid chromic-acid cell. This can be made up as follows:—Procure a large jam-jar, and stand in its centre a porous pot, about 6in. by 3in., into which place a zinc rod (like that used for a Leclanché cell). Now surround the porous pot with the largest carbon plates obtainable, and connect them all by a stout copper wire. Charge the porous pot with sulphuric acid, 1 part to 20 of water, and the carbon compartment with chromic acid 3 parts, water 30 parts, sulphuric acid 3 parts. Such a cell should give about two volts, and three connected in series will light a 5-volt lamp well for about eight to ten hours.
VICTOR E. ARMSTRONG.

[96652.]—**Calcite.**—I am not aware that this particular form of spar is found anywhere else than at the place "Fleur-de-Lys" mentions. $CaCO_3$ also crystallises in rhombic form as "arragonite"; thus it is dimorphous.
B.Sc.

[96656.]—**Bookbinding.**—I have for some few years made a hobby of bookbinding, and consider that the best books upon the subject are the ENGLISH MECHANIC, Vols. LI., LII., and LIII., and "Bookbinding for Amateurs," by W. Crane, published by Gill, 170, Strand, at half a crown. By the careful study of these and a large amount of practice you should be able to turn out very good work. I have found that all the tools absolutely necessary are a sewing press, a laying press and plough, some pressing, cutting, and backing boards, a lettering stove and letters, gold knife and cushion, backing hammer, shoemaker's knife, and a paste-brush and a glue-brush. The most difficult work I have found is the proper cutting of the edges, but with a plough knife properly adjusted you can make a much better job than by any other process. You will see many other ideas for cutting in the volumes of "Ours" above mentioned.
BLUE BEAR.

[96656.]—**Bookbinding.**—Before going in for a press and plough I used to cut edges by pressing straight edge on top of book, and cutting gradually through with a shoemaker's knife kept very sharp. With care a very good job can be made this way. You will find that the use of glasspaper will remove any little roughness that remains after the cutting.
BLUE BEAR.

[96658.]—**Rheumatism.**—If "Finem Respice" has the courage to adhere to the following for a few weeks, he and rheumatism will henceforth be strangers. Let him take a teaspoonful of *kerosine* oil in a wineglassful of water every *other* night, and he or any other person suffering from rheumatism will shortly be free from its pains. It produces no unpleasant symptoms, no loss of appetite, and no effect on the bowels or kidneys. The principal objection is its nauseous taste and smell, but a pinch of salt being put in the mouth and allowed to dissolve and the oil then swallowed will make it less unpalatable.
DESMOND.

[96662.]—**Thunderstorm.**—Faraday, it is said, once attempted to kill a rat by electricity, but failed to do so as long as the skin of the animal was drenched with water. From this it was probably concluded that the safest condition during a thunderstorm was to be thoroughly wet through, a conclusion perhaps not to be taken too seriously. The destructive effects of thunderstorms have indeed never been systematically observed and tabulated, and, although there are numerous accounts of accidents due to lightning, it is not always possible to compare these accounts with one another. But by noticing which trees are most frequently struck by lightning it is possible to learn much concerning the behaviour of atmospheric electricity, and there are reasons for believing that the quality of the soil as regards its mineral constituents largely regulates the destructive effects of lightning. Few observations, however, of "lightning strokes" have much to say concerning the quality of the ground over which any given storm was operating, and it is possible that further information on this part of the subject would do much to explain many of the accidents which occur to animals and trees during violent thunderstorms.
NERPS.

[96662.]—**Thunderstorm.**—It is not the case that a person is in less danger of being struck by lightning when wet than when dry; but it is the case that the danger of being struck is very much mimimised during rain. The air full of rain offers a ready path to the flash, which therefore strikes more or less straight to earth. Dry air, on the other hand, offers great resistance to the passage of the flash, and in following out the line of least resistance the flash may cover quite a wide area before reaching earth. In the case of the man mentioned it was the tree which attracted the lightning. If a tree and a man are at a short distance from one another, the tree being the higher is more likely to be struck; but a man or beast out on flat ground is more likely to be struck than the ground for a little distance round them.
W. J. G. F.

[96662.]—**Thunderstorm**—Cattle in a herd are very liable to be struck by lightning even when wet through, because the body of vapour arising from them increases the conducting power of the air above them. On the other hand, a man is much safer when drenched to the skin. Dr. Franklin was unable to destroy a wet rat with electricity, although he could a dry one. The reason it is risky to stand under a tree is that the discharge between the cloud and the tree may divide, part passing into the better-conducting, dry human body.
B.Sc.

[96663.]—**Wimshurst.**—To MR. BOTTONE.—It is evident from your description that the glass tubes carry the upright conductors. These tubes are really unnecessary, unless you are passing the rods through a glass case; and even then stout ebonite is better. The cause of the discharge across from outside of jars and along the neutralising rods, which must not be insulated, is simply because as the jars are not metallically connected together, as they should be for long sparks, and as they are nearer the neutralising rods than is the limit of their sparking distance, they discharge across to them. Polish your bolts carefully with rouge and chamois, until they reflect like mirrors. Varnish your jars, glass tubes, &c., with good, thick shellac varnish, and allow to dry thoroughly in a warm place. Connect your four jars below by a brass strip, and you will find you will easily get a 7in. or 8in. spark.
S. BOTTONE.

[96665.]—**Coal and Electricity.**—It would be quite feasible for you to generate electricity at the station and transform it into power by motors at your works, and we have no doubt you would effect a considerable saving thereby. You do not give sufficient particulars to enable us to say what the saving would be; but assuming you use 5lb. of coal per I.H.P. hour (a very moderate estimate), you would be using about 1,600 tons per annum (if working 10 hours per day and $5\frac{1}{2}$ days per week), which, at 3s. 4d. per ton cartage, is £266 per annum, equal at 4 per cent. to a capital of £6,700. The cost of two constant-current 500-volt generators of 100 to 125B.H.P. each would be from £800 to £850. You would require eight miles of cable carrying 200 ampères, which would cost £165 per mile = £1,320, and four miles of cable to carry, say, 50 ampères at £60 per mile = £240, and 100 wood poles and fixing, say, another £100. Then the cost of seven 35B.H.P. motors would be about £120 each = £840, totalling £3,350, which at 4 per cent. would be £134 per annum. There must be added to this, however, the cost of moving and re-erecting your engine and boiler at the station. Depreciation would not be more, if so much, as your present system; and as the capital charge would not be increased if your works were running day and night, the cartage on another 1,600 tons of coals for night duty would be entirely saved, so that by working daytime only a saving of £130 per annum would be effected; but if working day and night, a saving of cartage on a total of 3,200 tons of coal = £400 per annum would be effected. These figures are based on the assumption of working at a voltage of 500 and on the three-wire system. This pressure is what is generally used by the electric tram systems, and although not so economical in cables as a higher voltage (1,000-volt generators would only require about half the size cables), yet there is more risk of breakdown, more loss through leakage, and more personal danger than by the lower voltage. We should be glad to give H. Jay any further particulars and information.
WEBSTER MICHELSON AND CO.,
Dudley. Electrical Engineers.

[96665.]—**Coal and Electricity.**—Anything like a satisfactory reply to this query would occupy far too great space. If H. Jay cares to write to me, I will be very pleased to look out the pros and cons. of the question for him.
Moffat. W. J. G. FORMAN, C.E.

[96665.]—**Coal and Electricity.**—The data are hardly sufficient for any definite reply to be given. Some kind of idea might be put forward; but being based upon such insufficient particulars, it could only be misleading. If H. Gay will advertise his address, I will put myself into communication with him, and go into the matter thoroughly.
PHILOS.

[96669.]—**Mercury's Mass.**—The mass of any planet without a satellite can be determined in terms of the sun's mass by means of the perturbations it produces on the orbits of other planets. The amount of these perturbations is always proportional to the disturbing force, and this again is proportional to the mass of the disturbing planet. In this manner the mass of Venus has been found to be about 1-400,000th of the sun's mass and that of Mercury about 1-5,000,000.
Llanrwst, North Wales. J. C. M.

[96669.]—**Mercury's Mass.**—Taking the mass of the earth at 100, that of mercury is 7.
B.Sc.

[96670.]—**Spring Motors.**—Purchase an old Morse train. These can be often seen on coster's barrows in the Farringdon-road. They may generally be depended on for even speed, and can be had for a few shillings.
ELECTRICIAN.

[96674.]—**Model Dynamo.**—To MR. BOTTONE.—Premising that a dynamo with H armature can be by no means called a "standard type dynamo," the following data will enable you to wind your castings so as to get 20 volts at 3,500 to 4,000 revs. per minute. Wind the armature with 5oz. No. 22 d.c.c., and the field-magnets with $2\frac{1}{4}$lb. wire of the same gauge connected up in shunt. (2) The best form of armature for accumulator charging is certainly a many-sectioned drum. The most convenient and the one giving the most satisfactory results in such small machines as you describe is a laminated tripolar.
S. BOTTONE.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

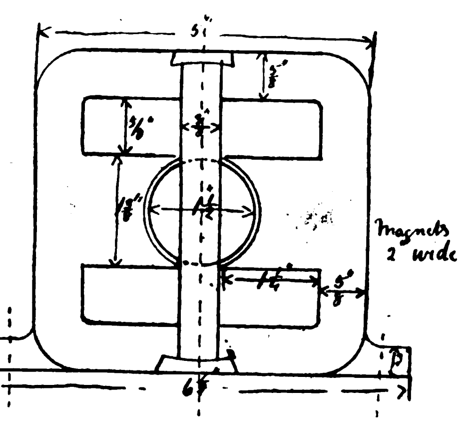
THE electrical energy required to produce a ton of calcium carbide is 4,260 kilowatt hours; or, in other words, a kilowatt will produce about $12\frac{1}{4}$lb. of the carbide in twenty-four hours.

QUERIES.

[96677.]—**Voltage.**—In magnetising a rod of iron, should be grateful to know what size copper-wire will be most convenient or most proper to use? Will the current from a dynamo do, or must cells be used? What would be the best dynamo to use, one giving a great amount of voltage or ampèreage? What is wanted is a high degree of magnetism in large iron rod.—Ivanhoe.

[96678.]—**Spark Coil.**—I have commenced to build a spark coil whose core is 11in. long, ⅞in. diameter, wound with two layers No. 18 wire, saturated with paraffin wax, and inclosed in ebonite tube ⅛in. thick. The secondary is of No. 36 silk-covered wire wound sectionally, each section being ⅛in. bare in thickness, so that when all wound there will be about 40 sections on tube. I am making the secondary slightly barrel-shaped, also leaving greater space at ends of coil between sections and tube than in middle. I have already wound and properly connected up nine sections (containing altogether 1lb. wire) at one end of coil; but on testing with current from eight bichromates (each exposing a negative surface 3in. by 4in.), the spark produced was barely $^1/_{32}$in. The condenser (already made) has 120 tinfoil sheets 6in. by 5in., but I did not put it in circuit when testing. Now what I want enlightenment about is this: Seeing that the secondary already wound is over one-fifth of what the whole will amount to, should I not now obtain a better spark than $^1/_{32}$in.? I may mention that there is no break in the nine sections wound, and that all is thoroughly insulated with paraffin-wax. But supposing that a better result cannot be expected at this stage, what spark (approximately) may I look for when all 40 sections are wound (when the total weight of wire will be about 6lb.) and condenser in circuit, using same battery power? What should be the ratio of increase in length of spark for each added section?—Wm. Hy. Bell.

[96679.]—**Dynamo.**—To Mr. Avery.—I am making one of your Lahmeyer dynamos as per sketch. Could I wind it to give an output of 10 volts at 10 amps. 100



watts either in compound, shunt, or series? If so, please give me size and quantity of wire. I want to keep carcase as small as possible. If any enlargement, please state. Would a ¼H.P. engine drive it with constant steam-pressure?—Dudley.

[96680.]—**Temperature.**—Would some reader kindly inform me of a cheap and effective means of reducing the temperature in a chamber 15ft. square by 8° or 10°?—N.

[96681.]—**Boilers Fitted with Projecting Studs.**—Can any correspondent kindly inform me in what respects Fletcher's method of using studs projecting from boilers differs from that formerly used by G. Wye Williams? Has either been applied to the bottoms of ovens or kitchen ranges to increase the heating power?—Stud.

[96682.]—**Nibbling Machine.**—Will someone give a drawing of a nibbling machine of 1H.P., and say how to drive it from an electric cable?—T. G. W.

[96683.]—**Cycle-Motors.**—Would "Monty" or "The Writer of the Articles" kindly tell me what he thinks of the "Endurance" tricycle-motor? I purchased a set of castings about eight months ago, and have not yet had time to start on them. They seem a good bit different to the one described in "E.M." The cylinder is 3 by 4, and is only supposed to be 1½H.P. How is this?—it is a bigger motor and less power. Would you suggest any alterations before I start? Also, by doing so, should I increase the power. Also, is their vaporiser all right, or would it be best to fit one as described in the articles? I should be very pleased for a reply, as I have heard no report on them or anyone's opinion, and don't want to waste my time and money on something which I should in the end be disappointed with, which a little tip at the beginning might have altered.—Lanky.

[96684.]—**Telescopes.**—I was much struck with Mr. Clarke's letter (No. 42784) *re* his corrector. I have myself been experimenting in this way lately; but hitherto without much success. Would some reader "in the know"—might I venture to ask our good friend "F.R.A.S."?—kindly comment on this method, and also say whether it would be possible to use smaller lenses than W. Clarke's, say 1in. or 2in. diameter, at a greater distance from o.g., supposing diameter of the latter to be 5in., and its focal length 72in.? What would have to be their distances from the o.g. for achromatism, and what the distance between them for correcting spherical aberration?—A Beginner.

[96685.]—**Motor-Cycles.**—Will "The Writer of the Articles" kindly say—(1) Would not hard gunmetal do equally as well as steel for the bushes of the connecting-rod? (2) Will cast-iron lathe change-wheels with uncut teeth answer instead of the cut gearing?—Motormad.

[96686.]—**Motor-Cycles.**—Will "The Writer of the Articles" or "Monty" please state the objections to injecting or rather pumping the petrol directly into the engine cylinder? Would this not do away with a great deal of the space and also weight now taken up with a carburettor?—Wm. F. Rigby.

[96687.]—**Black Straw-Hat Polish.**—Will any reader be kind enough to supply writer with particulars how to make black straw hat polish?—Milliner.

[96688.]—**Oil-Engine.**—I have an oil-engine, using common petroleum. The diameter of cylinder is 4in., length of stroke is 8in., and the power is said to be 1B.H.P. I would like to get an increase of power. "Monty," at p. 96 (96566) of your last issue, advises "trike" owners to use electric ignition, and the gain in power would be 25 per cent. Might I expect the same increase in my case if I were to substitute electric ignition for the lamp now used? And if, instead of using petroleum, I were to use petrol, would the power of my engine increase? If not, how is it that the motor-cycle now being described in the "E M." is 1¾H.P., the dimensions of cylinder being only 2⅝in. diam. by 3⅛in. stroke?—Bivalve.

[96689.]—**Cooling.**—Will some correspondent kindly inform me what the temperature of air would be when expanded from 360 to 33 atmospheres, and from a temperature of − 50° C., the air to do work in a cylinder during expansion?—F. P.

[96690.]—**Dynamo.**—I have the castings of a dynamo of the Lahmeyer type and I require 65 volts. Dimensions: Core of magnets 1⅞in. high, 3in. wide, 1¼in. long; armature diam. 2⅛in., 3½in. long. Would Mr. Bottone greatly oblige by informing me what quantity and size of wire (in mm.) I would require to wind the armature in coils, and how many ampères I may expect?—Sala.

[96691.]—**Acetylene Gas.**—I am desirous of illuminating my premises and shop with acetylene gas. All the price lists which I have from the different firms seem to speak very highly of it, not only with regard to the clean light for shops and for its brilliancy, but also the saving in expense, for the makers claim that the gas can be made for 2s. 6d. per 1,000ft., whereas the coal-gas in this town is 3s. 9d. per 1,000ft. As you can see, we have coal-gas in this town, but it is not satisfactory unless mantles are used, which soon seem to diminish in illuminating power, as well as requiring a lot of attention. I am rather dubious of trying the experiment, for the reason I cannot understand why acetylene is not in more general use than it seems to be if it has all the advantages claimed for it. Should you advise the use of acetylene where coal-gas is laid on in the town?—Percy Wadham, Newport, I. of W.

[96692.]—**Liquid Nitrogen.**—Suppose some liquid nitrogen were placed in a vessel, and sealed down so that it could not expand, its temperature being − 146° C. The temperature is now raised to, say, − 136° C. What would be the pressure exerted, as it would now be 10° above its critical temperature, and, therefore, must be in gaseous state?—Pressure.

[96693.]—**Colouring White Metal.**—I shall be much obliged if a reader would say which would be the best way to colour white metal sheet—red, black and blue, or yellow. Wanted to stand the weather and bear knocking about without losing colour. A way to colour without enamelling will oblige.—G. S. Wade.

[96694.]—**Circular Saw.**—Could any kind reader inform me the cheapest way to fix up a bit of machinery for a donkey to work to drive a circular saw at a high speed to cut deals.—R. T.

[96695.]—**Dipleidoscope.**—Is it possible to obtain true time with a dipleidoscope? I cannot undertake siderial observations, but should like to be able to get the time with some such instrument.—Tempus.

[96696.]—**Cycle-Motor—Spring Tempering.**—Will some kind reader of "ours" who have had experience in such matters explain to us what kind of motor is the best, and most light and compact for attaching to drive a safety bicycle? The power of motor need not be more than about $^1/_{20}$H.P. or so—i.e., sufficient to drive the machine on the level, and to assist one when pedalling uphill. Would it be practicable to fit up an electro-motor of that power to receive current from a small accumulator, the motor to work as a dynamo to charge same when machine is going downhill? Or would a small oil-motor be better? What about the heat given off by the latter? In what book can I get full particulars for tempering all kinds of steel springs—coil, conical, spiral springs, &c.?—Fiat Lux.

[96697.]—**Lime-Water.**—From what kind of lime is lime-water prepared for medical use? Is it from the comparatively pure, fat, upper white chalk-lime, or from the poorer mixed lime made from the grey chalk lime of the lower beds, known in London as grey chalk lime?—R. S.

[96698.]—**Scene Painting.**—Can anyone give me any information concerning the following queries? (1) What material to use for the painting of scenes for a small school cantata? (2) What colours, paints, &c., are used? (3) The name of any book containing directions, &c., as to mode of procedure?—T. Thomas.

[96699.]—**Purification of Well.**—The water which I use from my well I find to be slightly contaminated with some impure matter. The colour is slightly reddish, and the odour points to a small amount of nitrogenous matter. I cannot trace any connections with the sewerage, nor even with any surface water. I have been advised to place some charcoal in the well, or even a small amount of lime. Can anyone advise me what would be the effect of the use of this charcoal or lime? Would not the charcoal itself become putrid after a time? I would be pleased to have some advice on the subject.—Kitwell.

[96700.]—**Shaving.**—Why is it that a barber or nearly everyone who shaves himself warms the razor in hot water before shaving? Does it really cut better (everyone whom I have asked says it does), and, if so, for what reason? The native barbers of India and the East seldom use hot water, and they seem to shave all right.—Nix.

[96701.]—**Invisible Light.** — In this month's *Chambers' Journal* we read that a modification of the X-rays has been discovered by a Frenchman. His theory is that ordinary light is composed of visible as well as invisible rays. To produce these you merely cover up your light. If then you wish to discover anything hidden—in a box, for instance—you place a screen covered with sulphuret of zinc in front of the box. The object is then shadowed (?) on the screen. Have any other readers seen this, and have they tried it? Also, what is sulphuret of zinc?—Alpha.

[96702.]—**Glue.**—Could any reader tell me of anything you could mix with glue so as it will stand a gentle heat without going soft?—Chips.

[96703.]—**Cycle Chain.**—Can any of "ours" tell me how I can prevent a cracking noise in the chain of my cycle? If I take it off and wash it in paraffin, and wipe it quite dry, and put it on again, it stops; but after riding about 15 miles it wants lubricating, and then it starts making the noise again.—Welsh.

[96704.]—**Ivory Polish.**—Will any reader kindly give recipe and method of polishing ivory billiard balls?—W. T. G.

[96705.]—**Jupiter.**—On August 31 a spot passed the C.M. about 11.30 p.m., and again noticed some days afterwards. Will someone kindly work out the longitude, giving detail in full, according to system 1 or 2? Would "Chambers' Practical Astronomy" explain the working out, or any other handbook?—Novice.

[96706.]—**Cutting Up Slate.**—Can any reader give me any hints on cutting slate up? I have a milling-machine, and have tried to use a cutter with teeth; but it will not do. I have got a lot to cut, so should like to cut it quick. I have also got to enamel the slate, so should like to know how to do this? I am making an iron stove to bake it, as I was told to do. I was told that to get a fine, smooth gloss on the slate it has to be done by hand. Is this right? Any hint will greatly oblige.—Enamel.

[96707.]—**Bus Bars.**—I should like to know if anyone can tell me the rule to make bus bars for fuse-boards, or can I get a book on same—I mean bus bars for three-way boards? What should be the thickness, length, and width?—Enamel.

[96708.]—**To Mr. Bottone.**—Will you kindly tell me how one may obtain the D.Sc., or corresponding degree, at any of the Italian Universities, or tell me where I could get the information?—Chemist.

[96709.]—**Hovis Bread.**—Will some reader kindly tell me how Hovis bread is made? Is it easily mixed and nutritious?—G. Calver.

[96710.]—**Surface Tension.**—Can any reader give me help with the following problem? Calculate the work done on the film in blowing a soap-bubble from a diameter of 3cm. to one of 30cm., if its surface tension be 45 in C.G.S. units.—J. Bennett.

[96711.]—**Spiral Gear-Wheels.**—Can any reader tell me if spiral gear-wheels for gas-engines can be cut in an ordinary 9in. lathe? If not, how could it be done, and how many cutters would it need to do both wheels? Give rough sketch, please, if needed.—J. C.

[96712.]—**Lantern Slides.**—Can anyone give me some help in the choice of a hand-camera for snapshots to be used in the lantern? I want to take the pictures of the size suitable for the lantern, so as not to have to enlarge or reduce them, and my idea is to have the cheapest reliable camera capable of carrying, say, twelve plates. I believe the "Fram" is a very good camera, but it is far too expensive for my purse, and the specially-shaped films are a drawback. Are the Kodak films easily detached and developed, or must one expose the whole cartridge before commencing to develop any one picture? What are the objections to films as compared with plates for my purpose? Sometimes a reversal is found in a negative: for instance, the sun appears as a positive image. I presume this is from considerable over-exposure? Now, is it possible for our chemists to devise a plate which shall always give a reversal—i.e., a positive instead of a negative image? I believe this is already done in ferrotypes and other cheap photographs. Such a plate, when developed and fixed, could be put at once into the lantern, thus doing away with the trouble and expense of printing another plate. Wishing to use a lantern for perfecting sharp shadows of solid pieces of apparatus placed between it and the screen, I am disappointed in getting only a shadow with an indefinite outline. My lantern is an oil one. I was undecided as to whether to get an oil or a limelight one, although I favoured the former on account of its greater portability; but my choice was determined by the statement in the maker's catalogue that this lantern would give a parallel beam. If this is correct it would obviously be possible to converge the parallel rays to a point (by means of a lens) where they would cross and give as sharp a shadow as if the original source of light were a point. This does not "come off," however, and I cannot focus them so as to produce a point. I conclude, therefore, that the statement as to a "parallel" ray being producable should not have appeared in the catalogue. If I am wrong, perhaps some expert will tell me how to produce the sharp shadows I desire without a limelight.—A. Tester.

[96713.]—**Test for Arsenic.**—Can any reader of the "E. M." give me the information how to discover the presence of arsenic in wall paper?—Desmond.

[96714.]—**Electrophorus for Wireless Telegraphy.**—I wish to make a few experiments in wireless telegraphy, but, having no machine or coil capable of producing a suitable spark, I am looking about for the cheapest substitute. Would a common glass plate electrophorous meet the case if used with the three-ball transmitter previously described? If so, what sized plate should be obtained? I do not require to ring a bell, but merely to produce a deflection in the needle of a delicate galvanometer.—Wireless.

[96715.]—**Quadruple Telephony.**—I understand that one of the American Telephone Co.'s have offered a prize for a system of quadruple telephony. Have you any particulars of this competition, please, and does it imply that four persons are supposed to be actually speaking at one time, or only two persons speaking and two listening? If the latter, I think I have struck the oil?—Wireless.

[96716.]—**Solenoid.**—Will Mr. Bottone or any other

kind reader give me advice? I have a bar magnet of soft iron, ⅝in. diameter, 1ft. long, and the same, when excited by three bichromate cells, will lift 12lb. I am thinking of turning it into a solenoid by drilling a ⅜in. hole through centre of core. What fraction of lifting power will magnet now have of what it had before (supposing the weight to be raised is attached to a soft iron rod 1ft. in length, and thick enough to fit nicely into bore)? And to what distance would the rod travel up the bore when no weight were attached?—C. V. E.

[96717.]—**Shaving Cream.**—Can anyone give a good recipe for shaving paste or cream?—H. H.

[96718.]—**Bonetti-Wimshurst.**—Where can I find a detailed description of this machine? Is it superior to the ordinary Wimshurst for X-ray work?—P. H. CULEIS.

[96719.]—**Gauging Tanks.**—I wish to gauge contents for each inch in depth of flat-ended cylindrical boiler tanks, lying horizontal. A formula or graphic method for any size is desired, but 28ft. by 7ft. might be used as illustration.—CHEMICAL.

[96720.]—**Hotel Problem.**—During a month of 31 days, an hotel averages 34 visitors daily, who pay per week—on the average—three guineas each *en pension*, which sum shows a weekly average profit per visitor of 17s. 2d. For three weeks of the month, two of these visitors pay £2 3s. 4d. per week each. Are they a source of gain or loss, and how much?—P. E.

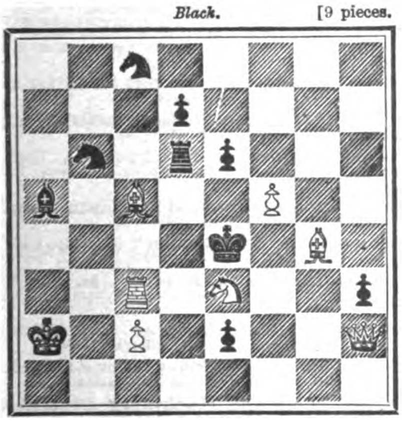
[96721.]—**Launch.**—I wish to construct a small launch 18ft. or 20ft. long, to be driven by gasoline engine. Can any reader give me a few pointers as to dimensions and model of boat, method of construction, &c.? Also, could engine be easily made by amateur? A rough sketch would be appreciated.—J. H. WINFIELD, Nova Scotia.

CHESS.

All communications for this column to be addressed to The Chess Editor, at the Office, 332, Strand.

PROBLEM No. 1693.—By C. PLANCK.

Black. [9 pieces.



White. [8 pieces.

White to play and mate in two moves.

(Solutions should reach us not later than Oct. 2.)

Solution of PROBLEM No. 1691.—By C. A. GILBERG.

Key-move, R-Q 4.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1691.—Correct solution has been received from Rev. Dr. Quilter, A. Tupman, W. F. Webb ("A pretty little problem") G. S. Hardy, Quizco, T. Clarke, J. E. Gore ("Pretty, but easy"), Hampstead Heathen, Richard Inwards, Whin Hurst, Geo. Christie, G. W. M. ("Key-move will suffice, and, of course, solve from the diagram"), E. C. Weatherley, E. Lobell, jun.

IT is believed by oil experts that West Virginia, in America, is underlaid by a real sea of petroleum. The output of one kind of oil last year amounted to over 18,000,000 barrels.

A MOVEMENT is said to be on foot in Ireland to develop the Queen's County anthracite mines, in so far as providing a railway connection between the pits and the main line of the Great Southern and Western Railway Company. Efforts are being made to induce the Chief Secretary to recommend the Treasury to grant a sufficient sum to make the line to Portarlington.

A FIVE-INCH Brown segmental wire gun, the first completed, has successively passed the official tests of the United States Government at Birdsborough. The gun was required to give a muzzle velocity of not less than 2,600ft. per second, 295 shots being fired with a 55lb. projectile and smokeless powder, developing a mean pressure not exceeding 40,000lb. per square inch. Following this, five shots were to be fired with powder pressures varying from 45,000lb. to 50 000lb. per square inch. The peculiarity of the gun lies in the fact that the circumferential strength is obtained practically entirely from the wire winding, the barrel being built up of staves of a hard steel, round which the wire is wrapped. These staves give the necessary longitudinal strength of the gun, but obviously do not add to its strength against bursting.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Sept. 20, and unacknowledged elsewhere:—

F. E. A.—Lucio.—J. S. Z.—Bunsen.—W. H. Bland.—G. E. O.—Improver.—R. A. Kennedy.—S. R. Bottone.—W. J. G. F.—L. Panton.—F. Baird.—Monty.—C. P.—T. E. Espin.—Pierre.—Raymond.—G. S. Hardy.—J. Bennett.

H. JARVIS.—Thanks; no. Very full up just now.

H. H., Croydon.—Too far back; besides, we are really too full just now to discuss illustrations in other periodicals.

R. G.—Please see some recent letters on the subject, and the full directions given for making reflecting telescopes in recent volumes. Do you intend to grind the speculum yourself, or are you going to purchase that and mount it? Anyway, you will find full directions and many hints in, say, the last six volumes.

A. R. CRANE.—Do you mean 3-4H.P., or an engine with a 3-4in. cylinder?

JOHN THOMAS.—1. It is usual to serve a term of apprenticeship in a shop where such work is done. 2. Maxton's "Engineering Drawing," published by Crosby Lockwood and Son, is a good work, and Campin's "Mechanical Engineering," from same publishers.

WORRIED.—The remedy for blackheads, frequently given, is to wash the parts with warm water and soap, and squeeze them out; but it has also been recommended to use paraffin oil after the washing, kneading the parts well to work them out. You will find several replies on the subject in the back volumes.

IGNORANCE, Ontario.—"Guide to the Social Marine Board Examination," G. Philip and Son, Fleet-street, London, 1s. 6d., will help, and ask them to send their catalogue. Norie's "Epitome of Navigation," Norie and Wilson, Tower-hill, London, 16s. Cannot answer the other questions; but a little personal inquiry amongst seafaring men will give you some useful hints.

NIX, Jeypore.—Yes, quite true. The warmth softens the hair, and also expands the microscopical saw-like edge of the blade. But there is not much in the notion. Probably it runs easily over the surface when warm. As you live so far away, the query is inserted.

ALPHA.—There are several works of the kind, giving "restorations" of the prehistoric animals and fancied reproductions of the conditions in which they lived. You could see many at the British Museum Library.

C. A. NAYLOR.—The aneroid barometer is described in many of the textbooks. The name means "without moisture." It consists of a box or case of metal so flexible as to be acted on by variations in the pressure of the atmosphere when the air is exhausted from its interior.

A. S. GEORGE.—Try Lancaster and Son, Colemore-row, Birmingham.

G. S.—Such questions should be put to a patent agent, giving him all particulars. His charge will depend on the time he has to expend in searching. Whether it is patented in this country or not is of little interest to our readers.

P. H. CULEIS.—As to superiority, you could find opinions of correspondents in back volumes; but as a detailed description is required, query is inserted.

J. B. T.—The cost will depend on the quantities of the materials that are purchased at a time; but have you not made some mistake? For what purpose are such preparations required?

JUPITER.—Something else to do besides discussing old wives' tales about cauls!

W. MATTHEWS.—All such inks harden. Thin it down with a few drops of methylated spirit or benzoline.

METEOR.—Mr. Ivo. F. H. C. Gregg, in a letter received too late and too long for publication, thinks he saw the meteor referred to by Mr. Lynn (letter 42780, p. 89) at Great Malvern at 9h. 10m. G.T., but from R.A. 16h. 30m. N. Dec. 3 to R.A. 15h. 40m. N. Dec. 8, or in quite the opposite direction to that in which the meteor seen at Blackheath went.

JOHN WALKER.—The debility is due to quite other and natural causes. If you are single and leading a regular life, the rest is quite natural. Get Dr. Allinson's "Pamphlets for Young Men" from their author at 4, Spanish-place, Manchester-square. They only cost a few pence, and contain sensible advice. As to diet, &c., read his articles weekly in the *Weekly Times and Echo.*

IN TYPE.—Martin Luther Rouse.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

s Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for ess than a quarter-page; per inch single column—

1	6	13	26	52 insertions.
7s. 0d. ..	6s. 6d. ..	6s. 0d. ..	5s. 6d. ..	5s. 0d. each.

Per Column.—

1	6	13	26	52 insertions.
£3 0s. ..	£2 15s. ..	£2 10s. ..	£2 5s. ..	£2 0s. each.

	1	6	13	26	52 insertions.
	£ s.	£ s.	£ s.	£ s.	£ s.
Per Page....	8 8 ..	7 0 ..	6 0 ..	5 5 ..	5 0 each.
Half-page ..	4 10 ..	3 15 ..	3 10 ..	3 0 ..	2 10 ,,
Quarter-page	2 10 ..	2 5 ..	2 0 ..	1 15 ..	1 10 ,,

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "———," care of the ENGLISH MECHANIC Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

What Offers for about 350 Back Nuumbers "**English** MECHANIC, or exchange?—W. UPTON, Bridge-street, Banbury.

3H.P. Tangye's **Gas-Engine** and 50-volt, 15-amp. DYNAMO; can be seen running; wanted £30, or exchange smaller Gas-engine or Steam Boiler, or offers.—Particulars stamp.—CHAS. FORD, Electrician, Stalybridge.

Water-Motor, Phonograph Castings, Motor Castings, Gem Air-Gun, Magneto Machine, Organette, 50 tunes, for Bicycle or anything useful.—J. MORSE, Magpie-road, Norwich.

Dynamo, 20 volts, 5 amps., drum; 4in. ring Phonograph Motor, for cash or exchange.—Below.

Phonograph Top, complete less diaphragm; also Weston Ammeter, 0 to 15. Exchange. — DUFFILL, High-street, Sandgate.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of Screws, Bolts, and NUTS for model work, drawn to actual size, sent on receipt of stamp. —MORRIS COHEN, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—MORRIS COHEN, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—CLEGG, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—JARRATT, Queen-street, Leicester

Carving. — Brass, Iron, Burnt Wood, Bamboo, Leather, Fretwork, and Picture Framing. Catalogue free.—HARGERS, Settle, Yorks.

Inventions Protected, £3 inclusive. Designs registered, 30s.—BROMHEAD and Co., Registered Patent Agents, 33, Cannon street, London. Established 25 years. Send for list.

Sidereal Time Indicator, invaluable to all users of equatorials, with complete directions, 21s. post free.—Below.

Astro-Photographic Apparatus, does really good work, 15s. post free.—HORNE and THORNTHWAITE, 416, Strand, London.

Books.—All out-of-print books speedily procured, any subject. State wants.—BAKER'S GREAT BOOKSHOP, Birmingham.

50,000 Choicest Microscopical Objects.— Bargains. Catalogues free. Microscopes, cabinets. Collections purchased.—SUTER, 10, Highweek-road, Tottenham.

Rubber Outer Covers, 8s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—PEMBERTON.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—PEMBERTON.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—PEMBERTON.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—PEMBERTON and Co , 1, Cardwell-place, Blackburn.

Acetylene. — Send for particulars of the patent "Incanto" Generators, Purifiers, Burners, Carbide, &c.—THORN and HODDLE, 1, Tothill-street, Westminster. Works, Harris-street, Camberwell.

Inventions Protected and Sold. Inventors assisted. Advice free.—ELT and Co., 43 Southampton-buildings, Holborn, London.

Practical Milling in the Lathe has been reduced to its simplest possible form by our Simplicity Milling Attachment. Send stamp for list to—SMART and Co., Erith, Kent.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—BUTLER BROS., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—BUTLER.

Have You Sent Yet

For Our "Twenty-five Best Books"?

They are Good Value for the Money.

They are Now Ready, and we shall Not REPRINT.

For Full Particulars see Illustrated Advertisement on another page.

Best Assortment of High-class Popular Literature ever obtained at the price.

A Splendid Present to a Friend, or a Village Club, or Working Men's Institute.

Guaranteed to give Satisfaction. Well printed, well selected, well bound. Price, all complete, only 30s.

Send Cheque or P.O.O. for 30s. at once to the Publisher of the ENGLISH MECHANIC, 332, Strand, W.C.

Delivered in London Free. Country orders sent carefully packed, by rail, carriage forward. Please write address plainly.

Send at Once to Save Disappointment. Price for the set complete, in oak bookcase, 30s. Obtainable only at the Office of the ENGLISH MECHANIC, 332, Strand, W.C.

Simplex Typewriter, 14s. 6d., delivered. Thousands in use. Illustrated particulars free.—ATKINSON and Co., Harehills-avenue, Leeds.

Automatic Machines of every kind, including Musical Polyphons, new game machines, and novelties for public bars and restaurants. Also money-making machines for seaside resorts. Illustrated catalogue free.—Address INTERCHANGEABLE AUTOMATIC MACHINE Co., Ltd., 317, Upper-street, London, N.

Wheel-Cutting.—Spur, bevel, mitre, or spiral gear, in all metals, to any pitch.—MOTOGEAR, below.

Differential and Spur Gearing as illustrated in "E. M." Motor tricycles. Special prices.—MOTOGEAR, below.

Accurate Screwcutting and Fine Turning a speciality.—THE MOTOGEAR ENGINEERING Co , 78, Queen Victoria street, E.C.

"Gem" Gas-Engines.—Still simplest and best for small powers.—MOTOGEAR Co., below.

"Gem" Gas-Engine Castings. — Easiest to make up.—MOTOGEAR ENGINEERING Co., 78, Queen Victoria-street, London.

"Gem" Oil-Engines.—New designs for launches and vehicles, &c.—MOTOGEAR Co., above.

Paraffin Wickless Stoves burn without smoke or smell, safe and reliable, very useful in household.—Below.

Paraffin Wickless Stoves, powerful and easily managed, splendid thing for yachting, boating, camping-out.— Below.

Paraffin Blowlamps for Plumbers, Painters, Brazing, and Ignition Tubes. Illustrated lists, stamp.—HICKS, Tool Merchant, Maldon, Essex.

Stereoscopic Views, 1s. doz., list 4,000. Sample 1d. stamp.—PUMPHREY, Stanhope-street, Birmingham.

Cycle Stocks and Dies, special fine threads, in cases complete, with taps and wrench.—Below.

Cycle-Spoke Screw-Plate and Gauge Combined, cuts seven Abingdon sizes, 4s. 9d. post free.—Below.

Hand and Breast Drills, Vices, Hack Saws, &c. Illustrated lists, stamp.—HICKS, Tool Merchant, Maldon, Essex.

Brass and Gunmetal Castings of finest quality. Prices on application.—DANIEL YOUNG, Witney, Oxfordshire.

Engineers, Cycle Makers, all Metal Trades—send for particulars of our foot-power Emery Grinders.—Below. 25s.

Far Superior to the Grindstone for Twist Drills, Chisels, Slide rest Tools, Hand-turning Tools, &c.

Illustrated Particulars Post Free. Send for one on three days' trial.—W. PARRY, 158, High Holborn, London.

Foreign Hardwoods for Amateur Turning and Fretwork.—DANIEL, 242, Bethnal Green-road, London. List one stamp.

Motor-Car Engines to any specifications from ½ to 6B.H.P.—H. JONES.

Gas-Engines, Otto cycle, horizontal, ½B.H.P., £12. 1½B.H.P., £20. Descriptive list stamp.—H. JONES.

Oil-Engines, horizontal, ½B.H.P., £13 10s.; 1½B.H.P., £22; extremely simple.—H. JONES.

Dynamos, vertical drum, 4-lights, £3 10s.; 6-lights, £5; 8-lights, £6 10s.; 10-lights, £8.—H. JONES.

Dynamos from 30s. Lighting, plating, storing, &c. —H. JONES, 14, High-street, Lambeth, S.E.

Cheapest Printing!!!—100 Billheads, Business Cards, Memorandums, &c., 1s. 3d ; 1,000, 5s. 6d. Satisfaction guaranteed.—GANNON, Printer, Chelmsford.

Boards (Planed).—Cutting to lengths and widths a specialty, quotations free. Send sizes wanted.—BURTT, Gloucester.

Organ Bellows, Soundboards, &c., for Sale, cheap. SCORR, 6, Cowey-place, Penrith.

Booker Brothers' Engines and Motors, oil or gas, ½H P. upwards, also castings.—Tyrrell-road, East Dulwich.

Astronomical Telescopes, Second-hand. — CLARKSON and Co., 28, Bartlett's buildings, Holborn-circus, Optical Dealers and Manufacturers.

Astronomical Telescope, 4in. equatorial, by Cooke, and clock, with eyepieces.—CLARKSON and Co.

Astronomical Telescope, 4in. altazimuth, by Cooke and Sons, complete, £30.

Astronomical Telescope, 4in. altazimuth, by Wray, complete, £30.—CLARKSON and Co.

Astronomical Telescope, 4in. altazimuth, by Troughton and Simms, £25.—CLARKSON and Co.

Astronomical Reflector, 8½in., Browning, with slow motions, £35.—CLARKSON and Co.

Astronomical Reflectors, 5¼ Wood, complete, £9 10s. 6½in. Browning, £20. 6½in. Calver, £17 10s.—CLARKSON and Co.

Astronomical Telescopes for students. 3in. Newton and Co., £4 10s. 3in. Solomon, slow motions, £6 10s.— CLARKSON and Co.

Astronomical Telescope, 3½in. Wray, with garden stand, finder, and three eyepieces, £18 10s.—CLARKSON and Co.

Astronomer's Outfit.—6in. Telescope and Observatory, £35 complete.—CLARKSON and Co., 28, Bartlett's-buildings, Holborn-circus.

Astronomer's Outfit, observatory and equatorial, and spectroscope, 6in. Calver, Horne and Thornthwaite's equatorial, £35.—CLARKSON.

Astronomer's Outfit, bargain to a student, £35 complete, or observatory separately for £10.—CLARKSON and Co.

Bargain.—Magnificent Model Vertical Engine, tubular boiler, glass gauge, whistle, double action, slide-valve cylinder, bronzed stand, exhibition model, silver-plated, high-speed, and perfect. Worth 42s., accept 12s. 6d. free. Photograph 1d.— MANAGER, Marshgate Chemical Works, Stratford.

Bench Lathe, 12s. 6d. Photo. and List 6d. Lathe Catalogue, 6d.—STIFFIN, South Hackney, London.

Foot Lathe, 25s. Photo. and List, 6d. Lathe Catalogue, 6d.—STIFFIN, South Hackney, London.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, SEPTEMBER 29, 1899.

MOTOR CYCLES.—XIX.

FIG. 108 shows the shape of the two main tubes of the quadricycle attachment. They are made from 1¼in. by 18 gauge weldless steel tube, and should both be carefully bent to the same shape. Avoid denting the tube, for, besides spoiling the appearance, the strength is reduced. At their rear ends a mild steel forging, of the shape and dimensions given in Fig. 108, is brazed. It is by means of this forging that the tubes are bolted to the lugs on the bridge-tube. The part of Fig. 109 marked X is to be turned a good fit to the interior of the tube. Note that the forging is bored out;—this is done not only for the saving in weight, but also to increase the strength of the joint. If left solid, the vibrations of the tube will be suddenly checked, causing the metal to crystallise around the end of the solid lug, and become brittle and very liable to snap. The lugs for the bridge, by means of which the side tubes are clipped to the down tube of the tricycle, are shown in Fig. 110. They are of malleable cast iron, and require no special remarks. They are to be brazed to the side tubes as shown in Fig. 107, their centres being 33in. from the centres of the eyes in the lugs at rear end of tubes. Before brazing them in position put the tricycle into position, having previously removed the front wheel. Now fasten the clip, Fig. 111, on to the bottom tube of tricycle, and proceed to get the 1¼in. sockets of clip in line with the side lugs. At the same time, the lengths of the two pieces of 1¼in. tubing can be determined. When the two lugs, Fig. 110, are correctly adjusted, braze them securely in position. At the same heat it would be as well if the 1¼in. tubes were brazed in, too. The bridge clip (Fig. 111) is also of malleable cast iron. I have shown it with the caps bolted in position by two ⅜in. stud-bolts; but of course it is a separate piece. I give a plan of the cap in Fig. 112 to show shape and size of the lugs for bolts. In machining this casting, I should first face the joint between main casting and cap; then having drilled and tapped the holes for the screws, bolt the two parts together with a strip of 1/16in. sheet brass between them on each side, and bore out the central hole 1¼in. diameter. The brass strips are interposed, to allow of the clip closing down tightly on the tube when in use. The two sockets for 1¼in. tubes should be carefully bored to the correct angles, taking care to make them both the same. At the extreme front end of the side tubes is a cross-tube, also 1¼in. diameter by 18 B.W.G. This is brazed to the side-tubes by means of a tee-lug at each end. If preferred, the sockets can be formed at the ends of the cross-tube from the tube itself, as is done in the case of the stem-tubes of cycle handle-bars. But it will require to be well done, and in the case of an amateur I should advise malleable cast iron tee-sockets being used.

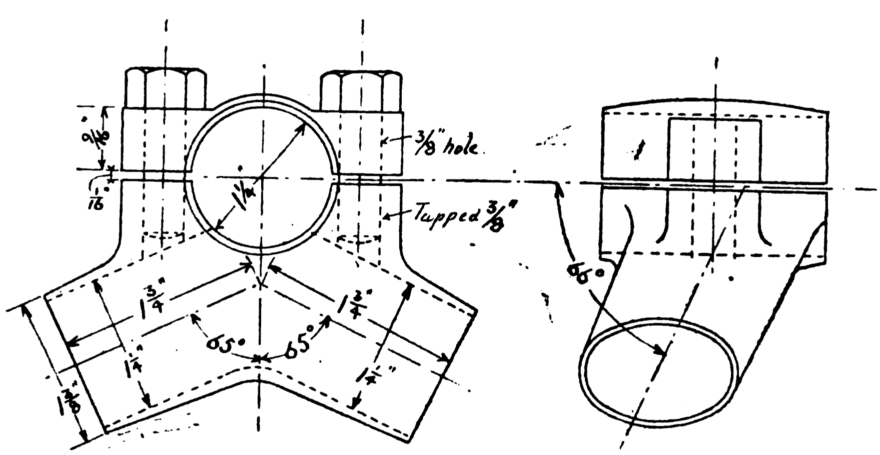

FIG. 111.

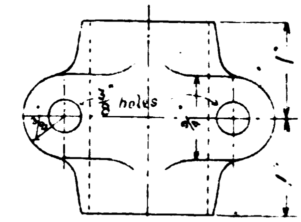

FIG. 112.

The front axle is made from steel tubing of the same diameter and gauge as the side tubes, the exact length being 28½in. At each end of the axle a lug, of the dimensions given in Fig. 113, is to be brazed. These lugs take the steering pivots, and are malleable iron castings; forged steel would be better, in which case the 5/16in. rib would be omitted. In machining these lugs the utmost care must be taken to insure the centre line of the two screwed holes being truly at right angles to the bore of the 1¼in. socket. See also that those screwed holes are dead in line

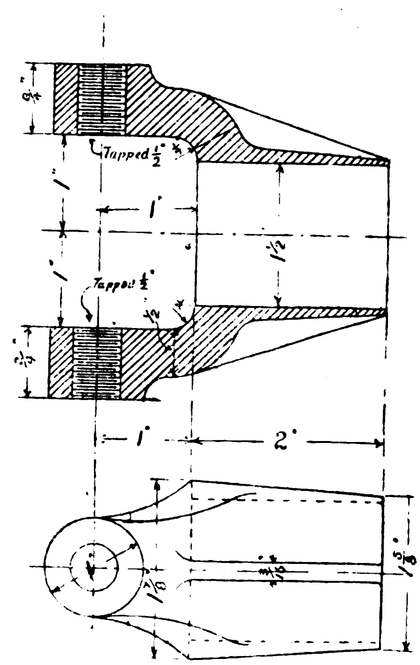

FIG. 113.

with each other. When brazing them to the axle tube, make sure that they are both upright, otherwise the steering will be thrown out. The centres of the steering pivots should be, when brazed up, *exactly* 30½in. apart. We will assume the springs to have been procured. To hold them to the axle and the side tubes, mild steel clips, as Fig. 114, will be used. Of these, eight will be required; the bow will embrace the axle (or side tubes),

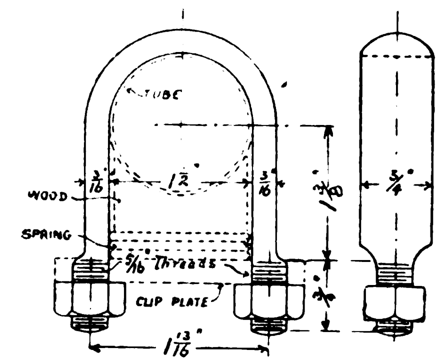

FIG. 114.

the spring being held by mild steel plates, ¼in. thick by ⅞in. wide, through the ends of which holes are drilled to take the clips. Wood packing must be placed between the springs and the tubes, the wood being hollowed out to fit each. These clip-plates and wood-packing are shown dotted in Fig. 114. The clips should be spaced 2in. apart, centre to centre, along the tubes.

The method of finding the Sidereal Time at Local Mean Noon at any other station is described on p. 454 of Vol. LXVIII.

The Sun's disc is still blank, and void of spots.

The zodiacal light may still be looked for in the east before sunrise.

Mercury

is too close to the Sun to be visible at the beginning of October, but souths after noon after the 4th, and becomes in that sense an evening star. He is, however, unfavourably situated for the observer throughout the month. His angular diameter increases almost insensibly from 4·8″ on the 1st to 5·2″ by the 31st.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	12 26·1	1 22·1	11 52·5 a.m.
6	13 3·7	5 58·1	0 4·0 p.m.
11	13 34·0	9 35·8	0 14·6 ,,

26	15 2·8	18 46·5	0 44·1 ,,
31	15 32·2	21 7·1	0 53·7 ,,

Starting thus from a point in Virgo a little below a line joining γ and η in that Constellation, Mercury will traverse the rest of it, and be found at the end of the month in the eastern confines of Libra. On the 9th he will pass about 2½° north of Spica Virginis, and somewhat less to the south of α Libræ on the 23rd. He will be in conjunction with Venus at 11 a.m. on the 10th, only 43′ south of her, and with Jupiter at 4 p.m. on 25th, 2° 20′ to the south of the great planet.

Venus,

in the sense of Southing after the sun, is an evening star throughout the month, but she is much too close to him for ordinary observation with the telescope. As she has so recently passed superior conjunction, her figure is to all intents and purposes circular, and her uninteresting little disc only increases from 9 8″ on the first to 10″ at the end of October—of course, wholly insensibly.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	12 46·5	3 40·7	0 6·4 p.m.

26	14 44·2	15 25·6	0 25·6 ,,
31	15 9·0	17 24·0	0 30·6 ,,

Like Mercury, Venus will thus travel from Virgo into Libra. At 6 p.m. on the 26th she will be in conjunction with α Libræ, and only 6′ north of that star. She will, however, have set some time previously in these latitudes. She will further be in conjunction (also below our horizon) with Jupiter at 1h. a.m. on the 30th (33′ south of him). Her conjunction with Mercury on the 10th has been referred to under the heading of that planet, above.

Mars, Jupiter, Saturn, Uranus, and Neptune

are one and all, for the observer's purpose, invisible; but the minor planet **Vesta** comes into opposition on the 14th, and may just possibly be picked up with the naked eye as a faint little star on the moonless nights at the beginning and end of the month.

Day of Month.	Right Ascension	Declination South.	Souths.

31	1 20·5	3 39 0	10 40·5 ,,

Whence it will be seen that Vesta is travelling backwards through a perfectly blank region in Cetus.

Shooting Stars

are becoming somewhat more plentiful, slight, though marked, displays being predicted for the nights of the 2nd, 4th, 8th to 14th, 20th, and 29th. The principal shower, however, of the month—that of the so-called Orionids, from the position of their radiant to the east of γ Orionis —will occur on the night of the 18th—unfortu-

nately, that of the Full Moon. Watch should, however, be kept after the constellation rises.

* Early morning of the 2nd.

The method of finding the Greenwich Mean Time of Southing of either of the stars in the above list on any other night in October, as also that of determining the local instant of its transit over the meridian of any other station, will be found on p. 456 of Vol. XVIII. It must, however, be noted, as there stated, that the rules given are not rigidly accurate when applied to Polaris, nor, in fact, to any close circumpolar star, though in practice they will doubtless be found abundantly so for the regulation of any ordinary clock or watch.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—IV.

METEOROLOGISTS have always been attracted by the search for what may be called the smaller pulsations in the atmosphere, and recognising that an ordinary barometer does not respond to minute variations in pressure, instruments which have a very open scale, or which are very sensitive, are always being invented. There are numerous ways of rendering a barometer more sensitive, and, although some of them have been in vogue during many years, the early models still find favour with modern inventors. Only in very exceptional circumstances can the mercury in an ordinary barometer be seen in motion, the most familiar of these occasions, perhaps, being when the mercurial column oscillates in the peculiar manner commonly known as "pumping," and what is required is to make these and other similar movements easily recognisable. Numerous causes are by some authorities considered to be at work pressing on a barometer, but so sluggish is the ordinary mercurial column that it is not prompted to movement by these minute aërial pulsations, and before they can be seen, it is necessary therefore to make the scale of the barometer a very open one. Thus some meteorologists say that certain electrical forces in the atmosphere will at times produce strange oscillations in a barometer having a very open scale; while other effects are ascribed to the changes which occur from time to time in the tension of the aqueous vapour in the air, and it becomes of interest to use instruments which will collect observations with which these and similar speculations may be compared.

Most of these sensitive barometers call for some special construction or modification of their tube, and there are commonly other details which can only be executed by expert mechanicians, but since they often introduce the student of the weather to new fields of research, they are always instructive and of permanent interest. Similarly to other human interests, there are periods when certain methods of meteorological procedure are more in vogue than at others, and in recent years there has not been such activity in the matter of inventing sensitive barometers as was the case many years ago. Probably the most prolific time for the construction of barometers with an extended scale was during the years almost immediately following that in which the barometer was invented, and for a long time the sole desire seemed to be to make instruments that should increase the movements of the mercurial column. The barometer was invented in the year 1643, and as early as 1665, for instance, Hooke had designed the wheel or dial barometer, an instrument which is still the most favourite method of increasing the size of the barometer scale. Moreover, since the wheel barometer lends itself so readily to ornamentation, it is probable that, despite certain faults, it will continue to maintain its popularity.

A novel design in sensitive barometers there is in which the mercury as it rises and falls passes through a wide range, the instrument depending for the details of its structure on the fact that glass is lighter than mercury. An ordinary barometer tube is filled in the usual way with mercury, and into it is plunged a small glass rod which has previously been attached to the bottom of a glass vessel, which subsequently acts as a cistern. While the glass rod is being plunged into the mercury the tube is held upside down, but it is inverted as soon as the bottom of the cistern fits tight against its open end, a piece of cork preventing the mercury from running out. As soon as the tube is inverted the cork is withdrawn and a little mercury flows from the tube into the cistern, and an ordinary barometric column is produced. The peculiarity of this instrument, however, consists in the fact that the cistern is not fixed to the tube in the ordinary way, but is left suspended in what at first seems an impossible manner. The glass rod within the tube is, however, much lighter than the mercury it displaced when it was thrust into it, and has accordingly a considerable buoyancy which is sufficient to sustain the cistern and prevent it from falling down. If now there comes a decrease in the atmospheric pressure acting on the surface of the mercury in the cistern, a certain quantity of mercury flows out of the tube into the cistern, and making the latter heavier would depress it, and this has the effect of lowering the barometric column still more. On the other hand, supposing there is an increase in pressure, more mercury is forced up the tube, so that the glass rod gains an added buoyancy, and pulling the cistern upwards adds to the rise in the barometric column. The effects of this buoyancy therefore, added to those of the atmospheric pressure, have the effect of greatly increasing the range of the barometer oscillations, the amount of the increase depending, of course, upon the manner in which the details of the instrument are arranged. For ingenuity of design this sensitive barometer may safely be accorded a high place among its fellow instruments.

A very popular way of increasing the motion of the barometric column is found by adding to the ordinary tube supplementary tubes containing fluids of a less specific gravity than mercury. Very early in the history of barometers this was a favourite device, and naturally almost the first fluid to be thus placed on the top of the mercury was water; and with careful management this arrangement has the effect of greatly multiplying the amplitude of the oscillations. But from the surface of water vapour is continually escaping, and the tension or pressure of this evaporated moisture presses upon the surface of the column and reduces its movements. It is also difficult to exclude air from these supplementary tubes, and some experimenters have therefore introduced tartar-emetic into the water with the object of driving the air from it. As regards the evaporation of moisture from the column of water, this has been diminished by covering its upper surface with oil.

These added tubes, however, give a very unwieldy appearance to the barometer, which, even in its more common form, proves often of an inconvenient length, and, although they are very sensitive to atmospheric changes, they require rather more house-room than most people can afford. This is still more the case when an ordinary siphon barometer is selected for carrying these supplementary tubes. These barometers have been supplied with tubes extending both from their longer and shorter limbs, and in some instances a mixture of water and aquafortis has been used as the fluid with which to fill them. In a former article it was pointed out that when a barometer is not hung truly vertical the mercury runs higher up the tube, and exaggerates the movements of the column; and it is not surprising, therefore, that barometers have been made with the upper portion of their tubes bent considerably out of the vertical. By this simple device the scale of a barometer may be very much extended; but when this form of structure is applied to tubes filled with water and certain oils, there is a drag put on the movements of the column, and the records are not, therefore, always trustworthy. The supplementary tubes mentioned above have, as might be supposed, been thus bent diagonally, some very curious-looking instruments being the result. They, however, are constructed on right principles, and it is to be wished that they could be made in the light of modern knowledge, for there are reasons for supposing that records obtained by some such instruments as these would help to explain many atmospheric phenomena which are at present but little understood.

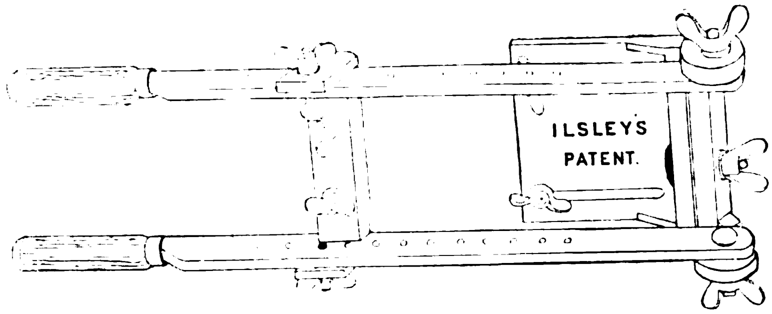
It is said by those who have watched some of these very sensitive barometers very closely that they may be seen moving very rapidly during thunderstorms, and that they oscillate considerably during each flash of lightning. Others again have stated that they have detected curious pulsations, which appear to accompany changes in the tension of the vapour in the air, and since it seems probable that discharges of atmospheric electricity play an active part in condensing vapour out of the air, a line of research is suggested which might lead to interesting results. As each atom of vapour rises from land and water it carries with it a tiny charge of electricity, and it is by these minute globules of moisture that the vigour of a thunderstorm is built up. It has also been conjectured that under certain conditions these drops of moisture are kept suspended because of the repelling action which they exert one upon the other, and it is when something occurs to lower the potential of their charge of electricity that they run together and fall as rain. That something of this kind may occur is evidenced by the heavy showers which so often follow brilliant flashes of lighning. When these discharges of vapour are very great the ordinary barometer responds to the accompanying changes in atmospheric pressure, these changes being best shown on the curves obtained from self-recording instruments. There are, however, all those smaller changes in pressure which occur during thunderstorms, and it is these of which it is so desirable to secure a record; and there are certain types of sensitive barometer sometimes called variometers which are well adapted for registering them.

Now the action of a barometer is not interfered with when its tube is twisted in a spiral, and there are many suggestions as to the best way of managing this alteration in structure. In some of these barometers it is the upper portion of the tube which is thus changed in shape, and in others it is the lower portion which is thus modified; while in other types, it is the mid-way portion of the tube which is selected for treatment. A siphon barometer may thus have the tube which connects the two legs or limbs arranged spirally, the short leg being left open in the usual way. In order that the movements of the mercury may be enlarged, the spiral portion of the tube needs to be of a smaller diameter than the two branching tubes, the spiral being arranged horizontally. The dimensions of one such barometer are so arranged that the spiral tube is 2 millimètres and the two branches 6 millimètres in diameter, this construction of the spiral resulting in a very large increase in the motions of the mercury. In order that these oscillations may be the better seen, a speck of air or a drop of sulphuric acid is introduced into the mercury, and this, like the bubble in a spirit-level, clearly shows any changes that may be taking place, and it is said that when

this speck is examined with a magnifying glass, it is seen to be in constant motion. Supposing the spiral were so arranged that the diameter of its tube were two millims and that of the two limbs of the siphon 20 millims, the motion of the barometric column would be increased one hundred times, and, indeed, there is no limit to the degree of sensibility to be gained by constructing a barometer on these lines. There are, of course, always possibilities of error, from the fact that it is extremely difficult to make such spiral tubes of the same calibre throughout; and hence arise differences in the value of the scale divisions which are placed on the instrument. With tubes of a certain diameter, the effects of capillarity would also make a correction necessary. These defects could, however, be allowed for if frequent comparisons at all points of the scale were made with a standard barometer.

A very favourite method of increasing the range of a barometer consists in floating the tube in a cistern of mercury. The tube is filled in the usual way and inverted, and is kept floating upright by means of friction guides. In this arrangement the tube floats higher or lower, according to the amount of mercury which flows to and from the cistern. With some self-recording instruments of this type the tube is attached to one arm of a balance, and is counterpoised by a weight on the other arm. The recording pencil is sometimes attached to this weight, or the arm itself may be made to record the oscillations by means of a pointer attached to it. It is well known that substances of a less specific gravity than mercury have been used as the barometric fluid, and barometers in which the tube is filled with linseed-oil, glycerine, or water are quite familiar, the great water barometer, for instance, being a popular exhibit at the Crystal Palace about 30 years ago. These are the giants among barometers, and although they are of certain interest as individual instruments, there is not much hope of their race increasing, and in the search for a sensitive barometer, something that requires less house room will find favour with the ordinary person; but, whatever their size, there are few instruments in the armoury of the meteorologist so full of potentialities as these sensitive barometers.

Ages of Birds.—It is only possible at present to collect data from the duration of lives of birds in captivity; evidence otherwise must be very unreliable, and it is purely a matter of theory as to whether the natural possible life is greater than that under the unnatural conditions of captivity. There are records of a nightingale having lived 15 years, a thrush 17, a blackbird that was still alive at 20½, a goldfinch 23, and skylarks of 24 and 20. Ravens, owls, and cockatoos are popularly supposed to live to a very great age, and the following records appear to be authentic: raven 50, grey parrot 50 and 40, blue macaw 64, eagle owls 53, and one still alive at 68. Some aquatic birds live to a ripe old age, for we hear of a hereon of 60, goose 80, mute swan 70. It is doubtful whether any of the foregoing ages are any true guide as to the longevity of the actual families the birds represent, or, indeed, whether the possible age of one family exceeds that of another; but the records are interesting, and form a step in the ladder of the investigation of this most difficult question. Mr. Gurney makes the statement that the colouring of a bird in perfect health and texture of its feathers are exactly the same at 50 as at 5, and that those signs that are popularly put down to age, such as bleached and faded plumage and misshapen claws or beak, are attributable to unnatural conditions of some kind. The great tenacity of life some birds possess when deprived of food is marvellous, and the following instances are given: Golden eagle 21 days, an eider duck 28, and albatross 35, and a penguin (Aptenodytes), it is stated, can live two months.—*Ibis.*



TOOL-GRINDING MACHINE.

THE illustration shows a tool-grinding appliance invented and patented in December, 1898, by Mr. H. S. Ilsley, technical instructor at the Westminster Bridge Road Board School, and will be appreciated by all who have to grind their own tools. By its means, not only the experienced workman, but the amateur, is enabled to grind accurately and quickly any tool to its required angle, and it obviates entirely the necessity and expense of turning up the stone. It has, we understand, been adopted by the School Board for London for use in their manual training centres, by the Royal Military Academy, Woolwich, and many other school boards, technical schools, and colleges. It can be fitted to any grindstone, and requires no previous experience. A full description will be found in Messrs. Francis and Company's advertisement on another page, and from them further particulars may be obtained.

MILLWRIGHT'S WORK.—X.

COMMON loose pulleys are generally retained in position with loose collars. These are either solid or split. The first are mostly made

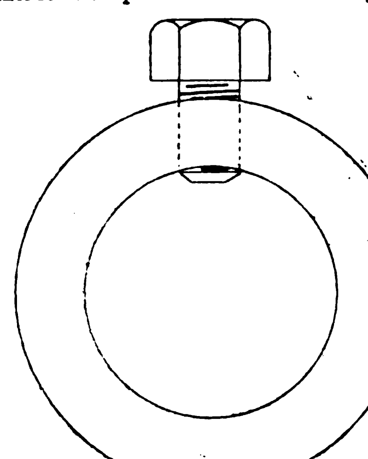


Fig. 58.

of wrought iron or steel, turned all over. Divided collars are chiefly in cast iron. The commonest type of solid collar, shown in Fig. 58, is a

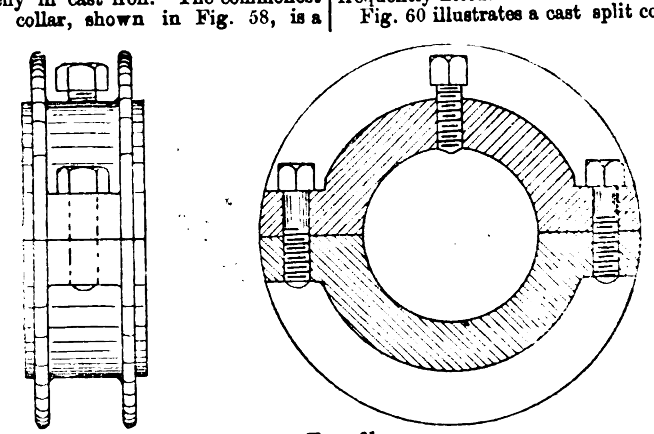

Fig. 61.

survival of an undesirable form, the only merit of which is its extreme simplicity. It is a little cheaper than the better ones, and these two features have insured its permanence. But it has been responsible, like the common coupling, for many accidents, and is not satisfactory in other respects. It lies open to the same objection as the ordinary coupling,—that it will only fit properly on a shaft which is of the same diameter as its bore. A thousandth of an inch, more or less, will cause a tight or a slack fitting. More-

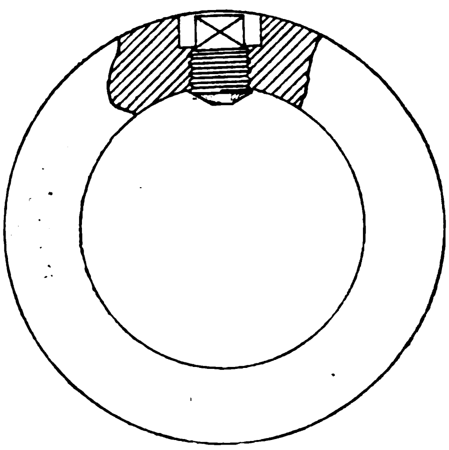

Fig. 59.

over, collars are liable to rust on their shafts, and the set-screws also rust up, and render their removal troublesome. Finally, they have to be slid on from the end, a generally undesirable arrangement.

The only improvement on the common collar is that in which the head of the set-screw is sunk

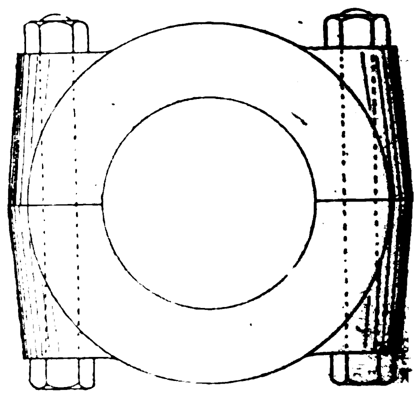

Fig. 60.

into a recess, Fig. 59. This avoids danger from entanglement with clothing, but leaves the remaining objections unaffected.

The set-screw in the figure has a square head, to take a box spanner. Sometimes the head is slotted, but the modern practice favours a screw, the head of which fills up the hole, and which has a square recess to receive a square tommy for tightening it up. In large collars two screws are frequently fitted.

Fig. 60 illustrates a cast split collar, with lugs to receive the bolts. It is not a desirable form, on account of the awkward way in which the bolt heads stick out. Fig. 61 is preferable, because the flanges protect the bolt heads. The

set-screw in this case is not always necessary, the gripping of the two halves being generally sufficient.

One of the best collars is that of Trier Bros., Fig. 62. It is not open to any of the objections just enumerated. The two halves are united

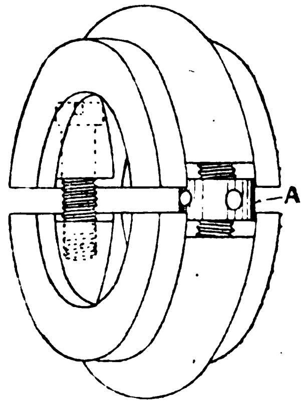

FIG. 62.

with screws. One screw is of the cheese-headed type, the other, A, is right and left handed, with a central boss and tommy holes. The collar being put on, the halves are nearly tightened with the double screw, then the cheese-head screw is run in tightly; the last grip is finally given with the double screw. The tightening of

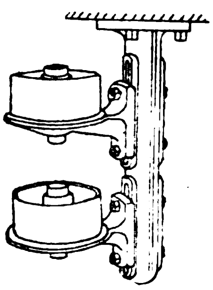

FIG. 63.

the latter screw keeps the former in tension, and prevents its becoming loosened by vibration. When closed thus, there are no projections, as the boss of the double screw presents the same section outside as that of the collar. The collar can be removed more easily than one which is driven or slid endwise over the shaft. A neat application of the Trier collar to a loose pulley was shown in the last article, Fig. 54.

Besides main pulleys there are numbers of

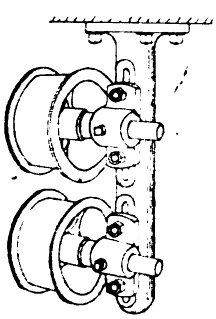

FIG. 64.

small ones which serve as guides, or binders or tighteners to the main driving belts. These are of small diameter, mostly under 12in. In some cases they are plain, in others they are double flanged, in others flanged on one edge only, as when they run in a horizontal plane. They often have to serve the functions of guides and binders. When they conduct belts at awkward angles it is frequently desirable to give them some range of adjustment for angle, hence the reason for the great variation in type which occurs.

Figs. 63—66 illustrate some guide pulleys as made by Croft and Perkins. In Fig. 63 a slotted bracket is bolted to the beam overhead. A bearing bracket slides in each slot in which it can be tightened within the range afforded by the slot, the belt running in a horizontal plane, and laying upon the flanges. Fig. 64 is a type for a belt running in a vertical plane, the bearing brackets

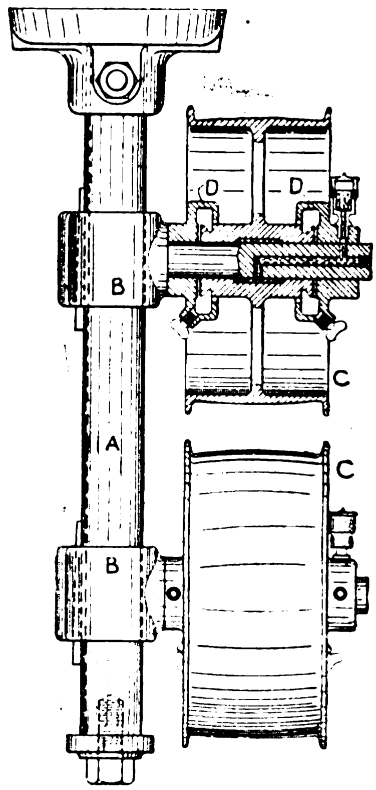

FIG. 65.

sliding in slots, and the pulleys running on pins pinched in the brackets with set screws. Pulleys without flanges can be similarly arranged. In another form the pulleys do not overhang, but run between bearings which are movable up and down a slotted plate.

In a third type, Fig. 65, the pulleys run on pins which have bosses adjustable vertically on a

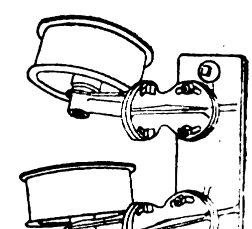

FIG. 66.

shaft of circular section. In this example special attention has been paid to the means of lubrication in conjunction with cleanliness.

The post A, of either cast or wrought iron, machined, and having a keyway cut its entire length, carries two trunnions, B B, of cast iron, bored to fit the post A, and having turned shanks

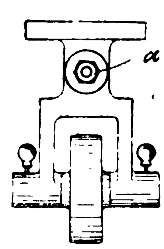

FIG. 67.

on which rotate the pulleys, C C, the shanks having a lubricating hole drilled up the centre, which is fed from a lubricator attached to the collar at the end of each shank. The trunnions B B are held in any position on the post A by means of keys. The two collars, D D, are arranged to form reservoirs for the waste oil, and catch it as it is thrown from the ends of the bosses of the guide pulleys. By removing a thumb-screw in each collar the waste oil may be run off.

In another type, Fig. 66, a universal movement is imparted to the pulleys by means of a double swivelling arrangement—one, that of the brackets, on the wall-plate, the other, that of the pulley-bearings, on the brackets in a plane at right angles with the first movement.

Fig. 67 is a binder-pulley which will swivel to any angle on the pin *a*.

ARTIFICIAL TEXTILE FIBRES.

THE following abstract of Mr. W. M. Gardner's opening lecture of the winter session in connection with the chemistry and dyeing department at the Bradford Technical College is taken from the *Textile Mercury*:—After describing the peculiarities of the three natural fibres, wool, cotton, and silk, Mr. Gardner said that if the structures of the three were contrasted, it would be seen that wool and cotton possessed a highly-organised or cellular structure, whereas silk, being merely a solidified liquid, had no special interior formation, thus resembling a thread of glass. It was therefore obvious that as regarded structure the silk fibre offered a much more promising field to the chemist who attempted its artificial reproduction than did the highly-organised wool or cotton. Given the requisite liquid, it would not be an insoluble problem to produce from it a

Fibre Resembling Silk

in every respect. On the other hand, it was hopeless to expect that an artificial fibre possessing the same internal structure as wool or cotton would ever be produced. No chemist had hitherto succeeded in reproducing the simplest body which exhibited a cellular structure. As regarded the chemical structure of the fibres, they found that cotton was the simplest in composition. Most of the artificial fibres were produced from cellulose as a basis, and thus were chemically more closely connected with cotton than with wool or silk; but one or two were obtained from gelatine, and thus approximated to silk. In appearance, however, they all, without exception, resembled silk rather than wool or cotton. The first attempts to produce a valuable fibre artificially consisted in dissolving waste solvent, and then saturating cotton yarn or thread in this solution, thereby greatly increasing the lustre. Mr. Gardner proceeded to mention a number of commercially valuable products formed by various reagents on cellulose, and similar to some of the artificial fibres in composition. Collodion silks constituted the ordinary "artificial silks" of commerce at the present time. The name, "lustro-cellulose," had been proposed for these products, but had not been generally adopted. It was proposed in 1894 to manufacture this product in England, and Bradford would in all probability have been fixed upon but for the fact that the heavy tax on alcohol in England rendered any manufacture in which it was largely used expensive. The works were, therefore, established near Zurich, but the company had an office in Bradford. The manufacture of art silk by the processes he had described might be considered as consisting in the solution of the cellulose, followed by its regeneration in the form of a fine thread, the increased lustre of the new fibre being due to its smooth external surface. Dealing with the action of reagents on cellulose, the lecturer said that the action of alkalis was not less interesting than the action of acids, since by the aid of alkalis several most important fibres, mercerised cotton, and several forms of viscose silk were obtained, as well as many other useful substances. The applications of the ordinary mercerising process were (1) to increase the affinity for dyes, (2) to produce crepon on cotton, (3) to produce crepons on wool, cotton, or silk-cotton unions. Now, it was possible to contract either the wool or the cotton in a mixed fabric. The most important outcome of the mercerising process, however, was the observation that by mechanically preventing the shrinkage which naturally occurred during the process, a greatly increased lustre was imparted to the cotton. By this simple modification of a fifty-year-old process, the textile industries had been enriched with what was practically a new fibre, which approached silk in lustre, but which was infinitely cheaper. He did not propose to embark upon the stormy seas associated with a discussion of the patent rights in connection with this process. Only during the last five years had it reached importance; but its enormous development, due largely to the skill and enterprise of the Bradford dyers, had been such that several thousand pieces of cotton cloth were lustred per day in that district, in addition to enormous quantities of hank and warp yarn. The magnitude of the trade was emphasised by the fact that, possibly for the first time on record, the value of the cotton material exported to the United

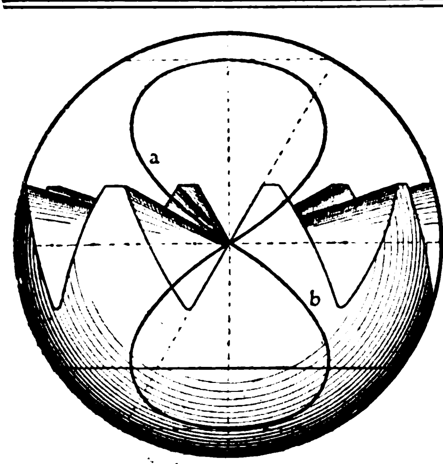

Fig. 1

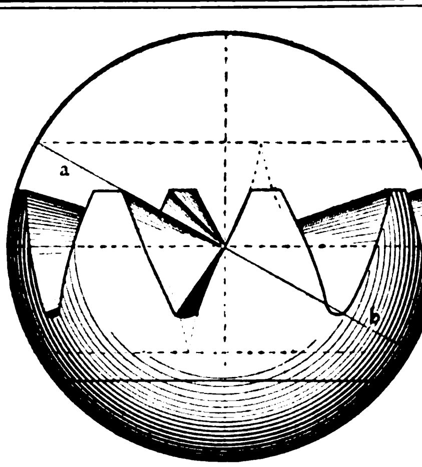

Fig. 2

States from the consular district of Bradford had, for the four months ended August 31, exceeded that of the dress stuffs, and was four or five times as great as the value normally exported during the same period. This was mainly due to goods lustred by mercerisation.

THE OCTOID SYSTEM OF GEAR TEETH.

SEVERAL readers have referred to the occasional use in our columns of the word "octoid," as descriptive of a system of bevel gear-teeth, and have asked for an explanation of the term. As this system is but little understood, and is often confounded with the involute system, a few words of explanation would seem to be appropriate.

The historical method of treating gear-teeth is to first determine the system of curves forming the outlines of the teeth, and the epicycloidal and involute systems are usually discussed from this standpoint. The rack being a special case of a gear, its profile is a special case of the general system of tooth curves, and by the above system of treatment the rack-tooth curve is the outcome of the general system of curves decided upon at the start, and, as is well known, in the involute system is a straight line. As is also well known, the profile of a gear-tooth may be assumed at random, and a mating or conjugate tooth may be found which will work correctly with the assumed curve, and with all similar conjugates belonging to gears of various sizes. In this way an indefinite number of tooth-curve systems may be originated. For instance, a gear might be made with circular tooth profiles, and mating curves might be found which would not themselves be circles, but which would mesh correctly with the original circular profile, and with each other. This original gear might be of any size, and it might be a rack.

Should such a rack be employed with straight profiles, the resulting conjugate profiles would be involutes, because the involute profile for a rack is a straight line. Again, had the rack a cycloidal outline, the resulting conjugates would conform to the epicycloidal system. This system of originating tooth-curves will be seen to be the reverse of the historical one. In the latter the rack-curve is at the end of the process, and is a development of the general system, while in the former it is at the beginning, and is the base of the system. The Fellows gear-shaper is an example of the newer method applied to spur gear-cutting, a straight-sided rack-tooth forming the starting-point of the system, from which a cutter with conjugate teeth is generated, and which in turn generates conjugate teeth in the gears. With the Fellows machine the resulting curves do not differ from those obtained in the usual way on the involute system, the difference between the Fellows and the older methods being mechanical rather than geometrical.

With bevel gears the analogue of the rack is the crown gear, the tooth profile of which is a special case of the general tooth-curve system, precisely as with a rack, and by assuming the crown tooth profile, various systems of bevel curves may be originated, as with a rack and spur profiles.

Now, while the rack-tooth profile of the involute system is a straight line, the crown-tooth profile of the same system is not, but is curved, as with other bevel teeth, and the adoption of a straight-sided crown-tooth results, therefore, in a new system of tooth-curves, which is called the octoid system. The straight-sided crown-tooth is adopted because, being the starting-point in these systems of construction, it must be easy to originate, and this condition is, of course, best met by the straight-sided tooth.

The name of the octoid system is derived from the fact that the form of the path of the point of contact with complete teeth is a figure-of-8 curve, as shown by the line *a b* in the accompanying Fig. 1, which represents an octoid crown gear. The octoid system was first employed, and in fact invented, by Mr. Hugo Bilgram, all bevel gears cut on his well-known generating machine having such teeth, and the same is true of all generated bevel gears which are originated from a straight-sided crown gear-tooth.

The octoid has been widely confused with the involute tooth, owing to the erroneous assumption that an involute crown gear-tooth has straight sides like a rack-tooth. The first publication of the facts was, we believe, contained in an article by Mr. George B. Grant, published in our columns for October 13, 1890, and since republished in his well-known book, "Odontics."

The difference between the octoid and involute crown gear-tooth can be seen by comparing Figs. 1 and 2, which are reproduced from those published in connection with Mr. Grant's articles. Fig. 1 shows the octoid, and Fig. 2 the spherical involute. With the latter the path of the point of contact is the great circle *a b*.—*American Machinist.*

TRAVELS IN ABYSSINIA.

IN the Section of Geography at the meeting of the British Association, Capt. Wellby gave an account of his recent travels in Abyssinia, in the course of which he said that King Menelek's capital consisted merely of an accumulation of huts, with the Palace or Ghébi of the King planted conspicuously on a small hill. The land in the valley was well watered and good, the climate invigorating, and the grazing all that could be desired. But there was no wood. Wood was brought in daily from a distance of 15 miles, and was comparatively the most expensive article in the market. At the time of his arrival in the capital with Capt. Harrington, King Menelek was about to march north with an army of 70,000 men, and he travelled with the King. While on the march he was struck with the thorough knowledge these so-called "savages" displayed of their own individual duties. One Sunday morning, when all were resting, the King with a lavish hand breakfasted his loyal subjects, governors of provinces, generals, and common soldiers alike. The meal mainly consisted of huge legs of raw, quivering beef, the repast being concluded in a most unexpected manner by glasses being handed round and filled with champagne. It was civilisation washing away barbarism. Though his sojourn in this Christian land was short, he could not help feeling convinced that when the Abyssinians had still further tasted the pleasures and profits of the civilised world, they would adopt more of its ways and customs, and it must be remembered that the Abyssinians had in a way lived independently, untouched by European nations and their inventive power, and thus they were, from our point of view, steeped in the most astonishing ignorance; but for all that there lay in them a mint of pluck, energy, and intelligence which was merely waiting for development. The Abyssinian dominion at the present day extended to a far greater extent south than was generally supposed. Some of the tribes who willingly bore the collar of subjection were apparently contented and well fed, while others, whose spirits were too elevated for subjection, had an opposite existence. Those who relied for food solely on milk and meat were of finer physique than those favoured with cereals as well, while those dependent on fish and vegetables were, as a rule, miserable looking. Furthermore, they dispelled the idea that fish was productive of a plethora of brains. Capt. Wellby said that a couple of days south of the capital they came to the sacred hill of Zagnala, on the summit of which he discovered a lake said to be of unfathomable depth. Looking from the summit of this hill he viewed the distant lake of Zouei, the first of a chain of three lakes connected by running streams. The water of the first he described as good and fresh, of the second as brackish but drinkable, and of the third as highly offensive to the palate. On the banks of the first two lakes were tribes living in a very poor way, but on the third was an independent tribe, which had never, so far as he knew, been visited by any white man. They evidently took him and his Somali companions for an Abyssinian party, and had not darkness come to his assistance he must have fared badly. Other tribes in the district displayed both friendship and hospitality. After crossing a belt of beautiful, though waterless, land, he entered the country of the Walamo, a people credited with the power of transferring the feelings and behaviour of a devil into the body of the stranger. Two theories had been suggested to him of the strange feelings experienced in this country—first, that the body was affected by the water of the district, which was probably impregnated by metals; secondly, as to the mental effects, it had been suggested that, without being aware of it, he was eating his meal before these people under a great mental strain; but the argument was rather beyond him. Further south lay the most picturesque district he had visited. He found hills nearly 11,000ft. high, some clad with slopes of green turf, and others with thick wood. From one of these high-lying camps another chain of beautiful lakes was seen, on the shores of which there existed a mark to commemorate the spot where Sacchi, the friend and doctor of Botego, was killed. Dropping into the plains, he steered for Lake Rudolph, or, more properly, Lake Gallop, where his escort of Abyssinian soldiers left his expedition to their own devices, their place being taken by 30 head of cattle, presents from the Abyssinians. Shortly before this he had come across a tribe called the Asilli. They always asked him for rain, as they entertained the notion that whenever thunder took place a white man was born, and thus the white man must always be able to bring rain. Probably they believed this because they had never seen a white woman. The western shore of Lake Gallop was a pleasant and inviting land, with an abundance of game, both fish, fowl, and meat. The climate was good and the scenery various. At this time the baggage animals were dying at an alarming rate from anthrax, and instead of eating their cattle they turned them into beasts of burden. Some travellers, he was told, adopted the plan of cutting steaks from the living animal, but they had no need to test this economical plan. From the southern end of the lake they struck a westerly course into the unknown before steering north again for the outlying Sudan post of Nasser, on the river Sobat, some 180 miles from its junction with the White Nile. During the journey of over 700 miles they discovered two sources of the Sobat, and came into contact with many more tribes, with all of whom they established a friendly feeling, the most interesting tribe met with being a race of giants. These savages stood in many instances 7ft. high. They wore rings of iron round their arms and necks, sometimes of such a ridiculous height that the head could only be moved slightly to the right or left. The hair hung over the shoulders to the waist, being further lengthened by the addition of a long stick resembling a tail. The end of the hair was turned up and formed a receptacle for knick-knacks. They carried two spears and a sleeping-pillow, and, like most savages, had no desire to stand before the camera.

GENIUS AND HEREDITY.

DOES the first-born have the best of it from the start? According to Prof. Axenfeld (in the *Rivista Moderna di Cultura*), all the men of genius are first-born sons. He says that eminent persons can be also the second or third children of a family, but a fourth, fifth, and sixth child will never be a great light. After a sixth child, the rest may again become men of talent. This is a terrible discovery. The poor fourth, fifth, or sixth sons, as they have no chance of having brains, are not worth giving a high education, and will make very mediocre husbands! Prof. Axenfeld quotes names to prove his theory, all mixed up any way: Luther, Schopenhauer, Francesco d'Assisi, Catherine of Medici, Guizot, Dante, Rafael, Leonardi da Vinci, Perugino, Luigi Gonzaga, St. Benedict, Charlemagne, Alexander the Great, Boccaccio, Confucius, Heine, Goethe, La Bruyère, Ariosto, Campanella, Mohammed, d'Alembert, Shelley, Christine of Sweden, Goldoni, Cantu, Buckle, Buffon, Talleyrand, Milton, Byron, Leopardi, Molière, Carlyle, Rossini were all first-born or only sons. Beethoven, Michael Angelo, Rousseau, Cuvier, Pascal, and Garibaldi were second sons. But there have been other famous men in the world. Cannot somebody produce some comfort for the late-comers in a family?

THE silk industry of China employs, it is estimated, from 4,000,000 to 5,000,000 people.

THE BRITISH ASSOCIATION.

ABSTRACTS OF REPORTS, PAPERS, &c.

Value of Gravity.

A GRAVITY balance invented by Prof. Pollock and Prof. Threlfall, F.R.S., was described by the latter. The apparatus consists essentially of a quartz fibre fixed at its ends and stretched horizontally. The fibre carries at its centre a light wire at right angles to its length, and loaded. The fibre is twisted until the wire is only just in stable equilibrium, under which circumstances a very small change in the value of gravity will cause it to tilt through a measurable angle. The author described the excellent devices by which the instrument has been brought to such perfection as to enable him to detect changes in gravity which amount to less than two-millionths of the whole acceleration of gravity. The instrument is portable, and has been used in a coast survey of Australia, during which it travelled 6,000 miles; since then it has been brought to England, and its sensitiveness is unimpaired. The short pendulums used in the United States Coast Survey gave results accurate to four parts in a million, this being, however, the mean of observations with three such pendulums, and not the record of a single instrument. Prof. Vernon Boys, F.R S., congratulated the author on the new use to which he had put quartz fibres.

The President, Prof. Poynting, said that when the Committee on Gravity Meters was appointed in 1884, they asked for designs for an apparatus to measure changes in gravity amounting to one part in 100,000, and they would have been satisfied with less than this. He was glad to notice the improvement which had taken place since that time. Prof. G. H. Darwin, F.R.S., stated that he would draw attention to Prof. Threlfall's apparatus at the International Geodetic Conference.

Seismology.

The report of the Seismological Committee was presented by Mr. G. J. Symons, F.R.S. It contains details of many observations on earthquakes during the past year from the different stations at which seismographs have been established. A section is devoted to a discussion of the earthquake registers, and is followed by one on varieties of earthquakes and their respective durations. On this subject Prof. Milne remarks: "The shiverings of our world recur on the average every 30 minutes, but the heavy breathing or true ground-swell does not happen more than once a week. Popularly they are both earthquakes, but they differ in their character, in their duration, and probably in their origin, and as they radiate their life, as exhibited at stations further and further remote from their origin, rather than increasing, becomes less." The question of so-called earthquake-echoes is next discussed in detail. An earthquake disturbance as recorded at a station far removed from its origin shows that the main movement has two attendants, one which precedes and the other which follows. The first of these by its characteristics indicates what is to follow, whilst the latter in a very much more pronounced manner will often repeat at definite intervals, but with decreasing intensity, the prominent features of what has passed. Inasmuch as these latter rhythmical but decreasing impulses of the dying earthquake are more likely to result from reflection than from interference they have been provisionally called echoes.

Kite Meteorology.

An account of work done at the Blue Hill Observatory, Massachusetts, by the aid of kites, was given by Mr. A. L. Rotch. The average of the highest points attained by the meteorograph in each of the 35 flights during 1898 was 7,350ft. above the sea, the average of the ten flights during the first four months of 1899 was 7,680ft., and that of the five flights between Feb. 23 and 28 was 10,280ft. The maximum height attained in 1898 was exceeded by 370ft. on Feb. 28 this year, when an altitude of 12,440ft. was reached. The increase of altitude was smaller than in previous years, and this indicated that the extreme height to which the kites could rise was being approached. The features of the Blue-hill practice that enabled great heights to be reached were the use of cellular kites having curved surfaces, giving greater lift, with self-regulating bridles limiting the wind-pressure on each kite, and the attachment of the kites at different points on the wire, whereby their pull was distributed. Some important meteorological results had been obtained during the past year. The value of kites for meteorological observations, as demonstrated at Blue-hill, had led to their trial in the United States and in Europe. The attempt of the United States Weather Bureau to secure each day records with kites a mile above 16 stations was unsuccessful for forecasting on account of light winds, which prevented daily flights at all the stations; but many data were obtained simultaneously in the free air and at the ground. The German and Russian Meteorological Bureaux would employ kites at Hamburg, Berlin, and St. Petersburg; and at Trappes, near Paris, M. L. Teisserenc de Bort has already got records at great heights. It appeared, therefore, that henceforth the equipment of a meteorological observatory should include the kite (and perhaps the captive balloon, for use when wind was lacking), so that automatic records might be obtained at the height of a mile or two in the free air at the same time as observations on the ground.

Standard Thermometry.

The best means of measuring and recording temperature formed the subject of a note by Prof. H. L. Callendar, F.R.S., and in the course of his remarks he said:—The gas thermometer, which had so long been adopted as the theoretical standard, had given results so discordant in the hands of different observers at high temperatures as greatly to retard the progress of research. The arguments in favour of the platinum resistance thermometer as a practical standard given by the speaker in 1886 had since been confirmed and strengthened by the work of many independent observers. The proposals were:—(1) That a particular sample of platinum wire be selected, and platinum resistance thermometers constructed to serve as standards of the platinum scale of temperature. (2) That the scale of temperature deduced from the standard platinum scale by means of a parabolic formula which has been proved to give a very close approximation to the true or thermo-dynamic scale, be recommended for adoption as a practical standard of reference, and be called the British Association scale of temperature. It should be noted that the gas thermometer would still remain the ultimate or theoretical standard, and the exact relation of the British Association scale of temperature. It should be noted that the gas thermometer would still remain the ultimate or theoretical standard, and the exact relation of the British Association scale to the absolute scale would be the subject of future investigation. In the present state of experimental science the difference between the two scales over the greater part of the range was less than the probable errors of measurement with the gas thermometer, and the possible accuracy of measurement with a platinum thermometer, especially at high temperatures, was of a much higher order than with the gas thermometer.

Rearing Sea-Fish.

An account of the experiments at Plymouth made by Mr. Walter Garstang on the artificial rearing of sea-fish was read by that gentleman, who, in the course of his remarks, said that the only successful experiments hitherto had been conducted by Dr. Meyer, of Kiel, who had reared the fry of the Baltic herring, and by Mr. Dannevig, who had reared the fry of the plaice. This summer he himself undertook some experiments with the larvæ of the butterfly-blenny (Blennius ocellaris). The first problem was to determine what volume of water was necessary to healthy development. At first he placed 25 just-hatched larvæ into a two-gallon jar. In the first experiment, however, the water was not fresh, and all the larvæ were dead in five days. Two other similar jars, containing fresh sea-water and the same number of larvæ each, were then placed, one in a window so that the light had full access, and the other in a tank of water maintained at a constant temperature. In the former case, the larvæ were all dead at the end of ten days, and in the latter case the death-rate was smaller, though only one of the larvæ survived to the fifteenth day. It appeared to him that in these experiments the jars had been too crowded, and so, in the next experiment, only 19 larvæ were placed in the jar, which was immersed in water kept at a constant temperature. For more than a week all the larvæ survived; and at the end of twenty days the larvæ were so healthy that they were taken out of the jars and placed in an aquarium with circulating water. There were six or eight of them alive a week ago, and only one had died since he left. A large part of the actual mortality was due moreover to preventible accidents which had no bearing on the conditions of the experiment; but these experiments convinced him that in stagnant water not more than ten larvæ could be reared in two gallons of sea water; and when he put this opinion to the test he found that there was a very slight mortality, and at the present moment he had larvæ five weeks old and in a healthy condition. The success of these later experiments he attributed largely to the fact that he employed "plunger" jars, in which the water at the bottom of the jar was being constantly drawn up to the top. This mechanical stirring of the water in the jars was very necessary in the early period of the cultivation of the fry. There was a very high mortality among the larvæ when placed even in large tanks if the water was not stirred. His investigations showed that it was possible to determine in the laboratory the conditions in which the larvæ of sea-fish might be safely brought through the critical stage of their development. During the coming season he intended to renew his experiments with the larvæ of several food fish.

Report on Water Analysis and Sewage.

An interim report was presented by the committee, consisting of Profs. W. Ramsay (chairman), Dr. Rideal (secretary), Sir W. Crookes, Prof. F. Clowes, Prof. P. F. Frankland, and Prof. R. Boyce, in which it was stated that it is desirable that results of analysis should be expressed in parts per 100,000, except in the case of dissolved gases, when these should be stated as cubic centimètres of gas at 0° C. and 760mm. in one litre of water. This method of recording results is in accordance with that suggested by the committee appointed in 1887 to confer with the committee of the American Association for the Advancement of Science, with a view to forming a uniform system of recording the results of water analysis. [Brit. Assoc. Report, 1889.] The committee suggest that in the case of all nitrogen compounds the results should be expressed as parts of nitrogen over 100,000, including the ammonia expelled on boiling with alkaline permanganate, which should be termed albuminoid nitrogen. The nitrogen will, therefore, be returned as: (1) ammoniacal nitrogen from free and saline ammonia; (2) nitrous nitrogen from nitrites; (3) nitrous nitrogen from nitrates; (4) organic nitrogen, either by Kjeldahl or by combustion, but the process used should be stated; (5) albuminoid nitrogen. The total nitrogen of all kinds will be the sum of the first four determinations. The committee are of opinion that the percentage of nitrogen oxidised—that is, the ratio of 2 and 3 to 1 and 4—gives sometimes a useful measure of the stage of purification of a particular sample. The purification effected by a process will be measured by the amount of oxidised nitrogen as compared with the total amount of nitrogen existing in the crude sewage. In raw sewage and in effluents containing suspended matter it is also desirable to determine how much of the organic nitrogen is present in the suspended matter. In sampling the committee suggest that the bottles should be filled nearly completely with the liquid, only a small air bubble being allowed to remain in the neck of the bottle. The time at which a sample is drawn, as well as the time at which its analysis is begun, should be noted. An effluent should be drawn to correspond as nearly as possible with the original sewage, and both it and the sewage should be taken in quantities proportional to the rate of flow when that varies (e.g., in the emptying of a filter-bed). In order to avoid the multiplication of analyses the attendant at a sewage works (or any other person who draws the samples) might be provided with sets of 12 or 24 stoppered ½ Winchester bottles, one of which should be filled every hour or every two hours, and on the label of each bottle the rate of flow at the time should be written. When the bottles reach the laboratory quantities would be taken from each proportional to these rates of flow and mixed together, by which means a fair average sample for the 24 hours would be obtained. The committee at present are unable to suggest a method of reporting bacterial results, including incubator tests, which is likely to be acceptable to all workers.

Action of Light upon Metallic Silver.

A paper by Col. J. Waterhouse on the "Action of Light upon Metallic Silver" was read by Mr. J. Spiller. It stated that when cut masks are laid on the surface of silver leaf or foil, or on a Daguerreotype plate, and exposed to the sun's rays, a visible image ultimately appears on the metallic surface. The effect is produced more rapidly if the metallic surface has been exposed to mercury vapour or immersed in an acid solution of a ferrous salt mixed with nitrate of silver. Copper and probably other metals are sensitive in the same way.

Electrolytic Solution Pressure.

In a note on this subject Dr. R. A. Lehfeldt discussed the theory of electrolytic solution pressure, in which he stated that, according to Nernst's theory, when a metal is immersed in an electrolyte a minute amount of its goes into solution in the ionic form, giving a positive charge as the liquid as compared with the metal, or ions from the solutions are deposited in metallic form, giving the metal a positive charge according as the osmotic pressure of the ions in solution falls short of or exceeds an amount known as the electrolytic solution pressure. This view had been generally adopted by physical chemists, it being supposed that the amount of metal to be deposited or dissolved was too small to measure. By combining the calculated value of the solution pressures with the known theorems of electrostatics on the tension exerted by electric charges, it might be shown, in the case of zinc at least, that the amount dissolved would be some centigrammes per square centimètre immersed, and could be easily weighed. Hence the theory seemed to break down.

Grants in Aid.

The following grants of money in aid of scientific research have been made by the British Association through the general committee. The asterisk means "re-appointed," and the sums are pounds sterling. In some cases there is sufficient money in hand, and

grants were not made:—MATHEMATICS: *Lord Rayleigh, Electrical Standards (£300 in hand), £25; *Prof. J. W. Judd, Seismological Observations (£9 5s. 4d. in hand), £60; *Prof. G. F. FitzGerald, Radiation in a Magnetic Field, £25; *Prof. A. W. Rücker, Magnetic Force on board Ship, £10; *Prof. H. L. Callendar, Meteorological Observatory, Montreal, £20; *Lord Kelvin, Tables of Mathematical Functions, £75; CHEMISTRY: *Prof. W. N. LEVERAGE OF THE LOCOMOTIVE DRIVING-WHEEL—WHY THE LOCOMOTIVE MOVES.*

PLEASE explain why a locomotive moves. It may be simple enough to anyone who knows; but there are several of us mixed up on it. What I mean is, how is the power applied to the wheels during an entire revolution? Take a locomotive when the pin is on the bottom quarter, going ahead. What are the points of the lever in the wheel? Is the fulcrum at the centre of the axle, at the crank-pin, or at the point of contact with the rail? It is easy enough to understand a stationary engine. The front and back cylinder-heads form the resistance for the steam to push the piston; but when you consider a locomotive when the main pin is on the bottom quarter, going ahead, it seems to several of us that the piston forms the resistance, and the front cylinder-head pulls the locomotive along. That would change the point on the driving-wheel at which the power is applied.

In reply to the inquiry of our correspondent we would say that the problem is one that may be better presented by a graphical illustration and somewhat lengthy treatment. For simplicity we will confine our observations to one side only of the engine.

Fig. 1 shows the direction of the force applied by the main rod A on the pin B. As we are concerned only with horizontal forces in the movement of the locomotive along the track, we can resolve, by the law of parallelogram of forces, this oblique or angular force exerted by the main rod into perpendicular and horizontal forces p and h respectively. As p is of no value in this problem, we will omit it, and retain only the horizontal force h, which will henceforth be known as P, the actual horizontal pressure exerted on the pin by the main rod. Thus we will avoid all entanglements with, and need make no further reference to, the angularity of the main rod in dealing with this problem.

Fig. 2 shows the driving-wheel acted upon by P, the force at the pin P_1, the driving-box resistance, and P_2 the force at the point of contact between the wheel and rail. The arrows indicate the direction the forces are acting—viz., P and P_2 are forward, and P_1 is backward. Thus we have a lever of the second class, whose arms are respectively 12in. and 30in., and which is fulcrumed at P_2. The force exerted on the pin, we will say, is 10,000lb. Now we know the two lever-arms and the force P_1, and will proceed to find the two unknown forces P_1 and P_2. At the instant before the wheel starts to revolve there there is an equilibrium of forces about the fulcrum point P_2; i.e., force P, multiplied by its lever-arm (the distance between P and P_2, which is 42in.), is balanced by the opposing force P, multiplied by its lever-arm (the distance between P_1 and P_2, which is 30in.)

This we will state by the equation

$$P_1 \times 30 = P \times 42;$$

or, substituting the known value of P, which is 10,000lb., we have—

$$P_1 \times 30 = 10,000 \times 42;$$

or, multiplying together the terms in the right-hand side of the equation, we have—

$$P_1 \times 30 = 420,000.$$

Now, P_1 is an unknown quantity; but we can find its value, for we know, as the equation states, that 30 times P_1 is equal to 420,000. Therefore P_1

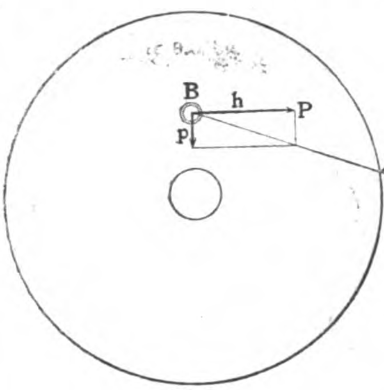

Fig. 1

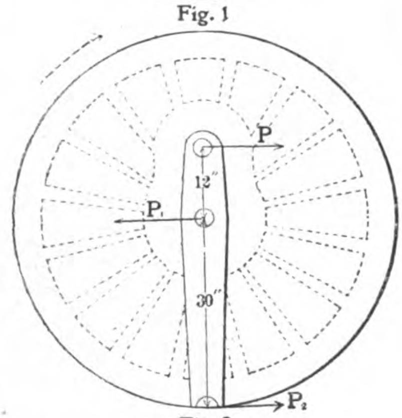

Fig. 2

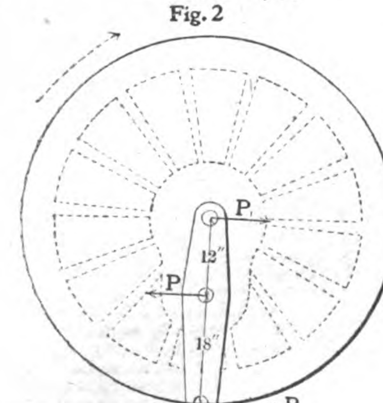

Fig. 3

itself must be equal to one-thirtieth of 420,000, which is 14,000. Now, as we know that the value of P_1 is 14,000, and of P is 10,000, we will put the figures instead of the letters in the equation—

$$P_1 \times 30 = P \times 42,$$

and we will have—

$$14,000 \times 30 = 10,000 \times 42;$$

or, performing the multiplication, we have—

$$420,000 = 420,000.$$

Thus equilibrium is proved.

Now that equilibrium of the forces has been proved, what have we accomplished that is useful? The answer to this question is that we have a proof that at the instant before the wheel begins to revolve, the forward-acting force of 10,000lb. on the pin at the upper end of the lever just balances the backward-acting force of 14,000lb. on the axle at the middle point of the lever. Now that this is proved, another step can be made. We will add enough more steam-pressure to the piston to increase the force on the pin to, say, 10,001, instead of the even 10,000 as before. Now equilibrium is broken (for 10,001 times the lever-arm, 42, equals 420,042, and is greater than 14,000 times 30in., which equals 420,000), and the lever will start to rotate about its fulcrum, P_2, and move in the direction of the greater force, which is to the right. Thus the wheel begins to roll to the right, and the engine moves forward.

Let us return for a moment to the lever held in equilibrium, as shown in Fig. 2, for we have not yet found the value of P_2, the adhesion between the wheel and the rail. To find the value of P_2, we will assume the fulcrum (during this part of the computation) to be at P, the pin. This assumption gives a forward force of P_2 multiplied by a lever-arm of 42in. balancing a backward force, P, multiplied by a lever-arm of 12in. Putting this in the form of an equation, we have—

$$P_2 + 42 = P_1 \times 12.$$

But P_1 has a value of 14,000lb., as proved. Putting this in, we have the equation—

$$P_2 \times 42 = 14,000 \times 12;$$

or,

$$P_2 \times 42 = 168,000.$$

We do not know the value of P_2; but we do know, as the equation states, that 42 times P_2 is equal to 168,000lb. Hence P_2 must be the one forty-second part of 168,000lb, which is 4,000lb. To prove this, and also to prove our right to assume the fulcrum to be at the pin during this part of the computation, the forces directed forward must balance those directed backward—i.e., $P + P_2$ must $= P_1$, or $10,000 + 4,000 = 14,000$. This is done, and is therefore proved.

We will now rotate the wheel ahead one half-revolution, as shown in Fig. 3, which places the pin on the lower quarter. This gives us a lever of the third class, where the force P is applied at the middle point of the lever, and the fulcrum is still at the point of contact between the wheel and the rail. Again, at the instant before the wheel starts to revolve, and the lever to rotate about the fulcrum P_2, the forces pointing to the left multiplied by their lever-arm must equal those pointing to the right multiplied by their lever-arm. Putting this in the form of an equation, we have—

$$P_2 \times 30 = P \times 18.$$

As the pressure at the pin is the same on the lower quarter as on the upper, we can replace the letter P in the equation with 10,000lb., thus—

$$P_1 \times 30 = 10,000 \times 18;$$

or,

$$P_1 \times 30 = 180,000.$$

If 39 times P_1 is equal to 180,000lb., as the equation states, then P_1 itself is equal to one-thirtieth of 180,000lb., which is 6,000lb. Therefore P_1 equals 6,000lb.

Now that we know both the forces P and P_1, we can easily determine P_2; for $P_1 + P_2$ together oppose and hold P in equilibrium. Hence P_2 is the difference between 10,000lb. and 6,000lb. (P and P_1), or 4,000lb. Thus it will be seen that the forces on the pin and the rail above the centres are the same as those on the pin and rail below the centres. One notable difference, however, is the pressure of the axle in the driving-box, which is greater while the pin travels through the half-revolution above the centres than that below. This is true whether the engine be running forward or backward.

Thus we learn that while the pin travels through the upper half-revolution, we have a lever of the second class, which gives the same pressure on the pin and pull on the rail as that had during the revolution through the under half, when the lever is of the third class. The progress of the engine through space should, therefore, be uniform.

Beginning at the back centre, as the engine moves ahead one half-revolution of the driving-wheels, the cylinders, frames, and other fixed parts of the locomotive move forward through space a distance equal to one-half the circumference of the driving-wheels, which is equal to one-half the diameter of the wheel multiplied by 3·1416 (30 × 3·1416), or 94¼in. During this half-revolution the piston pulls away from the back cylinder-head, and, with the second-class leverage in the wheel, pulls the locomotive along. The absolute travel of the piston through space is, therefore, 94¼in. + 24in. (the stroke), or 118¼in.

As the wheel completes the revolution, moving the pin from the forward centre through the lower half-revolution to the back centre, the fixed parts of the locomotive move through 94¼in. more space, making 188½in. in all. The piston, through this half-revolution, now loses 24in., and travels, therefore, but 70¼in. forward. Through this half of the revolution the piston forms the resistance, moving forward more slowly than the cylinder-head, which

* By F. M. NELLIS, in *Locomotive Engineering*, N.Y.

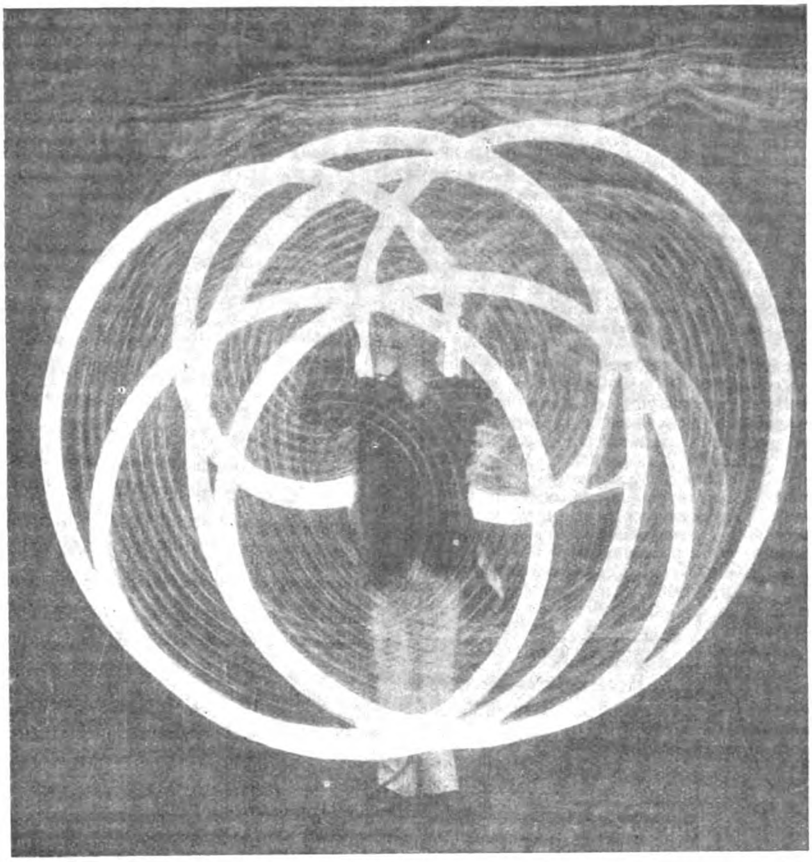
pulls ahead whilst the piston forms the resistance. The pressure on the piston through the lower half-revolution is exerted on the third-class leverage in the wheel.

The only times during the revolution that the piston stands absolutely at rest (in relation with the ground) is at the two dead-centres.

A MARINE ENGINEERS' LABORATORY.

THE Institute of Marine Engineers, that has its "home" in the Romford-road, Stratford, E., has been recently considering the best means of establishing a "laboratory" for the instruction of students, and also for the depositing of the experiences of those engineers who have made many trips over the seas. Mr. G. Halliday read a paper at the last meeting, in the course of which he said that, some years ago, it was the intention of Mr. Macfarlane Gray and Sir John Fortescue Flannery to establish a laboratory in connection with the institute, which would serve as a means of education to the younger members who might be at home or to members who might be at home from abroad. There was a difficulty, he believed, with regard to rooms. About the beginning of this year a small committee, with the best encouragement from the council of the institute, began to make some simple and inexpensive experiments in the rooms of the basement. They were simple experiments, and the making of them did not interfere with any of the other work going on at the same time in the institute. After the first experiments had been successfully carried through others were made, and before the committee almost had time to think where it had got to, it found itself in possession of thirteen sets of apparatus, each set furnishing the means to perform a separate set of experiments. Mr. Halliday read a list of the sets of experiments, and continued: Considerable progress has been made in the direction of furnishing the apparatus for a marine engineers' laboratory. It has only just been made known to the council that so many as thirteen sets of apparatus had been got together. As soon as it became known that so many sets of apparatus had been got together, the question arose what to do with them. How were the sets of apparatus to be arranged so as to be best available and of most use to the members? After the matter had been considered, the council agreed to place at the disposal of the experimental committee three rooms of the institute building. It was a wise idea of the founders of the institute that they should try to create a feeling in the members scattered over the seas that they should consider the building in the Romford-road a kind of shrine. When they returned after many days the feeling would draw them towards it as the Arab is drawn towards his Mecca. To enhance this view the founders made it a rule that each member should give something of his own to the institute, something to which his name would for all time be attached. It has thus come about that engineers, as wanderers in distant parts, when they saw wonderful things, thought of the old place in Romford-road, and brought them home to be seen by the members there. During this year those at home as well as those abroad have directed their energies in a common groove, and have begun to furnish the apparatus for a fully-equipped laboratory. The committee and the younger members, the associates, and the graduates, are devoting time and work to the business, and, with quiet persistence and energy on their part, will soon have something to be seen by members when they come to the place. And the committee would suggest that each member of the institute would of himself put the rule in operation which recommends that each member should present something to the institute during his membership. The work of the marine engineers' laboratory will not cross the work of the laboratories connected with the colleges. Their work is distinct and different. Engineers could not be prepared for the examination certificates of the Board of Trade at the ordinary technical college, because the staff of these colleges are trained in general engineering; they are not specialised for the examinations of the Board of Trade. The kind of experiments which will be made, and the laboratory work taught, will be on questions which are raised in the discussions in the institute, and in conversations with those who are engaged in marine engineering in their every-day life. The laboratory work will be distinct and different from that of other laboratories, and will be specialised accordingly. There is another advantage to the members from the possession of a laboratory. Much could be said of the influence on the mind of making experiments, which give exact knowledge and clear ideas. Much also could be said as to the moral influence which making experiments exerts on the man who makes them. After all, the very existence of this institution is primarily for the improvement of the members, and for raising their status—mental, moral, and social.

WILLOW and poplar corks are now used for champagne bottles by some wine producers.



EFFECTS WITH ELECTRIC LAMPS.

THE following example of the persistence of vision is described by the *Scientific American*:—Mr. George W. Patterson, of Chicago, has favoured us with a photograph of an "electrical spectacular effect," which he produces at entertainments which he gives. The graceful figures of light shown in our engraving are produced by electrically lighted Indian clubs swung in a darkened room. The club is of special construction, and the current is supplied by flexible wires inclosed in a rubber tube. Three series of 8, 3, and 1c.p. coloured lamps are set in sockets in the club at right angles to the centre of the club, which is split lengthwise. At the tip of the club is a 32c.p. lamp. When the clubs are swung at ordinary speeds the effect is very beautiful, an operator behind the scenes manipulating a switchboard turning on and off the lights in the two clubs, which are swung to music. The patterns are almost infinite in their variety, and suggest the engine-turning on our bank bills. Storage batteries furnish the current when the regular incandescent circuit cannot be tapped.

THE "A. B. C." JOURNAL BEARING.

THE purpose of this new bearing, which is manufactured by the Atlantic Brass Company, 192, Broadway, New York, is to provide means for transmitting the load to the journals uniformly throughout the length of the journal, in order to prolong the life of the brass and prevent heating. To accomplish this the load is transmitted from the box to the brass through a "wedge," which has an adjustable contact with the brass, the surfaces of contact being such as to permit the brass to load the journal uniformly, in spite of the tilting and transverse movements of the box.

In the M. C. B. box no provision for self-adjustment is made, and the lives of brasses are often very short, because of a concentration of the load at or near one point. This is sure to occur when the truck-frame tilts even slightly, and its effect is seen in examining M. C. B. brasses, which very seldom wear uniformly throughout their length.

The engravings show the self-adjusting surfaces, which are ingeniously arranged. The brass has a cavity in the centre of its upper face, into which a segment of a sphere on the under side of the wedge fits. The cavity in the brass is slightly elongated, for the purpose of giving an easy adjustment of the wedge and the brass. Other spherical surfaces outside of those at the centre help to carry the load, and, as shown in Fig. 1, they cause the wedge to rise on the top of the brass when subjected to side thrusts, and even under these thrusts the load is carried uniformly to the journal. A projection at the centre of the brass passes into an elongated hole in the wedge and prevents excessive side motion due to emergency thrusts. The spherical surfaces bear such a relation to each other as to cause the weight of the car to be raised by side thrusts, causing a tendency to restore the bearings to their normal condition again afterwards. Such thrusts are resisted and cushioned by the action of the wedge and the box.

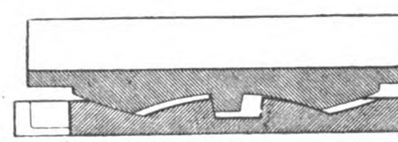


Fig. 1.

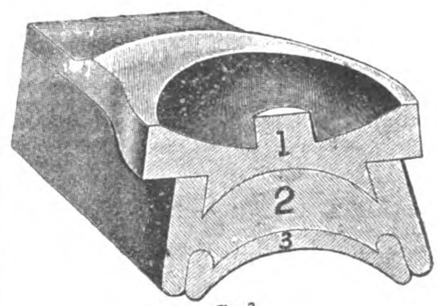

Fig. 3.

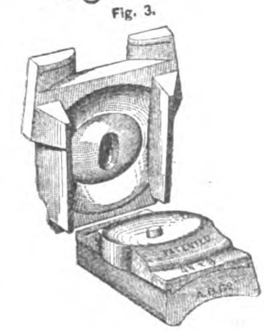

Fig. 2.

A section through the brass is shown in Fig. 3. It is also ingenious, and is made in three parts: 3 is the anti-friction bearing and metal lining; 2 is the bronze backing for the soft metal; and 1 is a cast steel back, which is strong and stiff, and is fused or welded to the bronze part. In earlier forms the

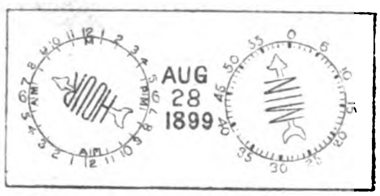
bronze part was riveted to the cast-steel back; but even moderate heating of a bearing made the rivets brittle, and the fusing was devised to overcome that difficulty. The union of the metals when seen in a section of a brass is close, and apparently very strong. The cast-steel back not only strengthens the structure, making it stiffer than if of solid brass, and therefore less likely to break transversely; but it also reduces the cost.

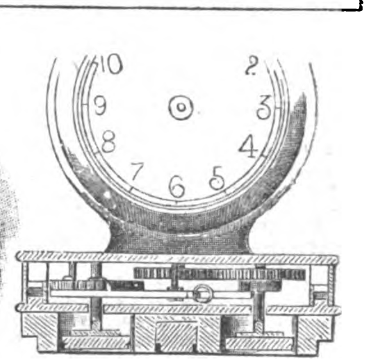
The brass and wedge when used together will fit the M. C. B. box, and the wedge of this adjustable bearing may be used with an M. C. B. brass in the M. C. B. box, so that this bearing will give no trouble on the road whenever a new brass may be required, if an M. C. B. brass is at hand. Experience with these bearings appears to support the claims made for them, and the first cost ought to be much less than that of the ordinary brass. The lubrication of journals ought to be improved by distributing the load uniformly, and it is fair to expect a reduction of train resistance from the smaller amount of friction. It is most important that no change in the boxes is required for these bearings, and also that there is no increase in the number of parts. It is seldom that such a simple device receives the careful study given to this bearing. Some of these bearings have been in constant use in passenger service since November of last year, and are reported to be in excellent condition. Other bearings made on this plan, but with riveted cast-steel backs, have been in constant service since July, 1897.—*American Engineer and Railroad Journal.*

A TIME-STAMP FOR BUSINESS USE.

In many lines of business it is a matter of great importance to record the exact time of acts, operations, or transactions, and to note upon papers and articles of various kinds the time of receipt or departure. A simple stamp by means of which such times can be recorded has been placed upon the market by Samuel H. Hoggson and Company, of 27, Thames-street, New York City, and possesses certain features of construction which are interesting from a mechanical point of view. The time-stamp comprises essentially a watch held in a body supported above a printing base. The printing base is provided with two recessed printing dials. Minute and hour shafts respectively extend within the recesses of the minute and hour dials, and have printing hands normally resting above the dials. By means of gearing the minute and hour shafts are so connected with the watch mechanism that the minute and hour hands of the shafts are made to rotate in unison with the corresponding hands of the watch.

The body of the stamp, in which the watch is carried, is yieldingly supported above the printing base and is movable with the time-printing hands. The parts are so assembled that when the base carrying the dials is pressed against a piece of paper, the printing hands in the dial recesses can be forced into contact with the paper by depressing the body of the stamp. The time thus stamped upon the paper will coincide with the time indicated by the watch. The hour dial, it will be observed, has two series of twelve graduations each. Owing to the arrangement of these graduations, it is unnecessary to provide any changing device to denote the "A.M.," "P.M." and "M." divisions of the twenty-four hours, for it is immediately apparent that the upper half of the dial denotes day and the lower half night. In operation the stamp is pressed upon an inked pad, then upon the article to be marked, a very slight pressure sufficing to insure a legible impression, giving year, month, day, and minute, together with any wording desired around the dials. The stamp is only 4½in. high, and weighs 10oz.—*Scientific American.*





SEPARATION OF THE LENSES IN STEREOSCOPIC WORK.

A correspondent asks us to devote an article to the subject of the adjustment of lenses in stereoscopic work. The reason he gives for his request may be thus stated. In ordering a stereoscopic camera to be made with the lenses so attached to the front that their distance of separation could be varied, he was met by the following pronouncement from the firm of camera-makers with whom he was in communication:—"We note what you say with regard to the adjustment of lenses for different distances, but we are still of opinion that it is more of a theory than of practical value, and this view of the case is also shared by Messrs. ——, to whom we have referred the matter."

We are aware that many firms who, in America and this country, as well as on the Continent, make hand and stand stereoscopic cameras for general use, do not trouble to give an adjustable movement to the lenses, for the obvious reason, of course, that amongst stereoscopic photographers there is very little call for the useful power which this convenience would place in their hands. Nevertheless, amongst the comparatively few persons who have a thorough grasp of the underlying principles of stereography, and the important bearing they have as regards correctness of application to practical ends, the utility of adjustable objectives in binocular work is so great that we may profitably take occasion to point out a few of the many reasons why that power is practically, as well as theoretically, of value.

In binocular vision our appreciation of relief, height, and distance is governed entirely by the power of axial convergence which our eyes possess. If we look at an object which is situated, let us say, at a distance of half a mile, the optic axes are virtually parallel; at any rate, the parallactic angle is so small that no sensation of relief results. In other words, as regards an object situated at the distance named, the two eyes, instead of seeing dissimilar views of it, as in the case of objects situated only a few feet or yards from the observer, virtually perceive them as identical. There is no "seeing round" either the one side or the other of the two similar views which are transmitted to the retina.

What applies to the eyes in the case of this narrowness of parallactic angle applies also to the lenses on the camera front. No relief is seen in distant parts of the binocular photograph; but the comparison does not hold good when we come to objects situated within a few feet or yards of the camera. The eyes, by their powers of accommodation and axial convergence, see those objects in natural relief; but, inasmuch as the lenses situated at a distance, we will suppose, of three inches from centre to centre on the camera front, possess neither the power of accommodation nor that of axial convergence, they impart to those objects, when they are viewed in the prints, an aspect of excessive or rather exaggerated relief. They see too much round the subject. Let the portrait of a person be taken with three-inch separated lenses, four or five feet from the camera, and the effect described will be at once apparent in the stereo-photograph.

It can be seen, therefore, that the need of adjustability in lenses for binocular work is a real, and not an imaginary, one. Suppose one is photographing a vase of flowers, situated a few feet from the camera. In practice, a separation of two inches is sufficient to give natural as opposed to strained relief, which would make the object have a cut-out or model-like appearance. In portraiture a separation of two and a half inches suffices. For interiors and landscape work, three inches should separate the centres, and where, as in the latter class of photography, the nearest prominent object may be hundreds of feet or yards away, a separation of three and a half or even four inches may be adopted.

It all comes to this: the nearer the object to the camera, the less the separation; the more remote the object, the greater the separation. We have known of stereoscopic photographs of objects placed immediately in front of the camera being taken with a separation of only one and a half inches between the lenses. On the other hand, instances may be recalled where, when stereo-photographing distant objects, yards have separated the objectives, and there is the well-known case of the binocular photograph of the moon, taken, so to speak, with the lenses separated many thousands of miles. Here we have the two extremes of the principle brought into force.

It is in the photography of objects placed near the camera that the value of being able to adjust the centres of the lenses chiefly asserts itself. Half an inch in the separation makes all the difference between naturalness or exaggeration of relief. It is the latter defect which offends so many of those who examine stereo-photographs for the first time. In nature, no matter how near an object may be to the eye, we are not conscious of its possessing exaggerated relief. The base-line of the parallactic angle formed by the eyes is approximately two and and a half inches. When, however, a stereograph of the same object, taken under conditions which lengthen the base-line to three or even three and a half inches, is presented to the eyes, it is not difficult to conceive that the mental impression so produced differs vastly from that which is the result of an examination of the original by ordinary vision. In the latter case we have the sense of reality; in the former, the impression of unreality.

We might extend this theme indefinitely. Sufficient, however, has probably been said to show that, when it is desired to take the fullest advantages of the power of making stereographs of objects situated very near the camera as well as those lying in more distant planes, adjustable objectives become something more than a convenience—viz., a necessity.—*British Journal of Photography.*

Of six thousand applications for letters patent for inventions in connection with cycles in 1897, only 2,300 were completed, a much smaller proportion than the average.

On June 1st last, automatic couplers and train brakes had been applied to over 60 per cent. of the freight cars in the United States. Of the 34,787 locomotives owned on June 1st, 32,426, or 93 per cent., are equipped with driving-wheel brakes. There are 211,268 freight-cars out of a total of 1,251,415, or 17 per cent., that are not equipped with automatic couplers; 552,696, or 44 per cent., that are unequipped with train-brakes, and 2,361, or 7 per cent., of the locomotives not equipped with driving-wheel brakes.

Technical Institutions, &c.—At this time the technical institutions and colleges begin their sessions, and we receive the programmes, &c. The City of London College, White-street, Moorfields, is excellently situated for the convenience of students from all parts of London, and the engineering department is under Prof. H. Adams. The Northampton Institute, St. John-street-road, E.C., is educational and social, and is now a polytechnic with classes in all trades, including those generally followed by women. King's College, Strand, London, has a special branch for architecture, building construction, &c., with both day and evening classes. The Borough Polytechnic Institute, St. George's Circus, S.E., has classes in a great variety of subjects, including the arts and practically all trades. The calendar of the famous Birkbeck Literary and Scientific Institution, Bream's-buildings, Chancery-lane, E.C., has also been received, and shows that the "Birkbeck" still holds its premier position as an institution where teaching in all branches can be obtained.

SCIENTIFIC NEWS.

THE meeting of the British Association at Dover seems to have been satisfactory to everybody, and the total attendance, judged by the number of tickets issued, was 1,403—not so many as might have been expected. A "notice" was given that at the meeting of the general committee next year at Bradford Prof. Hartog would bring forward a resolution dealing with the status of women in the Association.

Some papers on the ethnography of the Lake Region of Uganda, which may soon become of special interest, were taken as read, as they are to be published in full in the *Anthropological Journal*. Col. Macdonald's paper dealt with the tribes met with during the progress of the Juba (Macdonald) expedition of 1897-99. It gave details of 30 or 40 native tribes, their language, customs, and traditions, describing regions which were the meeting-places of several great African families—the Bantu, the Negro, the Hamitic, and the Massai or Nuba Fulla. Much information was given regarding their habits and customs, agriculture, marriage rites, religious beliefs, general organisation for war, fighting weapons, and knowledge of working iron, dressing hides, and making pottery, and the history obtained from their own traditions or deduced from those of their neighbours respecting their present and past geographical distribution was fully considered. A curious and interesting point was that all these tribes believed in one Sepreme Being—Ngai—and a future state. In Lieut. Pope-Hennessy's paper it was shown that the author had the opportunity of observing a number of West African tribes in the course of the expedition led by Capt. Lynch from Ibi, on the Benue, into the kingdom of Banchi. There were two roads from Ibi to Banchi, the more usual being by Waze, the shorter by Jibjil and Pongru; but the latter was rendered dangerous to caravans by three tribes of non-Mohammedan raiders—the Wurhu, the Zigori, and the Tangale—who in their native hills had resisted the advance of Fulah conquests. The paper contained many details of these three tribes, together with notes of the Jukos, another Pagan tribe said to have formerly ruled a large empire on the Middle Benue, extending from Banchi to the Allah-Katsena river, but now for the most part fishermen and canoe men in the district round Ibi.

In a memoir containing remarks on that presented by M. Flammarion to the Paris Academy of Sciences, which gave an account of the observations of MM. Antoniadi and Mathieu, of the Perseids of 1899 as observed at Juvisy, M. Bouquet de la Grye expressed the opinion that it would be possible to utilise shooting stars as a means of determining differences of longitude between places unprovided with the telegraph!

The director of the Marine Observatory of San Fernando, Spain, announces that the Minister of Finance has directed that all instruments to be used for the purpose of observing the Eclipse of the Sun on May 27, 1900, are to be admitted free of duty.

We record with deep sorrow the death of Mr. Charles William Bradley, the head of the firm of printers who for so many years have produced this journal. Mr. Bradley, who was in his 62nd year, died at Brighton on Sunday last, and was buried at Hove Cemetery yesterday amid the regrets of many old friends. Mr. Bradley sprang from an old Huguenot family, and his forbears settled in England during the religious persecutions of the seventeenth century, in company with their compatriots, so many of whom were identified with the silk-weaving industries. His early life was one of struggle and self-sacrifice, but he soon found his footing. He determined to be a printer, and, surmounting many difficulties, succeeded in apprenticing himself to the late Mr. Levy, the well-known proprietor of the *Daily Telegraph*. Shortly after the close of his apprenticeship—by which time he had already married—Mr. Bradley started in business for himself, and, in spite of some obstacles, was in no long time successful. In subsequent years the firm was joined by Mr. West, and the present flourishing business solidly built up and extended. In private life Mr. Bradley enjoyed the friendship of all who knew him. His principal recreation was music, and, had he elected to pursue that art in early life, his natural gifts would undoubtedly have secured him a creditable position among its votaries. One of the keenest and shrewdest men in business, he was a very faithful friend, and never missed an opportunity of assisting the less fortunate.

The death is announced of Mr. Edward Case, the "expenditor" of the Level of Romney Marsh, whose system of groyning has done so much in that district, and the success of which made his name well known not only in this country, but abroad, in places where it became necessary to stem the encroachments of the sea. He was at the meeting of the British Association, intending to read his paper on "The Dymchurch Wall and Reclamation of Romney Marsh," but was taken ill, and, returning to his residence at Dymchurch, died rather suddenly on Saturday.

It is stated that the passengers on the Royal Mail steamer *Trinidad* for Bermuda have had a curious experience. When about 360 miles from St. David's Head, Bermuda, an immense aërolite made its appearance, travelling from W.N.W. to E.S.E., and apparently was quite close to the ship. It looked to be a large megaphone (!). One-third of the body, from the base, glowed and sparkled like red-hot iron; the other two-thirds were of a brilliant shimmering green colour. Its path through the air was so well defined that it could be seen for several minutes after the body had disappeared, and it looked as if it had been marked out with whitewash. The aërolite appeared to be so close to the ship that those who saw it thought that when it fell into the sea it would splash the water on to the deck; but it proved to be at a greater distance than it appeared to be, and fell beyond the horizon.

Another Arctic expedition is to set sail this month for an exploration of the Samoyede region, and any other work that can be accomplished. It is the Jeaffreson-Chowne expedition, the leader of which is Mr. J. R. Jeaffreson. The party is to go to Archangel, and, as soon as conditions permit sledge travelling, will proceed to some of the most unknown parts of Siberia. Part of the distance from Archangel will be covered by steamer if the ice is not firm in Kara Straits. The idea of the expedition is not so much to reach the Pole as to explore unknown districts in the Samoyede Peninsula, and observe manners and customs of the natives and make scientific observations. The explorers are taking a large stock of guns and ammunition, as they hope for excellent sport.

The lectures to be delivered on Tuesday evenings during October at the Royal Victoria Hall, Waterloo Bridge-road, will be:—"The Value of Nitrogen," by Prof. Holland Crompton, F.R.S., on Oct. 3; "Liquid Air," by Prof. W. Ramsay, F.R.S., on Oct. 10; "Source and Course of the River Thames," by Dr. C. G. Cullis, on Oct. 17; "Photographs taken in the Dark," by Dr. Russell, F.R.S., on Oct. 24; and "Kamschatka," by Capt. Barrett Hamilton, on Oct. 31.

It is announced that the lighting of the Batignolles tunnel, near Paris, will be done by lines of 10c.p. incandescent electric lamps, placed about a mètre apart on the walls of the tunnel, and ranged at the level of the windows of the trains. Thus if a train has to stop in the tunnel the compartments are lighted from the outside; but economy is studied by making the lighting "automatic," the running of the train over levers or plungers turning on the light.

An interesting antiquarian discovery is reported off the East Coast, at Sandlemere. During the low tides the ebb has been assisted by persistent favourable winds to such an extent that large tracts of coast have been left bare and cleared of shingle, so as to expose the parts for observation, with the result that the habitat of an old-world colony of lake-dwellers has been revealed. The old piles are standing, and the rough-hewn tree-trunks of the platforms are still there, showing the tool-marks and evidences of mortising and jointing. Another colony of lake dwellings is already known to have existed near by; and it would seem from this new discovery that there must have been a considerable number of them in prehistoric times in that district.

A Deal fisherman is reported to have recently landed a lobster weighing not less than 8lb. 2oz. The body is 17½in. long, while the right claw measures 17½in. in length, 5in. in breadth, and 13½in. in circumference. The lobster is said to be a record for Deal.

It is stated that a File-fish (Balistes capriscus) has been landed at Mevagissey and forwarded to the Marine Biological Laboratory Plymouth. According to the descriptive account the "creature" was about 16in. long, 8in. deep, and weighed 2¼lb. It is not unlike a John Dory in form and colour. The last of this species known on the coast of Cornwall was caught in a crab-pot off Portloe, and the late Dr. Couch, of Polperro, sent it to the British Museum in 1865. The fish is known in the Mediterranean, but is scarce there, and was deemed injurious to the pearl fisheries in those waters. The first recorded British example was caught off the coast of Sussex in 1827. Of its habits there is little known more than with its strong teeth it is able to break through the shells of mollusks and eat thom as food.

The following rather extraordinary statement is made in the *Industrial Advocate* (Halifax, N.S.):—A process for making fine wool from the limestone rock found in such inexhaustible quantities in the neighbourhood of Alexandria, Ind., is a recent discovery by C. H. Hall, chemist of the steel works at that place, the claim being that, from a combination of 94 per cent. of the limestone, chemicals, and one of the commonest of minerals, pure wool is obtained as white as snow. It seems that, while making experiments with limestone for his factory, it was found that a certain kind of material, instead of turning to quicklime when subjected to fire, would, when combined with chemicals, turn into lava, and when subjected to another process; this lava could be rendered pliable and handled like molten glass. From this beginning the process was pursued, and a downy wool resulted, with promise of considerable industrial possibilities—that is, such rock wool is represented to be as soft and white as that produced by sheep, and can be manufactured cheaper than sheep can be raised and clipped, is not affected by fire or water, and the supply seems to be almost unlimited.

USEFUL AND SCIENTIFIC NOTES.

THERE are sixteen dockyards along the coast lines of Japan.

THE rapid destruction of the spruce forests of the Eastern States of America may be realised when it is understood that one daily paper used the growth of 22 acres in two days, the wood having been reduced to pulp and then turned into paper.

ON the Royal farms in Prussia some experiments have been carried out with electrically-driven ploughs. The cost of electric ploughing was said to range from £2 6s. to nearly £3 per acre, while the cost of steam ploughing came out at considerably over £4 per acre. These figures are for ploughing heavy soil to a depth of 8in. to 10in. The speed of the plough was about 3ft. per second.

THE coal industry of Western Australia is developing rapidly. With the deepening of the mines a better quality of fuel is being mined, with the result that it is not only being used largely for domestic, mining, and railway purposes, but also by local steamship companies. This coal, it is said, is likely to be of very considerable value. It burns somewhat quickly, giving out much heat and leaving a small percentage of ash. An authority reporting on it says that, although it cannot be put into the first class, there can be no doubt that it will prove a valuable fuel. As a steam raiser it is greatly to be preferred to many other coals of better composition which produce much smoke.

The Permissible Rise in Temperature in Electrical Apparatus. — The committee on standardisation of generators, motors, and transformers, appointed by the American Institute of Electrical Engineers, have reported with regard to the permissible rise in temperature of electrical apparatus. The standard temperature and pressure selected for reference are respectively 77° Fahr. and 29·92in. of mercury. If the room temperature during the test differs from 77° Fahr., the observed rise of temperature should be corrected by nine-tenths per cent. for each degree Fahr. to make up for increased copper resistance. A full-load run of from six to eighteen hours is recommended before making temperature tests, but this can be shortened if the machines are heated up by overloading them. The rise of temperatures of conductors should, it is recommended, always be measured by their increase of resistance. The increase for copper is taken at seven-tenths per cent. per degree Fahr. With this method the maximum rise allowable is given at about 90° Fahr. The other parts whose temperature is measured by thermometers are allowed somewhat more, with the exception of the bearings, where 104° Fahr. is the final maximum.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

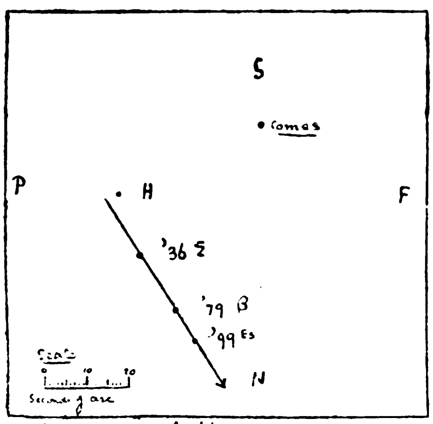
"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

α LYRÆ—ε LYRÆ—A NEW STAR OF TYPE IV.—THE NEW EDITION OF ARGELANDER'S ATLAS.

[42873.]—IN answer to Mr. Ellison's request, I looked up α Lyræ on Sept. 2 and Sept. 4, and failed to find any *comes* nearer than the well-known 10·5 magnitude. The pair is an optical one, and the little *comes* is rapidly being left behind. I ran the micrometer wires over it, and got—

P = 162·8°. D = 54·3″. 1899·67.

The following diagram shows the motion of the large star since H's time, whose distance would



Motion of Vega

seem to have been too small. I do not know the date of H's measure.

While showing ε Lyræ to a friend the other evening I noticed a star fainter than the *debilissima*, and careful attention revealed two others. They were all seen in moonlight, and I have run the micrometer wires over them roughly, all except No. 5, and made the inclosed drawing to scale, with

ε¹ and ε² Lyrae

the exception of the close pairs, whose distance is exaggerated. I have had so little experience with the micrometer, and my apparatus is so rough, that it is hardly worth giving the individual measures. Nos. 1 and 2 are the *debilissima*. The following are my estimations of the magnitudes to-night:—

No. 1 ...... 11·5	No. 4 ...... 13·5
No. 2 ...... 12·0	No. 5 ...... 14·0
No. 3 ...... 13·0	

May I say how glad I am to see that the interest in these old-fashioned objects is reviving in your columns? Now and again when I can spare a little time for star-gazing from the regular routine work, it is a great pleasure to look up old friends that one has never seen for years. Years ago there was much correspondence over ε Lyræ in these columns, but I do not remember if these faint stars were ever laid down in a diagram. I hope some of your readers may look them up and report what they can do with them. A younger and keener eye may perhaps catch other faint points; but I have laid down all I can actually feel certain about.

Stars of Type IV. within the reach of my instrument that have not already been detected are now very rare. On Aug. 11 I, however, swept up one which has hitherto escaped detection. It is B.D. + 53° 2736 21h. 49m. 56s., Decl. + 53° 49′ for 1855, mag. 9·0. I made it 8·6 Aug. 11, and Sept. 14, 8·7. Its magnitude is given in the Harvard zones:—

1874, Oct, 22 .... 8·7
1883, Oct. 11 .... 9·2

It is curious that it has escaped detection so far, if it is not, like so many of this class, variable.

Is it generally known among your readers that the great Atlas of the Heavens of Argelander has just been republished at Bonn? I mention it because for stellar work it is simply invaluable.

T. E. Espin.

Tow Law, R.S.O., Co. Durham, Sept. 14.

METEOR.

[42874.]—A BRIGHT meteor was seen here at 9.55 p.m. on Saturday, Sept. 16. In the bright moonlight it appeared about four times as bright as Jupiter. It came from the direction of Capella and passed through ζ Herculis. It was remarkable for the great length of its path (about 80°), which it traversed at a great rate of speed. It left a short streak.

St. Alban's. **G. S. H.**

THE COMET AND THE DELUGE.

[42875.]—MR. F. H. WENHAM is quite mistaken about the Deluge story being invented by believers in a flat earth (letter 42851, p. 136). No universal flood on a flat earth was conceivable. It required mountain barriers to confine the water, and the only way Noah or any animals could be saved was by moving to those mountains. The device of a floating ark really implied a globular earth. I do not mean that either Noah or the writer in Genesis knew the earth to be globular. But the story (if invented) was invented by those knowing quite as well as Newton or Halley its roundness. On no flat earth could it be half so easy to construct an ark as to escape to hills not flooded.

Another common mistake is that Genesis implies no beasts to have been saved but in the ark. But in chap. ix. 10, God makes a covenant with mankind and the animals, from those that leave the ark *to every beast of the earth.* The rainbow, which probably Noah's family had never seen before, having dwelt in rainless Upper Egypt, was made a sign of this covenant. The cataracts of rain had swept off all vegetation, uprooted all timber, and left bare hills only. The best illustration left of their violence is the way they filled bone-caves with the bodies of most discordant beasts, hyenas, wolves, and bears, with sheep, and occasionally human bones. These caves have been found in every European country, and in Asiatic, African, and those of both Americas. But the cataracts having lasted only six days (according to Hasisadra's account), it was quite possible for many of those creatures that clung to the drifting timbers and landed to find food. In less than six months a young olive sapling yielded a leaf to the dove. But saving of men in another week from the catastrophe, as Hasisadra implies, was quite impossible. Genesis implies all wild nature, vegetable and animal, away from Armenia, to have had nearly a twelvemonth's start of Noah and his cattle. These were taken in November from the hottest parts of the old world, and having grounded, they were hoisted up above the clouds, to pass the summer imprisoned till the next November, in the coldest climate of this renewed and warmer world.

It is astounding to think of Samuel Graham Wilson living 15 years at Tabriz as a missionary, leaving the timbers Nouri had found, as *deceiving* somebody. Whence on earth does he suppose them brought to the snow, 15,000ft. above sea-level? What was he a missionary of? Seemingly of Prof. Bonney's creed, or the anticatastrophist Lyell, before he tumbled down and broke his neck.

In quoting the missionary Wilson (p. 39), I was quite aware that his first story about Mount Ararat was a blunder. I only meant to refer to Nouri's in 1892. It is not clear to me that the statements in Psalm cxiv. quoted by "F.R.A.S." in p. 133, are mere poetry. The Psalm describes the earthquakes that accompanied the exit of the Israelites from Egypt, when there was an eruption of Sinai, and as Psalm xcvii. says, "The hills melted like wax at the presence of the Lord." All this may be "statements of physical fact." Again in p. 134, answering query 96601, surely an eye at sea-level can see hills 60 or 70 miles distant, if they are high enough. They must be 2,400ft. to be seen at 60 miles, or 3,267ft. at 70 miles.

E. L. Garbett.

THE DELUGE.

[42876.]—REFERRING to the criticisms passed upon my letter of August 11, contained in your two following numbers, I would firstly say that it is inconceivable that heathen nations can have been influenced by Christian missionaries to believe and narrate the story of the Great Flood, and sometimes of the Fall of Man that preceded it, without being influenced by them also to believe and narrate something about the Saviour Christ and His doctrine. Yet there is the tradition running all round and all over the world among nations and tribes that show no traces of Christian doctrines or observances, or of Jewish ones either, or even of those grafted on Judaism by Mohammed.

I omitted in my former letter to say that when I asked Mrs. Isabella Bird Bishop, who has spent thirty years of her life in travelling over Asia in all directions, whether she had personally come across legends of the Flood among Asiatic people, her answer was: "They all have it." And similarly, when, in 1896, I told Mr. J. Owen Dorsey, who the year before had presided over the Anthropological section of the American Association, and has written learnedly upon divers Red Indian tongues, that I had just read in verse the Ojibway legend of Nanabusha, who restored the dry land and its inhabitants, both men and brutes, after all had been swept away by a flood, he said in reply: "I meet with the same story among all the Indian tribes."

Now, Humboldt records in his book upon the Orinoco that the traditions of the Deluge existed among the Tamanacs and Maypures and many other tribes in that region, although upon careful search (as I have read in the said volume) he could find no fossil-bearing strata that could have given origin to the tale, and these tribes, as he tells us, claimed descent from one man and one woman who were saved on the top of the mountain called *Tamanzcu.*

Again, Pastor Böressen in 1876 was giving an account to a Free Church folk of Aberdeen of his mission in company with two other evangelists to the Santals (an Indian hill tribe), begun ten years before, when they had never heard a word of the Gospel, and were cut off by language and manners from all intercourse with Europeans, and I heard him tell two primitive traditions of this people. Their first parents, said they, were placed in a most beautiful garden by the spirit of good; but the spirit of evil came and tempted them to partake of a forbidden drink. They yielded, and were punished by being driven from the lovely garden to dwell in the outside world. Time went on, and men became very numerous, but also great sinners. The spirit of good in anger destroyed all but seven men and seven women, who escaped in a boat, and became *the progenitors of the Santals.* Again, Hugh Miller, the eminent geologist ("Test. of Rocks," p. 288), among other legends of the Flood, quotes one from the Scandinavian Eddas as follows:—On the death of the great giant Ymir, whose flesh and bones form the rocks and soils of the earth, and who was slain by the early gods, his blood, which now constituted the ocean, rushed so copiously out of his wounds, that *all the old race* of the lesser giants, his offspring, were drowned in the flood which it occasioned *save one;* and he, by *escaping on board his bark with his wife,* outlived the deluge.

Now, in the first story, the fact that those Brazilian tribes give the name of the mountain of refuge as identical with one of their own names shows that they could not have borrowed the story from a Christian or Jewish source; and so, too, the fact that the Santals declare themselves to be the descendants of the saved pair proves that the tradition is a native primæval one. And, taking the three legends together, unaccompanied as they are by the least trace of the distinctive tenets or ceremonies of either Christians or Hebrews, and prevailing among nations far removed by language and space for long ages from both, the common pith of each legend must have been handed down from a time when Brazilians, Santals, and Norsemen all dwelt together. But this is a time of which the Bible alone succinctly tells us, as part of a consecutive history (though it is borne out also by the cuneiform tablets) when all men were in Shinar and Mesopotamia. And how, even then, could they have communicated the tradition of the Deluge to one another, unless the Bible record (borne out by the tablets again) is true—that then all men spoke the same language? And is it conceivable that this is true, and yet that the story of the event which the Bible just previously records is untrue?

For this, we should have to suppose that after punishing men for their sin by confounding their languages, and sending them forth as different nations over the earth, the Creator at the same time caused each nation to treasure up a lying tale of a previous transaction of His with the children of men.

The supposition needs only to be stated in order to be scouted. The facts stand thus: The Hebrews alone possess a consecutive history, giving many genealogies and dates, interspersed with not a few events, from the Creation of Man down to the founding of their own nation, and onwards, in the course of which (with the date after the Creation of its beginning and end duly assigned) comes a succinct account of the Flood; but legends preserved by a host of nations all over the globe (possibly by all nations if due inquiry had been made) preserve the main features of this account, and some of them—as the Babylonian and Brahmin one, for instance—many features besides. The conclusion in every reasonable mind, therefore, should be that the story contained in the Hebrew scriptures is true, even if we were not assured of the fact, as we are, by its being used as a moral warning and example both by the Apostles and by the Divine Saviour himself. All scientific facts, therefore, which now seem to conflict with it must ultimately be found to harmonise with it, and in your own columns I, for one, am indebted to Mr. Leonard Kelly for his summary of facts that confirm the solemn story, as well as for pointing out that Noah had not to collect all the animals small and great which he stowed in the Ark, but that God planted an impulse in them to "come" to him. (Gen. vi. 20.)

The objections to a universal deluge—that is, to one covering the whole globe—are strong, but, I do not think, invincible. For instance, as regards the number of species carried representatively by twos, and now and then by fourteens, we must remember that birds and clumsy beasts, such as monkeys, squirrels, racoons, and opossums, would have occupied little lateral space, for cages could have been found for them no less than 20ft. high between any two of Noah's decks, and perches duly ranged about and all the way up the cages, just as in zoological gardens nowadays. And, again, the species, though numerous, may have been far less so than now. An Eskimo dog is not distinguished from the wolf, with which it freely plays when out of harness, as I have heard an Arctic explorer, Mr. Stupart, tell the Canadian Institute. At Winnipeg, the chief warder of the prison, who so wisely preserved a remnant of the bisons a few years back, found that they freely interbred with domestic cows and bulls: and the experiments now being conducted by Prof. Cossar Ewart in Edinburgh tend to show that the domestic horse and the zebra had a common ancestor since the creation of man (*Westminster Gazette*, July 18, 1899).

But, after all, the safest course to take is that of Hugh Miller's, and hold that the Deluge extended no further than the settlements of men. This does no violence to the language of Holy Writ; for why should the statements of Genesis vii. 21 and 19 (R.V.), "All flesh died that moved upon the earth," and "All the high mountains that were under the whole heaven were covered," be more comprehensive than those of Genesis xli. 57, "All countries came into Egypt" to buy corn, because the famine was sore in all the earth, and of Deuteronomy ii. 25, "This day will I begin to put the dread of thee and the fear of thee upon the peoples that are under the whole heaven"; or of Acts ii. 5, "There were dwelling at Jerusalem devout men from every nation under heaven?" And considering that three hundred million Chinamen were content up to the beginning of this century to dwell without emigration inside the bounds of China, why should the habitats of the human race before the Flood, who probably after 2,000 years of growth were less numerous than the Chinese after 4,000, have been more extensive than Russia and Turkestan united, where Hugh Miller places them, a territory several times as large as China?

He points out that around the Caspian Sea are "vast plains white with salt, and charged with sea-shells"; while the shells also "abound in an outer region, which includes the vast desert of Khiva," and I would add, on the authority of Sir William Dawson, in his "Meeting Place of Geology and History," that shells have been found on the surface of the Pamir Mountains up to a height of 15,000ft. The first-named geologist also points out that this whole region lies low, while some of it is completely beneath the level of the ocean, and therefore it would be the more easily depressed to a point where the ocean would completely cover it. The flowing in of the waves along the river valley would indeed be a "breaking up of the fountains of the great deep."

The geographical description given of Eden in the Bible and on the Babylonian tablets compels one, however, to add Turkey in Asia at least to the antediluvian settlement of men; but otherwise the great geologist's theory seems without a flaw. And if in the present century we have seen thousands of square miles at a time in the estuary of the Indus in 1819, and in western Java in 1883, drop low beneath the waters, and have observed a vast region like Scandinavia year by year rising on one side and sinking on the other, what is there contrary to reason in believing that at one time the Almighty, because of the sin and ingratitude of His creatures, caused the whole vast region we have named to subside for forty days in succession, concentrating all His rainstorms upon it at the same time, until all the mountains within it were covered with a watery waste?

Mr. Dormer talks slightingly of the attempt made to prove an affinity between the cuneiform letters and the Chinese. I therefore repeat more succinctly that Prof. Lacouperie showed to the Philological Society of England, when I was present about seven years ago, some fifty letters of the cuneiform and as many of the Chinese alphabet before this was made ideographic, and the resemblance was very striking. It does not militate against this connection that the Chinese carried with them neither of the Babylonian languages, the Altaic, Accadian, or the Semitic Sumerian (an Aryan language no one but Mr. Dormer has hitherto credited them with). The Bible tells us that all nations once lived around Babylon before the confusion of tongues; and the Babylonians, who have themselves a tradition of this confusion, say, on the other hand (as I have shown), that books were always known to mankind; therefore it is well-nigh certain that this cuneiform writing existed before the confusion of tongues, and that the Mongols and Chinese—the sons of Magog—took it away with them when they migrated to the east.

But Mr. Dormer, who is very fluent in the language of contempt for others, is himself rather prone to tumble into pitfalls, for I notice that in the same letter he talks of the "philanthropic partnership scheme" ascribed by Mr. Garbett to "Rameses the Great and his much beflogged fellaheen"; whereas Mr. Garbett ascribed the partnership to an Egyptian sovereign who, by any reckoning, reigned at least 150 years before Rameses the Great—the Pharaoh who welcomed Joseph's brethren, not the one who first oppressed the multitude of their descendants.

However zoology and geology may appear to be against the universal deluge, I by no means agree with Mr. Dormer that either anthropology, philology, or archæology is against either a partial or a universal deluge. Archæology, as embodied in the traditions of the people of the world, is all in favour of it. Philology shows savage nations, like those of North America (in the teeth of Dean Farrar's absurd theories), to be possessed of languages utterly different from those of the literary nations, yet extraordinarily rich in expressiveness and grammatically synthetic. How came this about, unless their ancestors at Babel were endowed with a fresh and perfectly formed language?

Again, as regards anthropology, the table of nations and their parentage given in Genesis x. wonderfully tallies with ancient ethnography. Take two instances only. Genesis x. tells us that Japhet, one of the very few human beings who had survived from a previous age, had a son called Javan, by whose children "the isles of the Gentiles were divided." The Greeks, on the other hand, tell that their earliest human ancestor was Japetos, a son of Heaven and Earth; while Homer commonly calls the rank and file of the Greeks either Argeioi (Latin, Argivi) or Jaones (with the digamma, Javones). [Compare Smith's "Classical Dictionary" and Gladstone's "Treatise on Homer," pp. 102 and 103.]

Again, the same Bible record states that Ham (in Hebrew Kham) was the father of Mizraim, or the Egyptians as well as of many other African peoples (compare with Chap. I. 11). The Egyptians, on the other hand, worshipped a god called Kham; they had a very ancient city called Khemmis, and they called their country Khemi. And now in modern times the Matabele have a river called Kami, and a tribe called Kamm; while there is no commoner name among the Kaffirs than Khama, which has been rendered so illustrious by a Bechuana chief. (See Chambers's "Cyclopædia," Smith's "Class. Dictionary," &c.) **Martin Luther Rouse.**

THE MOSAICAL DAY.

[42877.]—"F.R.A.S." seems to imply that I invented it all, simply because he is not acquainted with the subject. What he calls "wild nonsense" is a rescript from M. Delambre's work on "Ancient Astronomy," in addition to recent translations of Assyrian tablets. My deductions as to the possibility of Moses applying this Cosmic Day in his record, is, I think, worthy of consideration; to suppose that each successive creation occupied 24 hours is "nonsense" indeed.

73, Clarence-road, Clapton. **J. D. Hardy.**

THE DAYS OF CREATION.

[42878.]—THE earth rotates on her axis in 24 hours *now*; but the "evening and the morning" were not always of the present length. The friction of tides is constantly lengthening the day, and as this has been the case from the beginning, Prof. Darwin proves that, when the moon originated, the day and night were about three hours, and the month the same. Both day and month have lengthened, and the ratio between them became rather greater than we find it now. The number of days in a month is now diminishing, the day lengthening rather faster than the month.

The days of creation in Genesis are very long periods, as everyone must have seen, before St. Augustine or even the New Testament. The order of the words "evening and morning" showed this; because "evening and morning" do not begin and end in a day, but a night. A recent translation I have seen, in these terms: "and there were evenings and mornings one day." Afterward, "There were evenings and mornings a second day." And so on up to "a sixth day." The phrase occurs only six times, for there is no such statement about the seventh day, because that is incomplete. We are still in the seventh day, which began by Noah's flood. In the seventh creative day, God rests or desists from His creative works, and is refreshed.

Light being created, times of light were distinguished from those of darkness and called days, the dark intervals being nights. Now we find the earth as a whole is no darker at one time than at another; but she is liable to encounter comets, which, when falling, must darken her entirely. Are not these, then, the nights between days of creation?

The Hindoos reckon days of Brahma of something like 432,000 years divided by comparatively very short nights. The days of creation may have been such periods, not equal, but marked off by comet-falls. The statement in Genesis is that "evenings and mornings" have endured through all these periods. The new world that appeared in the Andromeda nebula in 1884, if it rotates, must have evenings and mornings just like our earth, although it has no sun. Every part has day when turned towards the central nebula, night when turned away. It is in the exact condition that Genesis describes our world in the three first creative days, before the sun or moon existed.

Sept. 23. **E. L. Garbett.**

THE NO. 666.

[42879.]—IN reply to "E. L. G." (p. 140, 42370), the passage referred to, in Daniel viii. 25, is "He . . . . by peace shall destroy many." In the "Teacher's" Bible, and several others which I have consulted, the margin gives *prosperity* as an alternative reading for *peace*. Is not the same "Beast" referred to? **Glatton.**

THE ORIGIN OF SPECIES—SIR MICHAEL FOSTER'S ADDRESS.

[42880.]—I WOULD remind Mr. Garbett (42815 p. 115) that Darwin's "Origin of Species" is not nearly so absurd as the fabulous story he is trying to bolster up—"The Deluge."

Assuming (42869, p. 140) that "the first man, the first ox, or the first of any new species originated. . . from a virgin," we have still to ask, Whence the virgin? I presume the virgin is of the same species she is to originate.

It is an astounding piece of information that Mr. Garbett has given us in stating that the *sun is younger than the earth*. Of course, this miserable, third-rate planet was created first and the rest of the universe afterwards. I can give Mr. Garbett some more information like this: (1) There are mountains on the moon; (2) Neptune is the furthest planet from the sun yet discovered; (3)—— But enough. I will write seriously, although it is hard to take Mr. Garbett so.

It is not certain that the earth is the densest planet. More probably the moon is. Therefore, theorising from Mr. Garbett's standpoint, the moon is the oldest. It is understood, of course, that we are dealing with the Solar System only. There are probably immense dark stars distributed through space, beside which the earth is a mere satellite (which she is, of the sun). Few people who have seen a variable star can doubt this. It would be interesting to have Mr. Garbett's views on the Nebular Theory.

Because a star in the Andromeda nebula blazed out suddenly, and then disappeared in six months, does not prove that it cooled down in that time. I consider it highly improbable that a star can cool down in six months, or six thousand months if you like.

Erratum: In No. 42840, line four from bottom, read "faintest" for "greatest."

Earlsfield, S.W. **Silverplume.**

THE VITALITY OF SEED — VISUAL CONCEPTS—PARTHENOGENESIS.

[42881.]—I AM obliged by "F.R.A.S.'s" assurance that no wheat from mummies has germinated. As the vitality of seeds is very variable, it would be of interest to know the greatest age at which such a proceeding has occurred. I believe legumes have been shown to retain their vitality longest, and it is well known that willow seed is very short-lived.

One sometimes idly speculates on the possible influence of the vitreous humour of the eye in connection with conceptions due to vision. Sight, of course, results from the action of light on the retina, the other contents of the eye-ball merely rendering objects perceptible. It is curious that the jelly-like vitreous humour, firmly compressed by the orbital muscles, bears a certain resemblance to the conception of ether.

Theories supported by ill-invented "facts" and abuse of eminent scientific men simply provoke laughter. The slangwhanging of Darwin and Lyell with boomerang epithets that only harm Mr. Garbett is very suitable sauce for his hash of science. As to letter 42869, the possibility of a woman bearing a child whilst retaining a deceptive virginity has nothing in common with the production of young without male assistance, which occurs in aphides, crustaceans, and other lowly forms of life. If Mr. Garbett had troubled to read Chapter XIV. of Darwin's "Origin of Species," he might have become aware that parthenogenesis has not been discovered "since Darwin's time." As a matter of fact it was observed in 1701 in the silk-moth, and in 1745 Bonnet described the successive generations of the virgin aphides; indeed, Owen's work on the subject appeared a decade before the "Origin." There being no record, I believe, of any new animal or vegetable species produced parthenogenetically, this notion provokes the same derision as those concerning the age of the sun, watery comets, *et id genus omne*. It tempts one to echo the plaint of Sterne's abbess: "Oh! virginity—inity—inity!"

J. Dormer.

CAPITAL AND INTEREST.

[42882.]—I AM still at a loss with regard to Mr. Garbett and his ευπορια. He evidently knows more about Demetrius than I do—or, I think, than Luke did. As to the relations between Demetrius and his workmen, in fact, Mr. Garbett is my sole source of information; but I think it very unlikely that the writer of the Book of Revelation had this passage of the Acts of the Apostles in his mind when writing, and, in fact, it is not improbable that the Acts of the Apostles was written subsequently to the Book of Revelation.

I have not read Mr. Ruskin's views on the subject, and I cannot promise to read them. With regard to the relative merits of our system of land tenure and the Metayer system, I should think that Carlyle did not follow them far enough to ascertain experimentally that one led to heaven and the other to hell; and, in fact, there would be a difficulty in transporting the land to either locality, or in carrying any system of land tenure without it. But the Metayer system appears to lead to more poverty than the system of fixed rents. What, however, are we to do in Ireland in order to avoid worshipping the Beast? The rents are fixed by the Court at a figure of which both landlord and tent may disapprove; and even if both parties asked to have the rent fixed as a share of the produce, the court would not do it.

Mr. Garbett tells me that the servants in the parables of the Pounds and the Talents were not employers of labour, though they were traders. I have had a good deal to do with traders, and in almost all instances I found that they were employers of labour—a remarkable fact being the frequency with which they raised the salaries of their servants when about to go into bankruptcy. Does Mr. Garbett keep a servant-girl? If so, is her salary fixed on the partnership principle?

With regard to the National Debt, I do not see why, if we execute some great work (say the construction of a railway) which is certain to benefit our successors, should we bear the whole cost of it and leave it as a present to them?

Might I suggest, as a possible explanation of Ahaz's dial, that the dial was badly constructed, or that the ground sank? **W. H. S. Monck.**

DOWN "CORNISHMAN," G.W.R.

[42883.]—As a companion to the up "Devonian" run on p. 15, I send a log of a run I took in the down "Cornishman" (summer part) running from London to Exeter without a stop. Unfortunately, since the train was rather heavy (one of the eight corridor coaches being a dining car), a stop was made at Taunton for a pilot engine (No. 1366) up the Wellington bank, and again at Whitehall sidings—the summit—to take off the pilot. In spite of these delays, costing $10\frac{1}{2}$ minutes, the arrival in Exeter was not more than four minutes late, for which the driver (Westbury) and the fireman both deserve praise.

To obviate the necessity for the pilot stops, the company have lately been using the large four-coupled "Barrington" class on this train. I give below a somewhat detailed account of the run:—

DOWN "CORNISHMAN."

London to Exeter, August 21st, 1899:—

Engine: 7ft. $8\frac{1}{2}$in. single bogie "Lord of the Isles," No. 3046.

Train: Seven corridor "eights" and one dining-car "eight" equal 180 tons behind the tender.

Weather: Fine, dry, and hot—calm.

Delays: Slowed through Bathampton and stopped at Taunton $2\frac{3}{4}$min., and at Whiteball $1\frac{1}{6}$min., besides the booked checks past Reading, Didcot, Chippenham, Bath, and Bristol; time lost = 24 minutes.

Actual time for journey, 226min. 40sec.; speed = 51·4m.h. Running time for journey, 222min. 45sec.; speed = 52·3m.h. Net time for journey, 202min. 40sec.; speed = 57·4m.h.

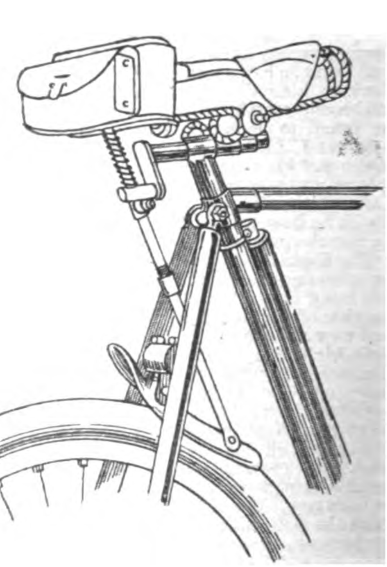
Flying average: Southall to Cowley Bridge Jn., 183 miles 46 chains, in 187m. 39s. (nett time); speed = 58·7 miles an hour.

Maximum speed: 72 miles an hour through Dauntsey.

Ealing, W. **O. R. Walkey.**

BICYCLE BRAKE.

[42884.]—IN last number of MECHANIC, at p. 124, is an illustration of a bicycle brake, called Cole's. There appears to me to be considerable merit in the idea, but it has one defect which may be easily



remedied, and I venture to inclose tracing, showing the improved position of the brake, going with the travel of the tire instead of against it, as well as giving a neater appearance, and making it easier to fit mudguard. **H. J. Burton.**

Southfield End, Uxbridge-road, Hanwell.

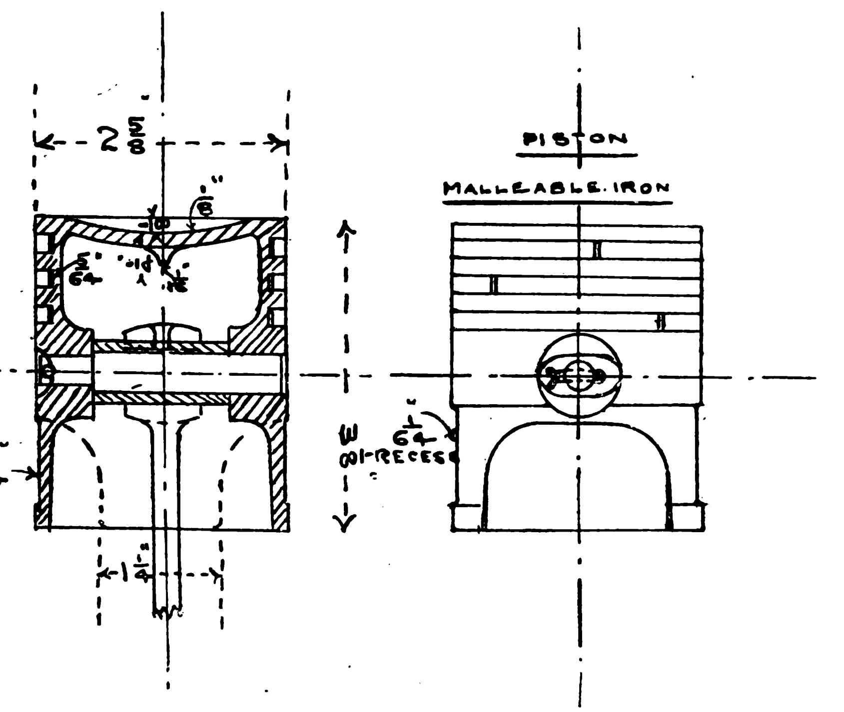
MOTOR-CYCLES.

[42885.]—As the former letter of mine on "Ariel Motors" has been replied to by so eminent an authority and expert as Mr. Chas. Sangster (p. 138), I think there are one or two questions raised in his letter to which an answer is needed.

The public will be gainers for the knowledge imparted by these discussions, and will, no doubt, make use of it when picking out a motor at the next show. Still, "when doctors disagree, who shall decide?" Every mechanical work brought out nowadays is fully commented upon by writers to the various technical journals, and good and bad points impartially reviewed. Readers have the option that they can hear both sides, and believe neither if they are so inclined. Perhaps I can convince even Mr. Sangster that some of the points I have criticised may be improved upon. "Every inventor is apt to look upon his goose as a swan," and therefore must prepare some time or other to find it thought otherwise. He replied to a former letter of mine on "Dion Motor," which was copied from "E. M." by the *Auto-Motor Journal*, and will, no doubt, remember all that was mentioned in that article.

I have looked up all particulars I possibly could about each motor I have so far described, and have gleaned further information from careful inquiry, and am therefore in a position to substantiate any statement I may make. I take the Dion as a standard figuratively, as it is so well known, and therefore serves as an object of comparison. As regards motor in front of back axle, I will obtain some particulars for you of them, and forward to address you have given; but you need not go so far as France. I may tell you twelve months before a single Ariel tricycle was made, Accles, Ltd., of Perry Bar, had one running on road with engine in front. This was illustrated in *Auto-Car* of Aug. 26.

The bearings I find, roughly speaking, contain 9sq.in. in the Dion, 9·6 only in Ariel; whereas proportions of latter engine being much larger, and a greater pressure on piston (which, I believe, is the guiding factor in designing all parts), the length of bearings should also be greater. Increasing the diameter to gain surface area is not good practice mechanically, as friction is greater with the larger



diameter and shorter bearing, which is not so well adapted to retain oil under pressure.

True, the bearings are ⅛in. closer between inside than Dion, but this cuts down width of the most vital bearing—viz., the big end of the connecting-rod; here you may look for squeak and trouble after hard running. Top or crosshead bearing in piston is, I find, even less in length than Dion; whereas it might be made ¼in. longer with beneficial results.

See sketch of piston sent last week for further improvements, which, if any good, adopt; if any objections, shall be pleased to hear of same. "Valve foot being inaccessible"! I maintain I am correct; if, for instance, foot comes off rod, or the latter breaks at lower end of guide bush, as I have known them to do, what advantage is bush then, as you must perforce take engine out and get it apart to recover broken piece.—Q. E. D. As regards Mr. Stocks's breakdown, I will quote a remark made by Lincoln, who said, "You may fool all the people for a time, or part of the people all the time, but you cannot expect to fool all the people all the time." I *know* what happened, and should advise the fitting of a split taper pin, as used on loco. work, in lieu of plain taper pin, through sparking cam. This would prevent any danger of spindle working through into crank case, and allowing head to get sheared off by the crank.

This crank, by the way, seemed to me a most expensive, complicated affair as compared with simple arrangement of Dion. Look at expense of making or repairing which would face an unfortunate rider. Might I suggest you could simplify it, using wheel on one side similar to Dion, making crank-pin and taper to fit wheel, also do away with pinion screwed on, and place on taper. If engine got jammed, look at pleasant "biz" of dropping it right down till pinion was out of gear before you could unscrew it, and what is to hold engine from turning while unscrewing pinion? It's sure to happen as soon as a few get on road; that would condemn design right away.

You will wonder how I am so familiar with internal economy of engine; but I have been allowed to see one taken apart, and took particular notice of all good and bad points for future reference. I regret I am going away for awhile, and cannot go further into the matter with you, both from personal and business reasons, though I am not in the motor-tricycle business, but speak and write from a rider's point of view, as an ardent rider myself. A two-speed gear is necessary, and I hope to give readers sketch of one when I can get time. There are no hills in Midlands of any great length or steep gradient; so don't base your estimates of way tricycle behaves on these roads.

I am right about furious driving, for, in papers lying before me, I find both yourself and Mr. Stocks largely figuring in police reports, in which they give what must be to you most gratifying and eloquent descriptions as to speed you were travelling.

All the clutches I have seen so far on motors, with one exception, possess the great fault that they are too small in diameter, and not properly constructed, being usually two cast-iron cones with long taper. For a tricycle they should be nearly 1ft. diameter, the inner cone having a bearing only about ⅝in. wide, composed of strips of leather on edge, working against outer cone of cast iron. I am aware it is a difficult matter to fit one calling for something better than mere copying in the designing; the greatest difficulty is to avoid the oil getting on it in excess;—if this was attended to clutch would give no trouble at all. I have lately seen one similar to one I describe that has been in use daily for months past, that is highly praised by owner. Now I have given you an idea of what is really wanted on road, and I feel sure you will take the criticism in the spirit it is given, for, as you know, the lookers-on often see the most of the game. One thing I strongly recommend you to adopt is magneto-ignition. I can speak from experience that it licks batteries into the proverbial cocked-hat.

Monty.

[42886.]—SKETCH shows an improvement for small motor pistons that have been designed since complaints against not getting sufficient oil on top bush, also to save weight. It may be useful to those engaged in following present articles. It is of malleable iron cut down to thinnest possible dimensions. The top, being dished for strength, also allows oil to run to point of small inverted cone, which must be cast on in one, not screwed in. Sides of piston cut away to save weight, which it does considerably. It wears very well in actual work, and gives no trouble, cast-iron rings being used. It may be further lightened by using two rings only, which would cause less side friction, but would not keep tight so long. The top bush is of manganese bronze, which I have since adopted on every bearing of engine, being far superior to steel or anything else I have tried so far; engine gives better results, and there is less liability to seize. In fitting bronze bushes they must be left a trifle slacker than if steel was used, owing to rapid expansion under heat. The split cottar shown to hold crosshead pin in prevents any danger of same working out, and scoring cylinder; it is far superior to method of having screwed pin to secure it.

Monty.

AERIAL LOCOMOTION.

[42887.]—I HAVE to inform "Eureka," in reference to his letter (42864), that which he takes as confusing in my former letter arises from a printer's error. Instead of "3H.P. per 100lb.," it should have been "3H.P. per 100lb. raised" (read one hundred pounds). This amount of power related to the free flight of an aërial screw, and was recorded because the force could be easily computed. I stated in my essay of 1866 that the result was only approximate: it is enormously in excess of the real power required to sustain a weight on a wing surface, which force may be moderate, judging from the flight of the largest and heaviest birds. A screw when first spun off, has its vanes suitably adjusted for a high speed. As this diminishes, so does the power required to sustain increase, for it is a condition in flight that the higher the speed the greater the economy in power. If a flying machine was to be made with the idea of acquiring a low speed, say of four or five miles per hour, not by any command of motive power applied, either by flapping wings or vertically-acting screw-blades, would it be possible to keep it sustained. The absolute condition of continued flight must be rapid horizontal progress through the air: then we can get nearly a solid support, on the inertia of a large extent of aërial mass. I believe that every construction of a machine for flight has been deficient in stability, and this has been the main cause of failure. I once made a model that would glide steadily away to a distance of twenty yards, or more, without capsizing. I requested an aëronaut to take it up in his next balloon ascent, and then set it free, in order to ascertain how far it would travel away. It kept its equilibrium for a short distance, and then suddenly tripped and turned rapidly over till it reached the earth. Some compensation for stability was needed. We see how readily a bird can adjust itself. A tumbler pigeon, for mere frolic, will turn a series of somersaults in the air, and if a carrier pigeon is thrown with the tail first or legs upwards, this makes no difference, the bird feels the air and rights itself instantly.

F. H. Wenham.

THE CONQUEST OF THE AIR.

[42888.]—IN reply to "Eureka," letter 42864, p. 139, it would obviously facilitate a more favourable reply if he gave a more definite description of the size or weight, if not a fuller description, of his models. Models by the score have flown before this, but at the same time they do not conclusively show that the problem of aviation is solved. For instance, a boy's kite is a model of the aëroplane, and Prof. Langley's experiments with his aërodrome, in which a small model flew nearly a mile until the power was exhausted, whilst instructive, are to the trained mind quite inadequate sources of logical proof. For small experimental models, electricity is undoubtedly far preferable where lightness is essential.

E. Wilson.

MICRATOMIC ETHER.

[42889.]—IN reply to W. Howse (42825), yes, the pitch of sound is analogous to the colour of light, both being the effect of the number of vibrations in a given time set up in their respective media.

I presume the question is asked in order to show a likeness between a material medium and the ether. There are many others; for instance, sound can be refracted and reflected, it exhibits the phenomenon of interference, and its rate of propagation is subject to the same laws (with regard to the elasticity and density of the medium) as that of light.

In fact, I believe the only supposed point of difference is in the matter of "polarisation," and I cannot find any record of what experiments have been carried out to prove this: hence my letter of inquiry, which I trust some reader will be able to answer.

R. A. Kennedy.

METALS MADE PLIABLE BY TAURIC ACID.

[42890.]—THE following statements I found in an American paper (dealing with science according to its title); but I cannot find any further information, so appeal to readers of the "E.M." The article reads:—

Another discovery is claimed that, if true, bids fair to give as important results in the world of science as any that has been made in many years. It is the result of experiments carried on by Theodore Olan, a Swedish chemist at Washington, and, like many others, it was found by the merest accident.

Mr. Olan's discovery consists in finding a new agent which will soften steel, gold, silver, and many other metals, making them soft, pliable, and ductile as a piece of putty, and quite as easily and safely handled. He has named the new chemical agent tauric acid, because it is obtained from tauric moss, a peculiar lichen, or fungus, which grows upon rocks and roots of trees very generally in the country, but it has never before been the subject of chemical investigation. The new acid has been tested by many eminent chemists in the country, who pronounced Mr. Olan's discovery to be one of the wonders of the world of chemistry, and it is believed that it has a great and important future before it in the arts and sciences. It is remarkable that the discoverer has given it gratuitously to the world.

Mr. Olan gives the processes that led to the results reached by saying that while making some experiments with tauric moss in his laboratory he found the bottom of the metal dish he was using became soft. At first he supposed the dish had been partially decomposed by other acids, but upon investigation he proved this was not the case, and fully satisfied himself that the change was caused by tauric acid, and this led him to making experiments which fully verified his opinion. He says: "By placing gold, silver, steel, aluminium, or lead in this acid I found they became soft as dough, so that they might be worked with the hands into any shape or form. Although steel softens readily when placed in a vessel containing tauric acid, strange to say, the acid has no effect upon iron. Tauric acid will be of great value to jewellers in making designs in precious metals. Designs may be moulded or

beaten to the required shape without heat being at all."

The process of making the acid is very simple and inexpensive. Mr. Olan describes it as follows: "My plan for bringing out the acid from the tauric moss is to put in a deep vessel a layer of chloride of lime, then a layer of tauric moss, to the depth of 2in., and then a layer of chloride of potash of about the same thickness. This is saturated with water until the lime is slaked away. After the fire has gone out of the lime the liquid is drawn off. After this, creosote of tar is added until a saturated solution results. The solution is precipitated with a solution of sulphuric acid, one part in ten. After precipitation the supernatant liquid is decanted, and the residue is found to consist of pure tauric acid."

Can any American reader tell me what is this wonderful moss, or is it another joke? **Wideo.**

IMPROVEMENT IN ROTARY ENGINES.

[42891.]—IN this week's issue (p. 131) is a section and elevation of an "Improved Rotary Engine," but it, as with the twin steamer and the roller steamer, so prominently brings to my mind the astonishing fact that as the cycle of years roll on modern men repeat the same work which earlier men have found to end in failure.

As long ago as when the screw steamer *Archimedes* was lying in the East India Docks, a Counsel named Brenton had an identical type of rotary engine (except on that the two pistons were connected together) in a screw steam launch, and with this steam-launch and rotary engine I made a series of trials of several forms of screw-propeller. To change the several forms of propeller, the stern of the launch was lifted out of the water with suitable gear attached to the yard-arm of the *Archimedes*.

Then following this Mr. Wimshurst adopted a similar engine for the s.s. *Novelty*, the little difference being that it had four pistons, instead of the two used by Brenton, and now shown in your plan. With this rotary type of engine the s.s. *Novelty* made her first commercial voyage.

It would take too much of your space to explain all the causes of failure in both of these engines; but Mr. Wimshurst soon after patented a somewhat similar type of engine having six pistons. This engine was fitted in the s.s. *Zingaree*, and one day I was on board her when she beat the p.s. *Meteor* upon the run from Gravesend to Blackwall.

Your readers may therefore suppose there is abundant reason for inquiry before they become infatuated with the modern design. **J. W.**

VASO-DILATORS.

[42892.]—IT has been known for perhaps some ten or twelve years that nitro-glycerine causes rapid dilatation of the arteries, and, therefore, usually gives prompt relief against the heart-strain of angina pectoris. This effect soon passes away, and the liability to the heart-pain then returns. To Prof. Bradbury, of Cambridge, it seemed likely that among a certain group of nitrate compounds, beginning with methyl nitrate, and passing through nitro-glycerine to erythrol tetra-nitrate and mannitol hexa-nitrate, we might find some one having a longer vaso-dilating effect, and on undertaking experiments which were detailed in the *British Medical Journal* of Nov. 16, 1895, p. 1213, he found, in erythrol tetra-nitrate especially, such a compound as he was searching for, its action lasting for four or five hours. What a boon this is to those who would otherwise be roused from sleep in the night by this agonising suffering cannot be told. It has occurred to me that the same knowledge of organic chemistry which led Prof. Bradbury to experiment with this particular series of nitrates may indicate other groups, among which there may be substances capable of causing still more prolonged vessel-dilatation than the erythrol tetranitrate. Can any chemist kindly say what is the prospect of there being such? Are there other lines or series of nitrate or nitrate compounds, many or few, along which substances acting in the same way, and even preferably, may be hopefully looked for? I ask in great ignorance of organic chemistry, and the question can evidently be answered only by those whose knowledge is of an advanced kind.

A word also would be acceptable as to the process by which erythrol tetra-nitrate is prepared, and why the charge made for it is so very high.

THE STEREOSCOPE.

[42893.]—THE method of uniting stereoscopic pictures mentioned by "R. S. D." in his letter, by looking at the left-hand picture with the right eye, and *vice versâ*, gives, as he says, pseudoscopic effects, unless the pictures are mounted especially for the purpose, the right-hand half of the slide being changed to the left.

A print from a binocular camera negative gives the pictures in this position. It is, however, quite possible to see ordinary stereo slides in the way I mentioned without squinting outwards, as he suggests. The diagram annexed will show this to be the case.

I have for the sake of clearness given an exaggerated width in proportion to the lengths, as it will have to be copied on a smaller scale for publication. Supposing R and L to be the position of the eyes, *r*, *d*, *l*, two pins stuck upright and a third pin stuck in at P, it is evident that looking with the right eye the pin *r* will appear to cover the pin P, and looking with the left eye the pin *l* will do the same.

On looking with both eyes, slightly squinting, the heads of the pins will appear to unite at that point, and if small stereoscopic pictures, the centres of
